Under rectal ether with some chloroform on a mask as required, a laparotomy was done, and on the anterior wall of the stomach very near the lesser curvature, and about 2 inches from the pylorous, an ulcer was found and demonstrated to the nurse. It was round, with a definite edge moderately hard, and the crater admitted the tip of my little finger. Some adhesions stretched from the peritoneal surface of the base of the ulcer to the liver. A posterior gastro-jejunostomy was done and the incision closed. He passed tarry stools for three days, but thereafter his recovery was uneventful and rapid. He was put on to alkalis. He gained rapidly in weight, so much so that his scar was stretched to an inch in width. When I saw him two years later he had put on 2 stones in weight, had no pain, and was thoroughly satisfied with himself. He had not needed to work because the story of "how we did it" would always secure him a meal.

While this complaint cannot be common, its frequency is difficult to estimate. These people are used to disease, and consider such things as fever and yaws as part of their normal lives. It was only the severity of the symptoms of the above case which made him come for treatment. Those with less discomfort would not come. Anæsthetics and operations were a very new thing and to be avoided if possible.

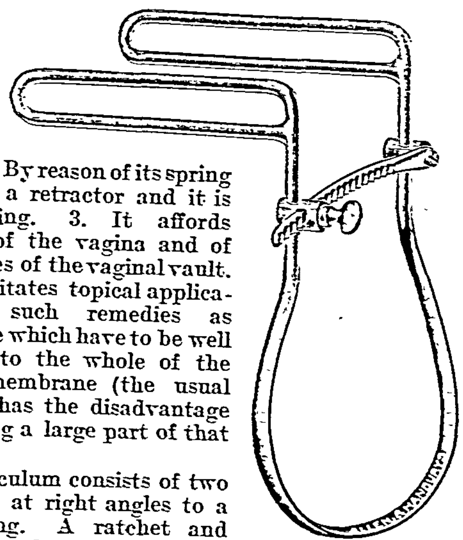
Amongst these people, furthermore, there are factors which would predispose to peptic ulceration. Malaria causes anæmia and a generally lessened resistance to disease. Ulcers occur in other sites, particularly the skin, with the greatest of ease. Their food is coarse, mostly vegetable, and consists of taro, yam, sweet potato, banana, tapioca, and—in times of stress when the gardens are poor—coconut, which is poorly chewed, and is swallowed in lumps. All their foods are insufficiently masticated. Chewing is a waste of time. Their meals are often huge, and are taken at more or less irregular intervals. The diet is unbalanced, and except for a little fish is of necessity vegetarian. Pyorrhœa as has been stated is very common, the gums exuding pus, and the teeth becoming prematurely loosened, and dropping out. Malaria, while lessening the resistance of the patient, also damages the lining of the stomach. The subtertian parasite, by sporulating in the gastric vessels, causes congestion, thrombosis, and subsequently bleeding into the stomach.

On the other hand, the malaria which does the damage to the blood and to the stomach also lowers the gastric acidity, as many as 26 per cent. of patients having achlorhydria. While pyorrhœa is so common, caries and apical abscesses are rare, and correspondingly, bacteria in the blood from that source are rare also. Nasal sinus involvement is not uncommon, but septic tonsils are not common. Betel nut is also a factor. This nut is most unpalatable if taken alone, but when combined with lime it loses its acridity, turns red, and becomes palatable. The amount of lime that is used is considerable, and while a good deal is ejected, as with tobacco-chewing, a fair amount must be swallowed. These folks are not heavy smokers, as the white man considers smoking, but they are much subject to cold and damp. Few have blankets, and most spend the night lying alongside a small fire, which is renewed when the chilliness has awakened the sleeper.

NEW INVENTIONS

SELF-RETAINING VAGINAL SPECULUM FOR TOPICAL APPLICATIONS

THIS speculum which is in use at the Tuckingmill Venereal Diseases Clinic serves the following purposes: 1. It is readily introduced into any sized vaginal orifice. 2. By reason of its spring it acts as a retractor and it is self-retaining. 3. It affords full view of the vagina and of the fornices of the vaginal vault. 4. It facilitates topical application of such remedies as urochrome which have to be well rubbed into the whole of the mucous membrane (the usual speculum has the disadvantage of covering a large part of that surface).



The speculum consists of two blades set at right angles to a bow spring. A ratchet and screw fixes the blades in position after insertion. The blades are four inches long and three-quarters of an inch wide, but fenestrated.

The instrument has been made for me by Messrs. Allen and Hanburys, Ltd., Bethnal Green, E.2.

C. H. RIVERS, M.D., M.R.C.P. Lond.

NEW WESTMINSTER HOSPITAL.—As a precaution against flooding the new medical school and nurses' home at this hospital are to be built on a typical old Thames site. The basement will be a great watertight concrete-asphalt tank nearly 100 yards long, 30 yards wide, and 5 to 7 yards deep. Nearly 200 concrete blocks placed over the floor of the tank will support main stanchions on which the building will rise to a height of over 100 feet from the basement level to the motor-house on the flat roof.

REVIEWS AND NOTICES OF BOOKS

Epidemics and Crowd Diseases

An Introduction to the Study of Epidemiology. By MAJOR GREENWOOD, D.Sc., F.R.C.P., F.R.S., President of the Royal Statistical Society; Professor of Epidemiology and Vital Statistics in the University of London and London School of Hygiene and Tropical Medicine. London: Williams and Norgate. 1935. Pp 410. 21*s*.

THIS book is unique in its approach, the emphasis, as indicated in the sub-title, being laid on the *study* of epidemiology. Prof. Greenwood traces the evolution of ideas on the subject, the part played in these developments by workers in the past being described in a way which captures at once the reader's interest and attention. The book will be found of little value for examination purposes or as a work of detailed reference; it contains no ordinary descriptions of notifiable infectious diseases arranged under the customary headings of incubation periods, infecting organisms, predisposing factors, differential diagnosis, age and sex variations of incidence and fatality-rates, prophylaxis, and treatment. But the reader will gain from it some idea of the methods of approach to the general problems of communal medicine, and—perhaps more important—he will begin to realise something of the vital interest and importance attaching to the skilful analysis of masses of statistical data and the intelligent synthesis of the findings. The author builds upon solid foundations, e.g., the futility of speculation as a means of arriving at the solution of problems, the realisation of the need for basic data, the practical necessity for new and more appropriate technical methods of analysis, and, finally and fundamentally, the application of the principles of ordinary logic to the results. The teaching is clothed in his usual lucid and pungent style.

Prof. Greenwood traces the evolution of epidemiological thought from the times of Hippocrates and Galen, through the age of Graunt and the dawning of interest in the collection and analysis of mass statistical data, to those more recent times in which the knowledge of bacteriology and technical methods of examining data have assisted so materially in the approach to epidemiological problems. In spite of such advances in knowledge and technique, the failure to elucidate the fundamental laws of epidemiological visitations in human experience and the realisation of our essential ignorance of the grammar of the subject ("human populations," the author says, "will not stay put") led to the latest development of investigation upon the simpler and more easily controlled populations of lower animals—an advance with which the author's name is intimately connected. These introductory chapters depict the giants of the past with illuminating sidelights on their personalities, and afford a clear view of the stagnation and periodical spurts in the general advance of knowledge along this path. Three chapters on predisposing factors in communal sickness — nutritional, occupational, and psychological—round off the general part of the book. Representative groups of "crowd" diseases are then dealt with historically and descriptively. Classical epidemics, their investigation, and the reasons for the conclusions reached, are instanced, and the problems of the statistical epidemiology of each discussed, the whole exposition indicating what can be learned of the crowd from this point of view, and how such learning is to be attained. A departure from the usual conception is the inclusion in the discussion of such diseases as tuberculosis, cancer, and venereal disease.

The volume is a contribution to the science of epidemiology which will command earnest and thoughtful study by all students of human health.

Gastritis and its Consequences

By KNUD FABER, M.D., F.R.C.P.E., Hon. Professor of Internal Medicine in the University of Copenhagen. London: Humphrey Milford, Oxford University Press. 1935. Pp. 119. 8*s*. 6*d*.

Prof. Faber has for so long been the champion of that school which emphasises the importance of gastritis that he may well look upon the present decade as one of triumph for his views. Gastritis excites more and more interest in the medical world; it is one of the principal subjects chosen for discussion at the International Congress on Gastro-Enterology being held in Brussels during this week, and the increasing popularity of gastroscopy has added a vast amount of new information on the subject. In this book, which is based on three lectures given at Guy's Hospital in 1934, Prof. Faber summarises his ideas on the whole subject. Many beautiful low and high power microphotographs are included, and the monograph provides strong evidence in favour of his main thesis, which is that gastritis is such a common disease that it is very rare for a normal stomach to exist in an adult person. From this thesis the author goes on to develop the theme that gastritis is a very important ætiological factor in the production of peptic ulcer, and later that gastritis is the all-important cause of anacidity. His inquiries at the University Clinic, Copenhagen, do not support the view of A. F. Hurst that hyperacidity and anacidity are largely a matter of diathesis; he believes that inflammatory disease rather than any inborn or constitutional factor is the important cause of anacidity and hence of pernicious anæmia. As regards cancer of the stomach, on the other hand, he believes that a constitutional or hereditary disposition is of greater importance in ætiology than the presence of gastritis.

This monograph, from one who is, perhaps, the principal exponent of the "gastritis" school, does not impress as entirely convincing. Many lacunæ remain to be filled up before peptic ulcer and pernicious anæmia can logically be placed in the same pigeon hole. The evidence as to the frequency of gastritis is certainly striking, but its acceptance carries with it the corollary that gastritis if very common must often be symptomless.

Diabetes Mellitus and Obesity

By GARFIELD G. DUNCAN, M.D., C.M. (McG.), Associate in Medicine in the Jefferson Medical College, Philadelphia; Assistant Physician to the Pennsylvania Hospital; Chief of the Metabolic Clinic of "B. Service," Pennsylvania Hospital. London: Henry Kimpton. 1935. Pp. 215. 12*s*. 6*d*.

Dr. Duncan, who worked at one time under Dr. F. M. Allen, has written a book which will be very useful to doctors looking after diabetic patients. The physiology and pathology of the disease are clearly described, and the way the diet is arranged is fairly simple, though the food value of vegetables, fruit and so forth are given in percentages instead of in the much more convenient five gramme method. The instructions for the care of the feet, in order to reduce the risk of gangrene, are very detailed and contain much valuable information. The differential diagnosis between coma due to hyper and hypoglycæmia is very well set out, and stress is laid on the necessity of getting rid of the ketones in diabetic coma as soon as possible. This is accomplished by giving glucose as well as insulin at frequent intervals. A simple way of testing for the presence of acetone bodies in the blood by means of the Rothera reagent is described.

The second part of the book (41 pages) is devoted to an interesting account of obesity. It is estimated that one-fifth of the population of the United States is overweight, and that diabetes is ten to twenty times as frequent in fat people than in those of normal weight. According to this, then, the prevention of diabetes in the elderly people depends largely on the reduction of the number of people who are overweight. A succinct account is given of the causes of simple obesity where no endocrine disturbance can be made out, and the relation of heredity, age, race, sex and occupation. The principles on which a reducing diet is constructed are clear, stress is laid on the importance of not reducing the calories provided by the carbohydrate below one-third or half the total calories of the diet. The specific dynamic action of protein is of little value in increasing the metabolism of the foods in obesity, and it is unnecessary to give large amounts of protein. The fat can be reduced to a small amount. The foods which contain low, moderate and high calories are given in three parallel columns. They do not seem well adapted for the purpose of enabling the patient to choose a diet containing the correct balance between carbohydrate, protein and fat. Some useful tables are appended.

Growth and Distribution of Population

By S. VERE PEARSON, M.D., M.R.C.P. London: George Allen and Unwin. 1935. Pp. 448. 12*s*. 6*d*.

THE main theme of this book is that the proper growth and the rational distribution of population has been hampered throughout the ages by the private ownership of land. The indictment of landlordism is powerful, and the unbiased reader will be impressed with the evils inherent in a system which allows a man through no effort of his own to profit greatly when he happens to own a site which the efforts of the community have made valuable. Dr. Pearson's survey of land tenure extends historically from neolithic times to the present, and geographically from the swamps of Central Africa to modern New York. The remedy suggested is that the ownership of the land should revert to the community (with suitable compensation to landlords in particularly hard cases); rent would then become payable direct to the State and would be sufficient in amount to make other forms of taxation unnecessary. If free access to land were available the author considers that this country would support a rural population, about three times as numerous as at present, who would devote themselves to the intensive cultivation of the land.

In addition to landlords, Dr. Pearson detests contraceptives and water-closets. In the ideal world which he visualises the former would be made unnecessary on account of the greatly increased population which properly used land would support, and these teeming millions would increase the fertility of their fields with the contents of earth-closets from which some fastidious Chinaman had taught them to eliminate all traces of smell. It is also claimed that the abolition of the landlord, by giving the common people free access to land, would cure unemployment and abolish war. It does not require a statistician to perceive that the alternatives of birth control or civil war would arise after a time in any such community, though the calculation of the period during which peaceful expansion would be likely to endure might be difficult even for experts. Not many of Dr. Vere Pearson's readers will share his faith, but all will find stimulus as well as much information in his pages. For a physician who has reached a prominent position in his own branch of medicine to find the time and surplus energy to tackle so difficult a problem of sociology is in itself no mean achievement.

Dietetics for the Clinician

Second edition. By M. A. BRIDGES, B.S., M.D., F.A.C.P., Director of Medicine, Department of Correction Hospitals; Consulting Physician, Seaview Hospital, New York. London: Henry Kimpton. 1935. Pp. 970. 45*s*.

THIS book contains a wealth of information on dietetics which will be valued by English readers. The opening section on the mechanics of digestion is so condensed as to be of small value, but the following chapters, dealing with physiology, vitamins, and the composition of foods, are well written and up to date. The later chapters of the book dealing with the treatment of various diseases by diet contain the views of well-known American authorities such as H. O. Mosenthal, H. W. Blake, and N. T. Saxl. The description of the dietetics of each disease is preceded by a brief description of the pathology and clinical manifestations which is usually very well compiled. It is to be regretted that the differences between British and American menus robs this excellent volume of much of its utility for the English practitioner. The book ends with thirty pages of bibliography and excellent indices.

Pharmacological Action of Harrogate Drinking Waters

By WILLIAM BAIN, M.D. Dunelm, F.R.C.P. Lond., F.R.C.S. Edin., Editor of "A Text-book of Medical Practice." London: J. and A. Churchill Ltd. 1935. Pp. 53. 5*s*.

IN this little book Dr. Bain presents the results of his investigations of the pharmacological action of a number of the waters obtainable at the Harrogate spa. These fall into two main groups, the sulphur and the iron-containing or chalybeate waters, each of which can be further subdivided according to the tonicity of the water compared with the body fluids. His experiments show that on an isolated strip of the rabbit's intestine most of the waters cause an increase in movement with, in some cases, an increased muscle tone, while the intravenous injection of many of the sulphur waters into a pithed animal results generally in an increased movement of the stomach and intestine, and an increase in the tone of the pyloric and ileocolic sphincters. The chalybeate waters have no such effect. His observations on the cholagogic action of the waters lead him to the conclusion that the old sulphur spring water increases both the quantity of bile and the bile solids, while the strong Montpellier spring water diminishes them slightly. On the isolated rabbit's heart the chalybeate waters produce an increase in systolic contraction and cardiac output, and in the intact animal his experiments suggest that the effect of a mild isotonic sulphur water is to relax the cardiac muscle without any change in cardiac amplitude or blood pressure.

These experiments are interesting, but it is a little doubtful if they warrant the conclusion drawn by the author that Harrogate ought to specialise and concentrate upon two different sets of diseases, viz., affections of the alimentary tract, including the liver, and diseases of the heart. It is difficult to be sure that waters given, as they usually are, by mouth will produce the same effect as they show on isolated tissues or when administered intravenously, and it is by no means certain that an increase in the flow of bile is of much therapeutic importance in most diseases of the liver. In any case, the most powerful known cholagogue, bile itself, is always available. But any serious attempt to lend precision to spa treatment by exact pharmacological experiment is to be welcomed, and we commend Dr. Bain's book to the attention of those interested in the future of our spas.

Pflanzliche Therapie

By Dr. ERNST MEYER, Oberarzt der Inneren Abteilung des Städtischen Krankenhauses, Berlin-Spandau. Leipzig: Georg Thieme. 1935. Pp. 202. R.M. 4.80.

THIS little book deals with the treatment of disease by the internal administration of drugs obtained from plant sources. It attempts to revive interest in the galenical preparations, and may serve a useful purpose on the continent in drawing attention to the fact that drugs may usefully be given by other routes than by intravenous and subcutaneous injection. The first part of the book provides an interesting review of the history and development of plant therapy. In the second part the author deals systematically with the applied pharmacology of plant extracts, while in the third he gives examples of prescriptions classified according to disease of the various systems. While to the ordinary reader many of the drugs advised may be unknown, and the rationale of the use of others be in doubt, the specialist will find the book of considerable value.

A Doctor Talks

By JAMES MCDONNELL, M.C., M.R.C.S. Eng., L.R.C.P. Lond. London: George Newnes Ltd. 1935. Pp. 126. 5s.

THE author's excellent purpose is to persuade the patient to go to his doctor for a diagnosis rather than to the chemist for symptomatic treatment. The style is simple and colloquial; the standard of erudition demanded of readers rather lower than that in a first-aid manual. The hypochondriac, only too often an amateur doctor, will not be satisfied with such elementary stuff and the general public will only find herein that little knowledge which is a dangerous and alarming thing. Dr. McDonnell is at pains to point out that he is not trying to "put the wind up" the reader but at the same time adjures him to make a business of his health—surely redundant advice in this neurotic age. "Fouet's" little humorous sketches are attractive and recall those of Mr. Reynolds in "1066 and All That."

Quarterly Journal of Medicine

IN the July issue (vol. iv., new series) J. S. Westwater (London) gives the results of his study of tuberculin allergy in acute infectious diseases. Now that the Mantoux test has almost superseded the method of Pirquet in clinical work, it is clearly important to know of any condition which may influence its results. The possible suppression of the tuberculin response was investigated in 2000 cases of acute infections, including measles, scarlet fever, chicken-pox, diphtheria, and pertussis. Measles and scarlet fever appeared to cause a temporary depression of tuberculin sensitivity lasting for about a week from the appearance of the rash, and this was thought to be due to the patient's sensitivity having fallen below the reaction threshold as a direct result of the action of the rash on the skin itself. The importance of repeated tests before a negative result to a given dilution could be accepted was clearly demonstrated.—Since loss of weight is one of the commonest precursors of a relapse in juvenile rheumatism, E. C. Warner and F. G. Winterton (London) have made a dietetic study of this disease. They found no signs of undernutrition in rheumatic families as a whole and the rheumatic children were up to the normal standard of physical development for English school-children, though the parents thought their appetites not so good as those of the non-rheumatic. Confirmation was obtained for the mother's statement that the rheumatic child was less fond of meat and fresh fish than the normal child; it also seemed that an increase in animal fat in the form of butter and milk was of prophylactic value. There appeared to be no lack of vitamin-C intake by children in rheumatic families, and the provision of extra vitamin A and D had little or no preventive action.—W. R. Snodgrass (Glasgow) report on the therapeutic use of iodides in the treatment of syphilis. On a basis of 1750 cases he was able to show that iodides had no effect upon the spirochætal content of the lesions of primary and secondary syphilis, but that they caused the resolution of tertiary skin lesions. The optimum dose appeared to be grs. 15 thrice daily, but resolution was accelerated by a single big dose orally or a dose intravenously. Iodides had no influence on the Wassermann réaction in any stage of the infection; iodism could be stopped by an intravenous dose of sodium iodide.—G. R. P. Aldred-Brown and J. M. H. Munro (Bath) have inquired into the connexion between the amount of albumin, globulin, and fibrinogen in the blood-plasma and their ratio to the total proteins, in chronic rheumatic disorders. They report wide variations in the value of the protein. the total protein and the non-protein nitrogen between healthy adults, patients with chronic rheumatic disorders and non-rheumatic persons whose ages and economic stresses were more or less comparable.—E. M. Watson and Marion A. Wharton (London, Ontario) have scrutinised the various dietary measures which have been advocated for diabetes. They hold that no universal rule applies; the type of diet best for a particular patient has to be governed by individual requirements. A high-fat, low-carbohydrate diet lowered or eliminated the insulin requirements of many patients, but it tended to reduce carbohydrate tolerance and favour ketonuria. Conversely, a rise in carbohydrate, provided the fat was kept low, did not necessarily require increased insulin dosage, since it improved tolerance.—Leslie Cole (Cambridge) writes on the treatment of tetanus, with observations by E. T. C. Spooner. This paper was reviewed in a leading article last week.—R. D. Passey and J. McD. Holmes (Leeds) approach the problem of the possible increase in intrathoracic neoplasia from a new angle. They do not think such an increase has been appreciable; nor do they find reason to incriminate the ætiological factors suggested by those who believe the incidence to be rising.

THE LANCET

LONDON: SATURDAY, AUGUST 10, 1935

THE DOCTOR AS ADMINISTRATOR

In the administration of medical services of any kind many affairs of a non-medical character have to be handled. Purchases have to be made, incomes assessed, moneys collected, clerical staffs controlled, and clerical work organised. Lay staffs of various categories are engaged, put to work and supervised. Often, as in the department of a medical officer of health, the lay staff far outnumbers the medical, and in his daily routine the head of the department is concerned with little that is ordinarily regarded as lying within the province of medicine. Is he the sort of officer whose training makes him best suited for the purpose? Or would a lay official at the head of the department be more efficient? Or should a medical officer remain in charge of purely medical affairs, while those of a non-medical character are dealt with by a completely independent officer specially trained in administration? The Hadow Committee, which reported in 1934, addressed itself to problems of this kind in relation to all branches of local government. While suggesting that "local authorities should not always take it for granted that the principal officers must necessarily be technically qualified," it was unable to recommend that any radical change of the existing system was desirable or practicable.[1] There is a tendency on the part of impatient critics to lay too much stress on small flaws in the machinery of administration and to suggest changes which overlook the objects it is intended to achieve. If administration means more than mere business management, handling correspondence, record keeping, filing, supervision of lay staffs, and a close scrutiny of expenditure, if it means the application of scientific knowledge to the betterment of the lives of the people, the guidance of technically qualified assistants, the conveyance of a department's collective experience to those who determine policy, and the application of such policy to the day-to-day work of the department, a professionally qualified head is surely best fitted for the purpose. The Hadow Committee commended the arrangement, already operating in some areas, whereby a senior (but subordinate) official is appointed as a lay administrative officer. This type of appointment appears to have worked well in Manchester and other towns where it has been tried. The chief clerk of any health department is virtually in this position, and it is desirable that the qualifications and training for such posts should be defined and the scales of remuneration sufficient to attract capable officers.

Since the transfer of poor-law functions in 1930, the relation of medical and lay officers in hospitals has been added to the problems of local authorities. The executive officer of a mixed institution is the master, a layman, to whom the medical officer is administratively responsible. Difficulties have frequently arisen in the past and some authorities have overcome them, with the sanction of the Minister of Health, by appointing the medical officer also to be master of an institution which contains a large proportion of sick inmates. There are legal obstacles to this subterfuge but they are not insurmountable, since the Minister may sanction "departures from the regulations." [2] In poor-law hospitals, as distinct from institutions, the medical superintendent quite definitely "governs and controls the hospital and the officers, assistant officers, servants and inmates." [3] Although the steward has specific responsibilities, there is no question as to who is the chief official, since the steward's reports must be submitted through the medical superintendent.[4] This is not a new state of affairs dependent upon the passage of the Local Government Act, 1929, but the tendency to appropriate parts of institutions for medical uses, or to introduce medical control by unification of the appointment of master and medical officer in one person, may account for the discontent among lay officers which has recently been expressed. Thus, according to reports in the lay press, at a meeting of the National Association of Administrators of Local Government Establishments (a rather comprehensive designation) it was contended that a lay administrator should be solely responsible for the departments of supply, maintenance, accounting and recording other than purely medical statistics. It was suggested that many medical superintendents regard stewards of hospitals as nothing more than "glorified office bosses." The idea underlying these and similar protests seems to be that medical men should have no responsibility for non-medical administration in hospitals and that a lay officer should be answerable in such matters directly to the governing body. We sympathise heartily with the desire to relieve medical officers of details of lay administration and commend the Hadow Committee's suggestion to the members of this Association, believing that it is in accord with the arrangement which already obtains in most local authority hospitals and with the requirements of the Public Assistance Order. The Association appears to be anxious to collaborate with the Society of Medical Officers of Health [5] who may be able to assist them in the removal of any real grievances.

Good administration, however, requires that there should be one administrative head of a hospital, who, in the last issue, shall take decisions and justify them to the governing body. The functions of a hospital are the treatment of the sick, the advancement of medical knowledge, the training of nurses, and often the teaching of medical students. All problems of administration are ancillary to these objects. What is done and what is bought are more important questions than executive methods. The well-being of the patients and the conditions under which the staff work and learn depend upon the comprehension of the hospital's objects by its administrative head. Clearly these will be attained best under medical administration, provided that medical men—or women—are selected for appointment because of their fitness for this kind of work, and relieved from details not only of lay administration but also of a clinical character. We believe, therefore, that the practice which prevails in local authority hospitals should continue. If it is true, as Dr. R. Worth stated at a recent meeting of the Royal Medico-Psychological Association, that there is a move on foot to oust the medical superintendent from control of mental hospitals, we hope that it will fail. Further, in that pooling of knowledge and experience which the Act of 1929 was intended to foster, the voluntary hospitals might learn something in this respect from the council hospitals. Outside of Scotland, and with the exception of a very few hospitals in England and Wales, voluntary hospitals have favoured lay administrators. An unprejudiced examination of the relative merits of the two systems by governing bodies of hospitals might lead them to a different point of view. If the voluntary hospitals are to survive, their defects of administration which the developing council hospitals are throwing into relief must be corrected, and medical administrators would be quick to put their fingers on them and force them upon the notice of the managers.

LATENT TUBERCULOUS PERITONITIS

Notable advances have recently been made in the diagnosis of early tuberculous disease and radiology has enabled us to overcome difficulties that but a few years ago appeared to be insuperable. The diagnosis of incipient tuberculosis in joints or bones has been simplified by radiology, and the same means of investigation enables us to diagnose early pulmonary lesions with a confidence and accuracy which a few years ago was impossible. But no such confidence attends our efforts to diagnose abdominal tuberculosis, whether the result of a primary or of a secondary infection. Autopsy may reveal an extensive ulceration of the intestines in a consumptive, although such a condition was entirely unsuspected during life. Laparotomy for an acute appendicitis may reveal a peritoneum studded with tubercles in a patient who was apparently in good health up to the day when acute symptoms developed. The student is taught that tuberculous peritonitis may be acute, subacute, or chronic, that there is an ascitic and a plastic form of the disease, that operation will mysteriously cure the one and less mysteriously fail to benefit the other. A wasted frame and a protuberant belly which provides interesting signs of shifting dullness, or a thrill that may be flicked from one flank to the other under the steadying hand of a colleague, supply evidence of ascitic disease. Cachexia, fever, abdominal discomfort, and bowel irregularities, associated with a "doughy" sensation when the abdomen is palpated, suggest the plastic form. In either instance the disease is one which impresses the mind, and to the fifth-year student the diagnosis of abdominal tuberculosis appears to be a fairly straightforward matter.

In general practice the problem is found to be by no means so simple. An ill-nourished and anæmic-looking child complains of abdominal discomfort, the clinical thermometer registers a low fever, an anxious mother suggests "consumptive bowels," and if her diagnosis is not accepted demands to be informed "what really is the matter with the child." Physical signs are unhelpful and home treatment seems unavailing. The easiest method of dealing with the case is the notification which provides a short cut to a children's sanatorium. If the patient is admitted to a sanatorium, despite prolonged observation and searching investigations, evidence of tuberculosis is seldom forthcoming in cases of this type. Indeed, more often than not a regimen of correct feeding, regular hours and adequate rest results in a rapid amelioration of symptoms, which do not recur until the child returns to the slum tenement or farm labourer's cottage from which he came. Though admissions of patients reputed to be suffering from abdominal tuberculosis are frequent, very few patients retain a diagnosis of tabes mesenterica or tuberculous peritonitis when they leave the sanatorium. As the abdomen contains the digestive system it is not surprising that symptoms arising from digestive disturbance are referred to it and that abdominal discomfort is usually correlated with wasting or malnutrition. The child who suffers from chronic intestinal catarrh may complain of pains, suffer with constipation and fail to gain weight. Flatulent bowels and under-nourishment often suggest, they seldom imply, tuberculous disease. But though a diagnosis of tuberculous peritonitis is often made on insufficient grounds, it is possible that the disease is sometimes overlooked, or its symptoms disregarded until exacerbation of disease or a superadded infection results in its discovery. Laparotomy performed in the early hours of an acute illness may reveal tuberculous lesions so widespread that, unless tubercles grow like mushrooms overnight, we are driven to the conclusion that lesions—the term disease is in some cases inapplicable—have been present for a period of weeks or even months at the time of their discovery.

It has for long been recognised that inflammation of the appendix may be due to an infection by Koch's bacillus and the tuberculous origin of a chronic appendicitis or perityphlitis may sometimes be suspected from the patient's appearance, from the clinical picture, and the physical signs in the abdomen. Laparotomy may confirm the diagnosis and reveal the tuberculous origin of the disease at a glance. A Rumanian surgeon, Dr. At. Janes has recently drawn attention[1] to a curious phenomenon sometimes encountered in patients who have received treatment for "surgical" tuberculosis and who develop symptoms of acute appendicitis. Operation in such cases may reveal an appendix inflamed or containing pus and exhibiting no evidence of tuberculous disease. Nevertheless, ascitic fluid found in the vicinity and inoculated into guinea-pigs may cause tuberculosis. From these observations, Dr. JAMES concludes that there is a latent form of tuberculous peritonitis, and that the condition may not give rise to any symptoms of disease. It is noteworthy that the condition was observed in young patients who had suffered from bone or joint tuberculosis, for it is in patients of this type that latent pulmonary tuberculosis is sometimes discovered on X ray examination of the chest. Thus we cannot assume that latent abdominal tuberculosis is a common condition, or that it is apt to occur in children who are not suffering from any recognisable form of tuberculosis in other organs.

NERVOUS DISABLEMENT IN WAR AND INDUSTRY

WE may attribute to the late war the enforced recognition of the importance of the minor psychoses and some of the subsequent growth of interest in their study and treatment. The recent conference of the Ex-Services Welfare Society, which deals solely with ex-Service officers and men suffering from neurological and mental trouble, gives evidence that the original stimulus is still, unfortunately, continuing; for the official subject of discussion was the persisting effect of war neuroses. The conference was concerned not only with men recognised originally as suffering from war stress, but with the late development of disability in those who had not applied for pension until they were finally beaten after years of struggle. It is in such cases that the Society is able to give help that the Ministry of Pensions cannot give. But the Society can do more than that. During and after the war the Ministry not only established clinics but trained already qualified men for service in them; they provided hospitals for those that needed them and freely gave grants and facilities for training to nervously disabled pensioners. The one thing beyond their power was to give continued support to the men in the social and economic struggle, and here the Welfare Society finds its special task. At the conference repeated reference was made to economic difficulties and civil stress, and the hostels and sheltered industries maintained by the Society have been called into being because the essential need of these men is opportunity to work without the combination of uncertainties and rigid demands found in ordinary industrial life. This need is definite, whatever may be thought of the causation or attributability of the men's troubles; without help such as the Society provides, the outlook for many sufferers would be hopeless.

An article by Dr. AUBREY LEWIS in our present issue, on neurosis and unemployment, is concerned with an almost identical problem which, as he shows, calls for similar handling. Whether unemployment produces psychoneurotic trouble is an obvious question; but Dr. LEWIS does not attempt to answer it. His investigations consisted of a detailed examination of the clinical findings, and the occupational and family history, of 52 men referred to a clinic by local public assistance committees because of presumptive mental disorder. All were on out-relief and in the histories there was often abundant evidence of the previous existence of neurosis and, indeed, of a tendency to seek the refuge of pension or compensation. At the same time, out of 38 men to whom this observation applied, 26 gave satisfactory work records or, in other words, had shown themselves at one time to be efficient members of the social organisation. This should be linked with the findings of Industrial Health Research Board investigators that severe psychoneurotic symptoms may exist without producing industrial disability; that is, we may suppose, so long as working conditions are satisfactory to the individual.

Dr. LEWIS concludes that these cases are as much social as medical problems and advocates psychotherapy together with measures which, as he points out, are identical with those already carried out by the Ministry of Pensions and the Welfare Society. He remarks that, as far as psychopathology is concerned, there is nothing to distinguish these men from patients in other walks of life who show *similar* symptoms, but in their reactions there appears a general attitude of touchiness and resentment that brings them into line with the chronic "compensation or pension-neurosis." We agree that prophylaxis of these disorders must wait on better knowledge, but the development of this unfortunate state of mind clearly deserves more attention than it has hitherto received. Condemnation there has been in plenty; for few writers adopt towards it the objectivity successfully maintained by Dr. LEWIS. Whoever has studied the victims of compensation-neurosis, whether following accidents or in the occupational neuroses, finds among them men, previously decent citizens, who seem to have as their only object the clinging to compensation. In some of them the elements producing that mental attitude can be elucidated. Genuinely incapacitated by nervous symptoms, the man receives little or no skilled help; the symptoms develop unhindered even if he fights against them, and the prospect of again being fit to take up his work begins to recede. It is no one's business to find him work within his power, which is a necessity for his recovery (this situation has long been recognised in miners' nystagmus, the man finding no alternative between going back to work down the pit or drawing compensation). Without understanding of his own condition—the first requisite for successful psychotherapy—he must accept the alternative of compensation and bend all his energies towards retaining it. If to this hypothetical story we add that the nervous sufferer does not thus reason out his behaviour, but reacts intuitively and emotionally to the situation, we can understand the evolution of the compensation-neurosis in a previously self-respecting and hard-working man. Whatever views we may hold about the fundamental causes of the minor psychoses, the miserable victim of the compensation-neurosis is a social product; among the other admirable work of the Ex-Service Welfare Society and the psychiatric clinics now being established we see these cases at last receiving that attention and understanding that has for so long been lacking.

AN INDEX OF BLOOD REGENERATION

An important stage in the development of each science is the period when man is just able to give exact quantitative expression to the phenomena he is studying. In the past ten years MINOT and his fellow-workers have not only given us a cure for pernicious anæmia and so stimulated an enormous amount of fundamental work on the ætiology and treatment of blood diseases, but they have also given us a method of accurately estimating the degree of hæmopoietic activity and response to therapy—a method which has lent significance to so much recent work on the anæmias. With our issue to-day we publish a supplement by MINOT and CASTLE in which they discuss the exact principles underlying the methods they have perfected for assessing erythropoietic activity by means of the reticulocyte response.

In order to understand these methods it is necessary to recall the relation of the reticulocyte to the mature red cells. In the blood stream of the healthy adult the majority of the red cells are mature. The young nucleated cells (normoblasts) of the marrow are not found, but a small percentage of cells may show a bluish network or reticulum when stained with brilliant cresyl-blue. These cells, because of their appearance, are known as reticulocytes and are young cells intermediate between the normoblast and the mature red cell. Under suitable experimental conditions their development into mature red cells, through stages in which the amount of reticulum gradually decreases, can be demonstrated in vitro. The reticulum is derived from the basophil substance present in the cytoplasm of young nucleated red cells and is not a nuclear remnant. In ordinary films such cells appear as polychromasic red cells, or cells showing punctate basophilia. Increased erythropoietic activity in the bone-marrow from any cause is made apparent in the peripheral blood by an increase in the number of reticulocytes. If activity is great even younger cells of both red and white cell series will appear. The character of the peripheral blood is indeed an extraordinarily accurate mirror of the character of the bone-marrow. When reticulocytes only are found in excess it is usually safe to assume that erythropoiesis is proceeding in a normal way, though at an increased rate; if normoblasts are found there is clearly a greater increase in rate of development, though presumably erythroblastosis is still of a normal type. If even more primitive cells, as primary erythroblasts, predominate, a grossly abnorm type of red cell delivery is in progress. Wh leucopoiesis is primarily disturbed, as in t leukæmias, the immature white cells afford index of marrow activity. As far as erythropoie is concerned it has been shown by MINOT and othe that a careful quantitative estimation of the p centage of reticulocytes appearing in the peripher blood gives an accurate measure of erythropoie activity. In anæmia with an aplastic marro few, if any, reticulocytes are found. In anæm with an active marrow, as in acholuric jaundic there is a high output of these cells. In t dyshæmatopoietic anæmias, for instance, pe nicious anæmia or leucoerythroblastic anæmi when marrow activity is arrested, the numb of reticulocytes is variable. It is, howeve as an index of the effectiveness of any for of treatment that the reticulocyte count ha proved of greatest value, for if no interferin factors are present and sufficient quantities appropriate potent material are given, the outpu of reticulocytes in any patient is strictly relate to the initial number of red cells and hæmoglobi and can therefore be used as an extremely accura measure of the efficacy of any therapeutic procedur

The fact that the principles underlying th interpretation of reticulocyte reactions must b carefully understood, and certain precautions observed if full use is to be made of the informatio they provide, is emphasised by MINOT and CASTL The reactions should be of special value in estimating the potency of different commercial preparations. An important practical point emerge here, namely, that the description of any commercial product should indicate what dail amount is just sufficient to produce a maxima reticulocyte response, which is the only accurat measure of potency. At present, the doctor prescribing one of these preparations is told only th original amount of liver or stomach from whic it has been obtained, or the weight in grammes o some constituent—for example, of iron. It i difficult for him to assess the potency of the en product, and it is that alone with which he i concerned. Now that MINOT and CASTLE have added to their previous important discoveries a delicate means of measuring the potency of each member of a whole group of therapeutic remedies, let us hope that it will be speedily put to practical use.

AUSTRALIAN AND NEW ZEALAND ASSOCIATION OF RADIOLOGY.—On May 17th the first annual general meeting of this association was held at Canberra, when Dr. A. T. Nisbet was elected president; Dr. H. M. Hewlett, vice-president; Dr. H. R. Sear, hon. treasurer; Dr. H. M. Cutler, hon. secretary; and Dr. J. G. Edwards, Dr. P. Parkinson, Dr. J. C. Clendinnen, Dr. J. O'Sullivan, Dr. J. S. Verco, Dr. W. Holman, Dr. V. McDowall, Dr. B. L. W. Clarke, Dr. Syme Johnson, and Dr. C. C. Anderson, members of council. The association has been established to promote the advancement and study of radiology and allied sciences and encourage research and experimental work in connexion with those sciences. It is hoped to provide facilities for general conferences and discussions, and supplements to the *Medical Journal of Australia* and the *New Zealand Medical Journal* will be devoted to the work of members.

ANNOTATIONS

NERVE LESIONS AND VITAMIN-A DEFICIENCY

Of late years attention has been directed repeatedly to the possibility that vitamin deficiency is responsible for some forms of degeneration within the central nervous system. In this country E. Mellanby has indicated a probable relationship between vitamin-A deficiency and the so-called toxic degenerations such as ergotism, pellagra, and lathyrism. Extension of this conception to account for the lesions of subacute combined degeneration and disseminated sclerosis has on the whole found less support, although the evidence for such a relationship is suggestive enough to encourage further inquiry along this line. The recent publication [1] of further experimental work by Prof. Mellanby emphasises the importance of the part played by vitamin A in maintaining the integrity of the nervous system especially in young animals. Rabbits of 8–10 weeks old were used in his experiments, and he has found that widespread degeneration of the myelin sheaths in both peripheral and central parts of the nervous system follows the maintenance of these animals on a diet deficient in carotene and vitamin A. Clinically there is stiffness of the limbs, especially of the hind legs, after 2–3 months of this diet and later still xerophthalmia and head movements are observed. Histologically the afferent paths of the nervous system are most affected—namely, the spino-cerebellar and spinoreticulothalamic tracts, the posterior columns of the spinal cord and the afferent fibres in both cranial and spinal nerve-roots, excluding, however, such fibres in the vagus nerve. Slight degenerations may develop in the efferent pathways at the same time, but these seem to be exceptional. Mellanby also describes degenerative changes in the neurones on the sensory side but finds it impossible to say whether neurone or fibre is primarily affected.

Although the histological descriptions are based entirely on Marchi preparations (as far as myelin sheath degenerations are concerned), there can be little doubt of the validity of these results in view of the careful controls carried out to eliminate possible confusion with post-mortem artefacts. The importance of the work, which Mellanby describes as being of a preliminary nature, cannot now be assessed. As he says, "the fact that degenerative changes are more easily produced in young animals than in old suggests that these nutritional factors play a large part in determining the structural development of the nervous system, either as a whole or in part, in early life and even in the fœtus. If this is so, it is another instance of the supreme importance of the proper nutrition of the mother during pregnancy and lactation, and of the young child during the development of the nervous system."

PROPHYLAXIS WITH A LIVING PLAGUE VACCINE

At a meeting of the French Academy of Medicine [2] last month Dr. G. Girard, director of the Pasteur Institute of Antananarivo, Madagascar, described further results obtained by the prophylactic use of an attenuated, but living, vaccine of *Bacillus pestis*. Girard and J. Robic had previously brought forward evidence that the living "E.V." strain of *B. pestis* is superior to killed vaccines for preventing plague both in animals and in man. For human beings it had then been used with extreme prudence and without the slightest accident immediate or remote. The further series of inoculations now reported on with this living "E.V." strain of plague were carried out in Madagascar between October, 1934, and May, 1935. A census of the particular district concerned had been made two months previously, and the population (excluding children under two years, who were not vaccinated) was found to be 96,000, of whom 46,879 voluntarily submitted themselves to inoculation. Vaccination centres were established throughout the district, and the vaccine was transported in thermos flasks charged with ice. The reactions to the vaccine were of minor degree and did not prevent the inoculated from continuing their occupations. Afterwards, special care was taken to ascertain the cause of death in the district by bacteriological investigation, and the figures for five months (December to May) are summarised as follows. Among the vaccinated (46,879) the number of deaths from plague was 22, or 0·47 per thousand, and the general mortality 225, or 4·8 per thousand. Among the controls held (these are put at 60,000, which is nearer the true mark than the official census figure of 49,121) there were 100 deaths from plague, or 1·66 per thousand, and the general mortality was 581, or 9·7 per thousand. Girard points out that not only the plague mortality, but also the general mortality was reduced by half among the vaccinated. Septicæmia from *B. pestis* was far less among the vaccinated, and it is emphasised that this is of special importance in a country where *Xenopus cheopis* is widely distributed and capable of transferring the infection. Girard admits that his statistics are in places open to criticism, but maintains that the immunity conferred by the living vaccine, both in animals and man, is evidently superior to that produced by the killed vaccine.

CAN ASCARIS INFECTION BE AIR-BORNE?

In an annotation last year on the prevention of ascaris infection [1] we remarked that, keeping this end in view, controlled experiments were needed on the bore-hole latrine. Since then the suggestion has been put forward [2] that the attraction of this structure for the Indian is likely to be great, seeing that it can be made and used privately close to his own house, and being his own is all the more likely to be kept clean. That is true. But if properly used will it do more good than harm? The bore-hole latrine is a narrow tube, 18 in. across, normally made straight down into the subsoil water, and often with a lining of basket work to prevent its walls from falling in. It has been said that when the tube has reached the subsoil water and is not overworked, fæces will become completely liquid and be lost. But in just such conditions it is well known that this is far from being the end of fæcal bacteria; there may be wide carriage of them by subsoil water, and the suggestion so made becomes in fact one for the deliberate fouling of the usual drink of hundreds of millions of those living in the tropics. Moreover it is wrong to take it as probable that fæces ejected from the anus at the top of a long narrow vertical tube will drop cleanly by gravity into the water at the other end. The fæces of most Indians are normally mushy, and after the passage of a soft stool the bore-hole will be spattered to within a few inches of its top. Moreover the rough holes of the bore or of its lining cannot be cleaned; where fæces have landed, there they must rest. Assuming that there are ascaris eggs within them, the question whether embryos which have formed will or will not become parasites in man depends on factors analysed by Anne McRae[3] and H. W. Brown.[4] There is no hatching of the embryo in the sense in which a chick makes its own way out of the shell, for the burst in the ascaris eggshell is made by physical forces acting from without; thus, while chemicals have little effect, the stirring of ripe eggs in wet sand has set free 80 per cent. of the embryos, and after a long car journey the same thing has happened on a great scale in sand culture. Again, when ascaris eggs are dried, an air bubble is formed within the shell, and when they are next wetted osmosis becomes the cause of a break in all the shells and all the embryos become free. The very rough outer coat of the ascaris egg gives the resistance necessary for air-carriage; with air inside it the dry egg will be lightened; and the arrival of the egg on the moist mucosa of the nose should then bring about "hatching." Doubt as to whether air-carriage does or does not take place could, we suggest, be resolved under experimental conditions by use of the hot air thermal precipitator of Whytlaw-Gray and Lomax, referred to by H. L. Green and H. H. Watson.[5] This filters out from air particles varying from 200 µ across to ultra-microscopic size, and it should demonstrate the presence or absence of ascaris eggs. The question of air-carriage in another worm infection is important for the British Army in India, for Colonel W. P. MacArthur has given strong reasons for the belief that *Cysticercus cellulosæ* is conveyed in this way. The effects of this parasite, however, are too grave for its mode of spread to be tested on man or even (with a quiet mind) by man. Accordingly the possibility that ascaris may be air-borne requests investigation not only for its own importance but also for the knowledge it may give of that by *C. cellulosæ* and perhaps by other worm parasites. Here there is no great danger; and here there is a test animal to hand, the pig, on the mucosa of whose nose dried embryonated eggs can be placed.

POOLED HUMAN MILK

THE use of pooled surplus breast milk for feeding premature infants in institutions, or for young babies with severe alimentary disturbances, is being increasingly advocated in this country; but Prof. W. Catel,[6] director of the university children's clinic in Leipzig, throws doubt on the value of human milk for such purposes after it has undergone the heating which is customary. In view of the difficulty of organising and maintaining a steady supply, and the correspondingly high price which has to be paid, his observations demand full consideration. Having compared the morbidity and mortality among premature infants fed on fresh human milk with the corresponding rates among those fed on similar milk heated for three minutes at 100° in a Soxhlet apparatus, he finds that the latter are definitely at a disadvantage; he particularly comments upon the greater frequency of bowel disturbances among those receiving the heated milk. In another series he finds that the daily gain in weight was 25 per cent. less among infants fed on sterilised human milk than among those fed on fresh breast milk; some of the children indeed did better on a cow's milk mixture of similar caloric value than on either form of breast milk. Catel therefore believes that sterilised human milk has no advantages over a cow's milk mixture for the rearing of "delicate" babies. This is an astonishing conclusion, and the number of cases described in detail in his paper is so small that it is impossible to judge whether it is really justifiable. Logically from his observations Catel argues that from the social standpoint schemes for the collection and distribution of breast milk are not worth while. The surplus milk of healthy mothers, used in a fresh state, he still regards as the optimum diet for premature or delicate infants deprived of their own mother's milk, and he argues for a raising of the status of the wet-nurses commonly employed in German institutions.

SILENT MASTOIDITIS

ACUTE suppurative otitis media may follow any of several courses. After discharging through a natural or artificial opening of the drum membrane, it may, and as a rule fortunately does, subside with healing of the perforation within a period which varies from a few days to several weeks. Alternatively frank and easily recognisable signs of mastoiditis, and sometimes also of intracranial complications, may develop; or the discharge may persist and become chronic without the appearance of obvious mastoiditis. During the first few days tenderness over the mastoid is common, and most otologists agree that the mastoid antrum and cells are usually involved in the inflammation, but tend to recover in the absence of such adverse factors as extreme virulence of infection, lowered resistance, or obstruction of drainage. Definite mastoid disease and intracranial complications are rare in the first week, and many authorities are convinced that the subsequent course of the disease is unsatisfactory when the mastoid has been opened at this early stage. On the other hand, when the discharge from the ear persists undiminished, even in the absence of other symptoms, for more than about three weeks, it is highly probable that there is suppuration in the mastoid. *If nothing* is done the best that can be expected is a permanent perforation [illegible] with its attendant dangers and [illegible] mastoid operation should be undertaken in such cases, and a surprisingly extensive infection will usually be found.

Dr. George D. Wolf,[1] of New York, who deals with these matters under the title of "silent mastoiditis," quotes Koerner's statement that he has always found bone destruction when there is a profuse ear discharge lasting 4–6 weeks, except perhaps when the discharge is diminishing. He does not define the term "silent mastoiditis" with exactness, but cases are certainly common in which the course of the disease may be described as asymptomatic, atypical, or insidious. There is, however, nearly always a discharge from the ear and usually other signs can be found if carefully sought, such as slight occasional rises of temperature, narrowing of the deep meatus, bulging of its postero-superior wall, or tenderness on deep pressure at some spot behind the ear which, at least after the third week, is a definite indication for operation. It occasionally, though very rarely, happens that a mastoid abscess forms when the membrana tympani is intact, having ruptured and quickly healed or never having perforated; such cases naturally cause great difficulty of diagnosis, but there is always a history of earache a few weeks before, the drum is not entirely normal in appearance, and the hearing is somewhat impaired. Apart from such rarities, acute mastoiditis will seldom pass undetected if it be remembered that its development is by no means always accompanied by such obvious signs as severe pain and high fever. The "cortical" mastoid operation is not in itself a dangerous one—Mr. T. B. Layton lately said that from the patient's point of view it is a far smaller operation than the removal of tonsils and adenoids[2]—and nearly always it leaves behind a healed, intact membrane, usually with little or no impairment of hearing. If it were performed in all cases of acute suppurative otitis which show no signs of recovery by the end of the fourth week, a very large proportion of the great mass of chronic aural suppuration would be prevented, a fruitful source of deafness abolished, and the intracranial complications of chronic otorrhœa largely eliminated.

AMBULATORY TREATMENT OF FRACTURES OF THE FEMUR

In cases of fractured femur it is by no means easy to provide support and fixation sufficiently rigid to allow of weight-bearing from the outset. With all his enthusiasm for the unpadded plaster cast and ambulatory treatment in fractures *below* the knee, Böhler[3] nevertheless states that the method of continuous traction is preferred in his clinic for fractures of the femoral shaft. The trouble about fixation with plaster, in these particular fractures, is that the plaster cast does not grip the limb firmly enough to resist the great tendency to deformity at the fracture site—a tendency due mainly to the powerful pull of the thigh muscles, and also (in walking) to the tendency of the upper fragment to "settle down" in the splint. R. A. Griswold,[4] of Louisville, Kentucky, has been so much impressed, however, by the advantages of ambulatory treatment that he has evolved a method—analogous in most particulars to that used in many clinics for fractures of the tibia—by which he believes that ambulatory treatment has been rendered feasible with the assurance of good anatomical and functional results. For such treatment Griswold claims not only the obvious advantage that it shortens the time the patient occupies a bed in hospital, but also that the use of the limb in weight-bearing and walking encourages healing, and helps to maintain muscular strength and normal joint function. Measurement of the circumference of the thigh and calf shows little or no wasting, and, on removal of the cast, as much as 45 degrees of painless movement of the knee-joint may be possible at once.

The principles of Griswold's method may be summarised as follows: The length of the limb is restored by extension; and after the shortening has been corrected, two pins are inserted, one transversely through the distal fragment just above the adductor tubercle, the other in an antero-posterior direction at, or slightly below, the level of the lesser trochanter. By manipulation of these pins, angulation and rotation of the fragments on one another is corrected. The limb, with the correct alignment of the bone-ends restored, and with the pins in situ, is encased in an unpadded plaster cast, which reaches from the xiphoid cartilage to the toes. Walking is permitted as soon as the plaster has hardened. So that the plaster splint may act in the same way as a Thomas's walking calliper—i.e., by counter-pressure on the ischial tuberosity—a roll of padding about 8 inches long, and of the thickness and firmness of a Thomas's splint roll, is placed in situ and incorporated in the plaster. On the perineal side of the thigh the plaster is so modelled as to hold the pad in position and to form a shelf against which the body-weight can be partly supported.

To certain points Griswold draws particular attention. The pins, for example, are not used at all for extension, the correct length being restored before their insertion; and they are thus free for manipulation. By experience, the importance of the proximal pin has been demonstrated. At first a pin was used to correct the posterior angulation of the *distal* fragment of fractures of the lower third of the femur, trusting to the ischial pad to prevent "settling down" of the upper fragment in the plaster case. This plan, however, proved unreliable, and use of the upper pin was adopted. For manipulation and support of the pins, special mechanical arms are attached to the table on which the patient lies for reduction and fixation of the fracture. The properly constructed plaster cast for an adult should weigh about 12–14 pounds. Five patients treated by this method walked on the second to the eighth days following injury; in another 5 cases the same fixation was applied, but on account of other fractures (2 cases), psychosis (2 cases) and transfer to another hospital (1 case), ambulatory treatment was not adopted. The results have been very satisfactory; and for straightforward fractures, without complication, the stay in hospital has been reduced to an average of twelve days.

SENSITISATION TO LIGHT

It is not surprising that so vital an influence as light should find its way into many chapters in the book of medicine. In the fourteenth century John of Gaddesden used red light to diminish the ravages of small-pox in the skin, and there are still practitioners who believe in the efficacy of coloured beams. Comparatively recently Finsen extended light therapy into the invisible regions of the spectrum, and to-day ultra-violet and other forms of irradiation are very widely used. Much remains obscure, however, in the mechanisms by which these remedies do their work. A fact which has a bearing on their action is that the presence of certain dyes and fluorescent substances in the blood stream is capable of sensitising the subject to light—a discovery which was once tentatively applied in connexion with the Finsen treatment of light. The observation that hæmatoporphyrinæmia is associated with hydroa vacciniforme has pointed the way to an explanation of the wide range of diseases (both in man and in animals) which are due to light irritation or which show light-sensitiveness as a characteristic symptom; summer prurigo and actinic dermatitis, lupus erythematosus, and pellagra are examples. In reviewing this interesting subject Dr. Eidinow[1] describes some original work which he has done using eosin, erythrosin, fluorescin, and rose-bengal as light sensitisers. He finds that after these preparations have been injected into the blood stream or the tissues infra-red or luminous rays produce effects comparable with those of ultra-violet irradiation. Thus hæmolysis of red cells suspended in saline, a lethal effect upon infusoria and a raising of the bactericidal power of the blood follow exposure to luminous rays when sensitisers are present. These are, however, not effective when painted on the skin and they are excreted within a few hours of being injected. This work suggests a possible field of therapeutic research, and Eidinow claims to have had some success in the treatment of lupus and chronic ulcers among other conditions, by the local injection of sensitisers and subsequent exposure to infra-red and luminous radiations.

IN MEMORY OF HUGHLINGS JACKSON

AMONG the tributes to Hughlings Jackson in this centenary year, those of foreigners have a special place. Elsewhere in this issue will be found an account of the commemorative address in which Prof. Otfrid Foerster spoke of the prescient genius of the greatest of English neurologists. At the International Neurological Congress, Prof. Otto Sittig, of Czechoslovakia, who has done much, by translation and exposition, to make Hughlings Jackson's writings accessible abroad, pointed out how he had anticipated modern views about consciousness. From Hungary comes an impressive memorial volume[1] in which the published writings from the *Stephen Tisza University in Debreçen* are collected and dedicated to Hughlings Jackson, with an appreciatory biographical foreword by Prof. Benedek, the director of the clinic in mental and nervous diseases there and editor of the volume. The papers cover a wide range of topics in neurology and psychiatry, some of them in fields unexplored until recent years. One of the most interesting contributions is a monograph by Prof. Benedek concerning the effects of insulin shock therapy on perception. Insulin had been used in his clinic for several years as a means of combating the disinclination for food in negativistic schizophrenic patients; later it was employed to produce hypoglycæmic shock in schizophrenia, and to a less extent in confusional syndromes. In the patients so treated special disturbances occurred in the perception of forms, space, and movement. The experimental production of psychopathological phenomena by drugs is a field much cultivated of late years; by it our knowledge of the functional capacities and responses of the brain is being enlarged. Other papers, here included, indicate the mutual dependence of neurology and psychiatry, and their common use of the principles so brilliantly divined and laid down by Hughlings Jackson.

MEDICAL RESEARCH IN SHANGHAI

IN his introduction to the report of the first full working year of the Henry Lester Institute of Medical Research in Shanghai, the director, Dr. H. G. Earle, briefly discusses the principles which guide the work of the Institute as a whole, and which have persuaded him to organise the division of medical research into three categories—clinical, physiological, and pathological. In the division of clinical research, interest has been centred upon diseases with a definite nutritional basis or which lend themselves to biochemical investigation on the clinical side. On the surgical side peptic ulcer, appendicitis, and urinary infections are being investigated, supplemented by experimental work into the underlying physiological and pathological processes. In the division of physiological sciences, Chinese diets and foodstuffs have been analysed in regard to vitamin and mineral content. Chinese drug terminology is being studied as it applies to modern medicine, as well as the toxic effects of chaulmoogra salts upon the liver and the reputed diuretic and antipyretic properties of Chinese perilla. In the division of pathological sciences, typhoid, cholera, the bionomics of the mosquito, and the natural history of schistosomiasis—all of which have a water factor—receive attention. A comprehensive study has been made of the distribution of blood groups among the Chinese population in Shanghai, and the material of the associated Lester Hospital permitted the study of blood tests for syphilis—e.g., the influence of high and low temperatures upon flocculation. But the chief interest of the report lies in the important investigations carried out by the department of epidemiology and medical statistics, a section under the immediate supervision of the director. A wide-scale hospital survey—one of the greatest voluntary collective investigations so far attempted—has provided valuable and fundamental data relating to disease-incidence in various parts of China. Hospital populations are usually regarded as providing but a poor index of disease-incidence by reason of the selective factor, but in China, hospitals perform in high degree the duties usually undertaken by general practitioners in other countries, and in this survey a uniform method has been adopted of collecting and classifying data for in- and out-patients treated in scattered hospitals. The survey has stimulated a spirit of inquiry and investigation among many medical workers; it has shown what are the clinical problems with which hospitals have to contend, and had already increased the general stock of knowledge about incidence and distribution of disease in China. Though this work has been discontinued so far as the Institute is concerned — although the machinery is being used in the other divisions—the *National Health Administration of China* will continue a modified survey on the same lines. The Institute is devoting much effort to popularising research through the medium of public lectures and demonstrations; during the session 1933–34 something like 50 lectures and demonstrations were given in the theatre of the Institute, many of them being illustrated by photographic and cinematographic records produced in its laboratory. These are some examples of what is being done by a well-staffed and liberally equipped institution. Copies of the report, and of papers published by members of the staff, are available on application to the registrar, Lester Institute of Medical Research, Avenue Road, Shanghai, China.

THE ONION AS A SOCIAL PROBLEM

IN the laboratory of applied physiology at Yale University, H. W. Haggard and L. A. Greenberg[1] have been trying to find why an alliaceous odour persists in the breath after eating onions or garlic. It is generally supposed that, like ether, alcohol, and acetone, the essential oil of onion passes into the blood stream and is aerated from the blood in the lungs, so passing into the expired air. Alternative possibilities are that these oils are secreted into the saliva or that the smell comes from the stomach by way of the œsophagus. Haggard and Greenberg will have none of these hypotheses, and they seem to produce conclusive evidence in favour of their own explanation. Their initial experiment was to give 1·5 g. of raw garlic, chewed and swallowed in the ordinary way and followed by the usual odours for a day or more. The same person then took the same quantity chopped in small particles but enclosed in gelatin capsules. No smell whatever was detected in the breath, except once when the subject belched three hours after taking his dose. The investigators thence passed to quantitative tests, where we need not follow them. But all the results go to show that they are right in thinking that the continuing smell of onions or garlic in the breath arises solely from particles retained in the mouth. These particles cannot be completely removed by mechanical means: to brush the teeth and tongue, to wash the mouth with soap and water or even with a 30 per cent. solution of alcohol, will not deodorise the breath. Haggard and Greenberg however are able to propose a remedy which is in fact effective—namely, the rinsing of the mouth with a solution of chloramine, which liberates free chlorine in the mouth and so quickly and completely removes the offending odour. They suggest that many cases of foul breath from other local causes are probably amenable to the same simple treatment, and we hope this may be so. It is salutary, however, to remember the story of the American millionaire who, stimulated by advertisements, spent a large sum on a cure for halitosis; only to find afterwards that his friends did not like him anyway.

A BASE-LINE FOR ASTHMA TREATMENT

For asthma there are many remedies but no fundamental cure. While the first task of an asthma research clinic should be to investigate the cause and the mechanism of the disease, it can scarcely avoid an attempt, at once, to assess empirically the value of some well-known therapeutic measures. Since none of these is strikingly and regularly effective, and since the disease is variable in severity and erratic in course, this can be done only from the records of large series of cases adequately controlled. Such a study is under way at the Guy's Hospital asthma clinic, two workers [1] from which have just published, by itself, their series of controls. The group consists of 127 asthmatic out-patients treated by the ordinary general measures—namely, the removal of the most obvious allergens like feathers and orris root, and the prescription of the indispensable ephedrine and adrenaline—together with a weekly subcutaneous injection of normal saline. *On this régime* of hygiene, symptomatic remedies, and deception half of them lost or nearly lost their asthma for two months. In a further four months a quarter of these had relapsed. The experiment was to be continued for a year, but the results at the end of the second six months are not given. When complete the observations will form a useful yardstick with which to measure the value of such things as vaccines, protein injections, and—possibly the coming favourite—gold. As they stand, they throw into relief the frequency of temporary improvement in the asthmatic after a visit to a new doctor who shows a special interest in him. This phenomenon is familiar to all who treat such patients. It is easily interpreted as the effect of a new remedy but in fact it is usually no more than evidence that "mind and morale play so large a part in asthma."

ACROSS THE FRONTIERS

Many workers in science, and especially in medicine, get an additional satisfaction from their profession because it is super-national. The pursuit of knowledge and the relief of pain are forms of endeavour containing the germ of a world order: they advance coöperation instead of hindering it, and they make the need for it gradually plainer to all. The past few years have led many men and women in many countries to make sacrifices for their faith in institutions beyond those countries. By mitigating the hardships these people have suffered we can if we wish show belief in the unity of the scientific world; and we have ready means of doing so by support of the Academic Assistance Council established in this country "for the relief of suffering and the defence of learning and science." Under the presidency of Lord Rutherford that council has pursued for more than two years its attempt to help university teachers and investigators displaced on grounds of religion, political opinion, or race, and the successful use of its resources is apparent in the second annual report just issued.[1] These resources remain regrettably slight, and the Council has depended, and still depends, on small subscriptions. Such subscriptions however pull more than their financial weight, since their number "demonstrates general support for the principles of university freedom which the work of academic assistance attempts to defend."

THE ACTION OF TETANUS TOXIN

In a leading article last week we stated the current belief that the toxin of tetanus enters the central nervous system through peripheral nerve-endings and travels up the axons of the motor nerves. But according to Abel, Hampil, and Jonas,[2] of Johns Hopkins University, this belief is no longer tenable. At present it is generally supposed that voluntary muscles cannot be tetanised until the toxin has been conveyed by the nerves to the anterior horn cells of the spinal cord; when these cells have absorbed the toxin they pass into an over-excitable state and respond more vigorously to kinæsthetic and other sensory impulses, so that a steady stream of motor impulses to the respective muscles keeps them in a state of tonic rigidity. The Baltimore investigators now show that the toxin can be injected in doses of 1/50 to 1/17 of a lethal dose into the trunk of the sciatic nerve of a dog without exerting any action, either local or central, while even larger quantities can be injected intravenously without effect. If the toxin is injected directly into muscles, on the other hand, amounts as small as 1/200 m.l.d. will suffice to tetanise them; and from these and other observations Abel and his colleagues deduce that tetanus toxin has a very powerful direct and specific action on voluntary muscles whose motor nerve terminals are intact—this action being strictly peripheral, like that of curare. They rightly point out that certain well-established facts appear to stand in the way of this theory. For example, when the nerves of a tetanised limb are transected its muscles will relax immediately and completely if they have not been in a state of increased tone for more than a few days; conversely, the muscles of a limb whose nerves have all been completely transected cannot be tetanised to the slightest degree by injecting them with an amount of toxin that will cause the muscles of a sound leg to become completely rigid and remain so for weeks and months. These objections, the investigators think, cannot be sustained in the light of the newer methods which they have used in nerve transection experiments. But for details of these further experiments we are obliged to wait until later papers are published.

RE-ESTABLISHMENT OF A FRACTURE CLINIC

THE governors of Guy's Hospital have decided to re-establish the fracture clinic there. At the present time cases of fracture are dealt with in various departments: a small proportion goes to the orthopædic department, a few which require open operation are treated by the general surgeons, the remainder falls to the care of the two operating registrars. After-care is a matter for the house-surgeons of the four surgical firms. Under the new arrangement all ambulant cases will be treated at the fracture clinic which will have a permanent junior staff consisting of orthopædic registrar, surgical registrar, orthopædic house-surgeon, and sister in charge of the massage department. Two meetings will be held each week, attended alternately by the senior assistant surgeon and the orthopædic surgeon, who will take charge of the cases attending on their own days. On the third day the surgical registrar will deal with urgent cases to be transferred later to the surgeon sitting at the next clinic. Cases requiring admission will be taken into the hospital under the surgeon of the week; on their discharge they will attend the fracture clinic unless the surgeon under whose care they have been in hospital wishes to continue his supervision. It is a defect of the scheme that the surgeon in charge of the clinic has nothing to do with the care of fractures in the wards, and it may be hoped that this will come later. In the meantime the arrangements for after-care with provision for graduated work will help to shorten the period of incapacity, of which the systematic follow-up will afford a measure of control.

LYDIA RABINOWITSCH

THE death of Frau Lydia Rabinowitsch-Kempner at her home in Berlin at the age of 63 removes one of the few remaining links with Robert Koch, in whose laboratory she did her early researches on the tubercle bacillus and allied organisms. The daughter of a Jewish merchant, she was born at Kovno, and received her early medical training in Zurich and Berne, going on to lecture at the women's medical college in Philadelphia in the winter and to work in Koch's laboratories in the summer. Her first published work (1897) was on a saprophytic acid-fast bacillus which she found in 60 per cent. of samples of butter taken in Berlin. She then turned her attention to tuberculosis in animals, and published a series of investigations, some of them in conjunction with M. Koch, carried out in the Berlin zoological gardens. This work included some of the earliest work on the avian strain of tubercle bacillus, on spontaneous tuberculosis in wild animals, on hereditary transmission through the eggs of birds, and on Johne's disease. She became editor of the *Zeitschrift für Tuberkulose*, which has stood in the forefront of German research on this subject for many years. One of her last contributions to tuberculosis research was (1927) a typically careful record of work done on the filtrable virus of the tubercle bacillus. But tuberculosis was not the only subject on which she worked with success. When Robert Koch returned from Africa she worked on the trypanosomes under his direction, and in 1902 she went to study the plague epidemic in Odessa with Walter Kempner, another of Koch's assistants, whom she had married four years before. On Koch's death she went to work under Orth at the Pathological Institute, and continued there until her appointment as director of the bacteriological department of the municipal hospital in Berlin-Moabit. Lydia Rabinowitsch will be remembered not only as a pioneer of bacteriology and one of the ablest of Koch's assistants, but as one of the first women bacteriologists. This was recognised by the conferment on her in 1912 of the title of professor.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. W. J. Colborne to *Rodney*; T. N. D'Arcy to *President* for course; T. Madill to *Orion*; and C. N. Ratcliffe to *Pembroke* for R.N. Hospital, Chatham.

Surg. Lt.-Comdrs. H. G. Wells to *Drake* for R.N.B.; A. C. Paterson and E. J. Mockler to *Pembroke* for R.N.B.; and R. Russell to *Dryad*.

Surg. Lts. W. M. Greer to *Galatea* and F. M. Duthie to Woolwich.

ROYAL NAVAL VOLUNTEER RESERVE

Proby. Surg. Lt. E. J. S. Woolley to *Ramillies*.

Mr. W. H. Green, of Dartmouth, has been appointed Admiralty Surgeon and Agent for Dartmouth. The following appointments as Admiralty Surgeon and Agent have been approved, to date July 24th: Mr. L. P. L. Firman-Edwards, Ryde; Mr. H. S. Taylor-Young, Salisbury; Mr. R. M. Gordon, Witham, Essex; Mr. R. F. Winckworth, Taunton; and Mr. J. H. Harley Gough, Chichester.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. H. V. Stanley, M.B.E., M.C., retires on ret. pay.

Maj. & Bt. Lt.-Col. W. K. Morrison, D.S.O., to be Lt.-Col.

Maj. E. Percival, D.S.O., M.C., to be Lt.-Col.

SUPPLEMENTARY RESERVE OF OFFICERS

Lt. F. H. Williams to be Capt.

TERRITORIAL ARMY

Capts. A. M. Robertson and E. W. Ashworth to be Majs.

G. Garrett (late Offr. Cadet, Liverpool Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Maj. W. Simpson, from Active List, to be Maj.

ROYAL AIR FORCE

Wing Comdr. J. M. Aloysius Costello, M.C., is placed on the retired list.

Squadron Leader H. McW. Daniel to No. 101 (B) Squadron, Bicester, for duty as medical officer.

INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: E. Cotter and J. M. Shah, M.B.E.

Lts. to be Capts.: J. Edis-Myers, T. K. White, R. de Soldenhoff, C. J. Hassett, R. R. Prosser, E. Parry, W. G. Kennedy, and P. I. Franks.

B. F. B. Russell (substituted for the notifns. in the Gazettes of Jan. 25th and March 15th, 1935).

The undermentioned officers retire: Lt.-Col. V. B. Green-Armytage and Lt.-Col. H. Hingston.

INDEX TO "THE LANCET," VOL. I., 1935

THE Index and Title-page of Vol. I., 1935, which was completed with the issue of June 29th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

SUPPLEMENT TO THE LANCET

THE
INTERPRETATION OF RETICULOCYTE REACTIONS

THEIR VALUE IN DETERMINING THE POTENCY OF THERAPEUTIC MATERIALS, ESPECIALLY IN PERNICIOUS ANÆMIA

By GEORGE R. MINOT, M.D., S.D., F.R.C.P.E.
PROFESSOR OF MEDICINE, HARVARD MEDICAL SCHOOL; AND
W. B. CASTLE, M.D., M.S.
ASSOCIATE PROFESSOR OF MEDICINE, HARVARD MEDICAL SCHOOL

(From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston, Mass.)

Introduction

In the blood stream of normal man very few of the red blood-cells present evidence of immaturity. Although the nucleated red blood-cells of the bone-marrow are never seen, except occasionally in the first few days of life, a small percentage (not over 1 per cent. in adults) of the circulating cells show a bluish network when brilliant cresyl blue is used as a vital dye. The appearance of this precipitated material has earned for such cells the name of "reticulocytes."

With markedly increased bone-marrow activity a few nucleated red blood-cells may appear in the peripheral blood. The leucocytes and blood-platelets may also be increased, with a shift towards an immature formula for the leucocytes. Under these circumstances the number of reticulocytes in circulation is invariably increased. When blood production is only slightly augmented, however, reticulocytes may appear in the blood stream without being accompanied by nucleated red blood-cells. In chronic hæmolytic anæmias increased blood production with increased numbers of reticulocytes may be present over many weeks or even a lifetime. In anæmia due to acute blood loss an orderly rise of reticulocytes in the circulating blood begins, reaches a maximum, and ends within a few days after the hæmorrhage. On the other hand, even with severe anæmia due to diminished blood production in the bone-marrow, the reticulocytes may be no more numerous than normal. If, however, the cause of the diminished bone-marrow activity is removed, there may be a pronounced temporary rise of reticulocytes as the bone-marrow is permitted to respond to the existing anæmia. In pernicious anæmia in relapse, as a result of liver or allied therapy, a similar increase of reticulocytes in the circulation is observed, associated with progressive maturation of the immature cells of the bone-marrow. The general characteristics of the response of the reticulocytes under these circumstances resemble those of the recovery from acute blood loss, in which condition also there is a demonstrable increase in the activity of the blood-forming tissue.

These facts, taken with other evidence, make it clear that the reticulocyte is not a degenerating form but is a stage in the development of the red cell intermediate between the nucleated and the fully adult type. The natural or induced fluctuations of the numbers of these cells in the peripheral blood stream have been used as a satisfactory measure of the activity of the bone-marrow or as a criterion of the effectiveness of certain therapeutic agents in anæmia. The description and interpretation of these so-called reticulocyte responses with particular reference to pernicious anæmia is the object of this communication.

Types of Reticulocyte Response

The rate of blood production in the normal individual is probably regulated by the oxygen tension in the bone-marrow. In the normal individual reticulocytes in increased numbers appear in the blood stream as a result of bone-marrow anoxæmia whether due to high altitudes, chronic carbon monoxide poisoning, or deficient, pulmonary gas exchange. In various types of anæmia the reticulocyte response, whether to acute hæmorrhage, increased red cell destruction, the removal of toxic inhibition of the bone-marrow, or the administration of certain substances in the nutritional deficiency anæmias, is in reality a physiological response to the lowered oxygen tension produced by the anæmia. Liver extract, iron, or, for example, vitamin C, although specifically effective in certain anæmias, do not produce reticulocyte responses in normal individuals or in types of anæmia in which there is no lack of such substances available within the body. Thus, these substances do not act as stimuli to the bone-marrow in the strict sense, but merely permit increased or normal maturation of the red blood-cells. The real stimulus in each instance is the diminished oxygen tension produced by the anæmia.

An increase of the number of reticulocytes in the peripheral blood stream does not, however, necessarily mean an increased delivery of red blood-cells by normal physiological processes from the bone-marrow. Thus, for example, in the progressive anæmia of metastatic carcinoma, of miliary tuberculosis of the bone-marrow, or of leukæmia, the presence of the abnormal cells either acts as an "irritant" to the erythroblastic tissue or else the gross amount of this tissue is so much reduced by invasion that despite the increased activity of the remaining erythroblastic tissue, indicated by increased numbers of nucleated and reticulated erythrocytes in the peripheral blood, the total number of erythrocytes produced is less than normal. The effect of splenectomy in increasing the number of immature cells, including reticulocytes, in the circulation is a variable and not well-explained phenomenon. In any type of anæmia, especially in the "crises" of hæmolytic anæmias in which the bone-marrow is active, continued reticulocytosis or a sudden increase of these cells does not necessarily herald a significant increase of the total red blood-cell count. If an increased degree of blood destruction or a sudden hæmorrhage occurs, the increased activity of the bone-marrow may be insufficient to make up the deficit of blood.

Moreover, it does not necessarily follow that a reticulocyte response to the administration of certain substances is an index of orderly and progressive physiological activity such as occurs after liver extract or iron therapy in certain anæmias due, respectively, to deficiency of one or the other substance. The administration of many substances, especially by the parenteral route, may lead to an outpouring of reticulocytes and even of nucleated red blood-cells. In general such reactions are erratic and do not usually conform in amount or in time to the characteristic responses resulting from the replacement of a specific nutritional defect. Thus, in the past, foreign proteins, nuclein derivatives, or crude extracts of various tissues, when given by injection, have been claimed to possess specific hæmatopoietic powers because of the subsequent appearance of nucleated erythrocytes or other immature cells and increased numbers of erythrocytes in the peripheral blood stream of normal animals or man. The fact that such responses occur in normal animals or man clearly differentiates the action of such substances from that of liver extract or iron, both of which are effective *only* in anæmias due in whole or in part to their lack. The fact, however, that liver extract given to patients with atypical anæmias or leukæmias, especially by injection, sometimes causes a reticulocytosis, does not exclude the possibility either of an associated deficiency of the substance effective in pernicious anæmia or of a non-specific response to other substances in the relatively crude sources of active material at present available. It is certainly not necessary to conclude that the principle active in pernicious anæmia is producing the effect in some novel fashion.

Potassium arsenite (Fowler's solution) serves as an excellent illustration of a substance which can produce non-specific reticulocyte responses in man. Its oral administration in sufficient quantity will produce such effects in normal individuals, in myelogenous leukæmia, and in pernicious anæmia.[1 2] Moreover, potassium arsenite will depress the leucocytes in myelogenous leukæmia[3] and in normal individuals, and depress the red blood-cell in polycythæmia vera.[4] In pernicious anæmia the reticulocyte responses to the daily administration of potassium arsenite differ in character from those caused by liver extract therapy in that there is not usually a smooth increase and decline in the number of circulating erythrocytes within a period of a few days. Instead, the maximum value of the reticulocytes may be irregularly maintained for several weeks and the total duration of the reaction may be even longer. In further contrast to the specific replacement therapy, there is not an orderly progressive alteration of the age of the reticulocytes towards more mature forms as the days go by. Instead, the number of distinctly young reticulocytes continues to be approximately the same and may be accompanied by showers of nucleated red blood-cells. Moreover, despite this apparent furious activity of the bone-marrow the total red blood-cell count may not rise appreciably or may rise only after a delay of from two to four weeks. By giving as much as 150 minims of Fowler's solution within two days, however, it is possible to contrive a reticulocyte response that resembles rather closely that produced by liver extract in pernicious anæmia. It is possible, however, to show that in pernicious anæmia at the end of many days of elevated numbers of reticulocytes as the result of the administration of potassium arsenite, a complete and typical reticulocyte response to liver extract may be obtained as soon as the reticulocyte response to the arsenic has subsided[2] (see Fig. 1).

It is difficult, therefore, to believe that the action of liver extract and that of potassium arsenite are identical. Since it is even more difficult to believe that pernicious anæmia is a disease due to a deficiency of arsenic, it is evident that the reticulocyte response alone cannot be utilised uncritically as a test of specific physiological activity. Particularly with parenterally administered substances are non-specific effects of various sorts likely to be exhibited. Our own experience has been that preparations containing protein derivatives and known to be inert when orally administered in pernicious anæmia may upon parenteral administration produce reticulocyte responses in certain patients and little or no response in others. The effects originally reported by Morris and his associates[5] from the injection of concentrated gastric juice and more recently analysed by Fouts, Helmer, and Zerfas,[6] very possibly illustrate the same principle. The reticulocyte responses and increases of red blood-cells observed were decidedly more variable in their character and time of onset than would be expected from the parenteral injection of liver extract. In contrast to these phenomena, the reticulocyte responses induced by an acute hæmorrhage in normal man or, for example, by liver extract in pernicious anæmia indicate by their regularity and typical characteristics the physiological activity of the bone-marrow. In each instance if the cause of the anæmia is not re-established respectively by further bleeding or by lapse of the supply of liver extract, the patient's blood becomes and remains normal.

Characteristics of the Reticulocyte Reaction

Reticulocyte responses to the administration of specific substances have been observed in anæmias due to deficiency of liver extract,[7 8 9] iron,[10] and vitamin C.[11] The first of these conditions has received the largest amount of study. The reticulocyte responses in Addisonian pernicious anæmia will be especially discussed below. Subsequent references to liver extract refer to preparations possessing in common with desiccated stomach an effect in pernicious and certain other macrocytic anæmias and not in iron-deficiency anæmias. In addition of course whole liver contains other substances, for example, those effective in hypochromic anæmia (iron and "secondary anæmia" fraction), and in the anæmia of scurvy (vitamin C). The features of the reticulocyte reaction when observed under controlled circumstances are sufficiently uniform to justify certain generalisations. In this communication the percentage, and not the absolute number of reticulocytes in the peripheral blood, will be used as the basis of the discussion. By reference to the total red blood-cell count, the absolute number of reticulocytes can always be calculated. In the interpretation of the reticulocyte responses several factors must be evaluated on the basis of daily reticulocyte counts and frequent determinations of the red blood-cell level.

There are certain general features of the reticulocyte reaction in pernicious anæmia which obtain, whether the active material is given orally or parenterally, in a single large dose or in small uniform daily dosage, provided the amount of material given is sufficient to produce a significant increase of reticulocytes. Almost always within a period of from two to ten days the percentage of the reticulocytes in the

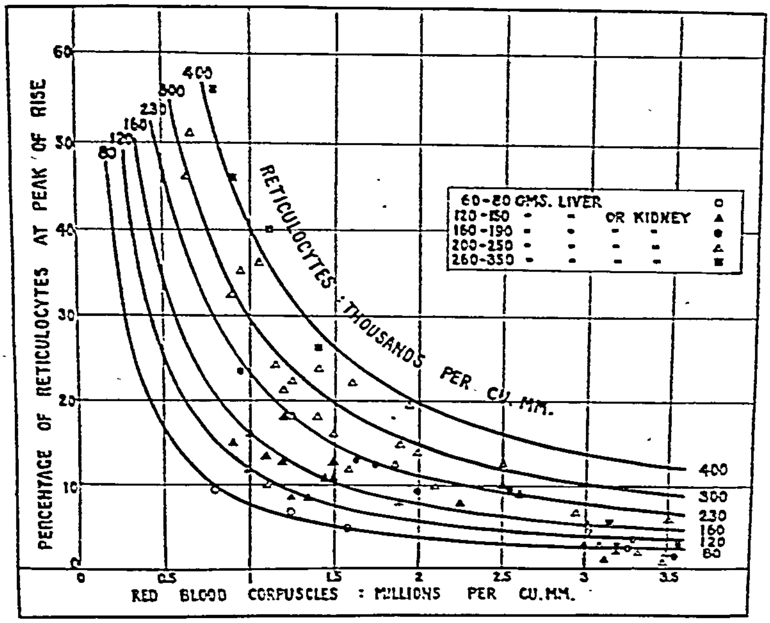

FIG. 2.—Height of the reticulocyte peaks in the responses of individual cases of pernicious anæmia to the daily administration of the amounts of liver or of kidney indicated plotted against the red blood-cell level existing at the beginning of treatment. Note that there is an inverse relationship between the red blood-cell level and the height of the reticulocyte response, and a direct relationship between the latter and the amount of material administered. (From Minot, Murphy, and Stetson.[7])

peripheral blood begins to increase and progresses regularly to a maximum value within a period of from three to ten days thereafter. Then the reticulocyte percentage declines steadily over a period of time, usually somewhat longer than that taken for the increase, until it returns to a level close to its original value. When the reticulocyte counts are averaged from observations on several patients given similar amounts of active material, an approximately triangular course or varying height and width is usually observed. The peak reticulocyte value may be approximately the same when determined by single counts on two successive days. More frequent counts near the maximum of the curve often show slightly higher intermediate values which restore the acute apex of the triangle. During the reticulocyte response the age of the reticulocytes, as judged by the amount and character of the granular filamentous substance, shows a progressive transition identifiable as a metamorphosis from young to older forms. Characteristically the increase in the total red blood-cell count may be accounted for up to the peak of the reaction by the increment of reticulocytes. Thereafter, with continued therapy, the red blood-cells increase largely as a result of the delivery of mature erythrocytes. With reticulocyte responses due to small amounts of effective material, the total red blood-cell count may be little increased or may even fall slightly, owing perhaps to an increase of blood volume or to the natural progress of the disease. Indeed, the amount of active principle necessary to cause a maximal reticulocyte response may be less than that required to produce a maximal rate of rise of the red blood-cells. This difference is due to the fact that daily oral doses of material derived from 300 to 400 g. of liver may in individual instances produce apparently maximal reticulocyte responses but a less than maximal rate of rise of the red blood-cells. Analysis of the results obtained in many patients, however (see Fig. 4), demonstrates that, on the average, to produce maximal reticulocyte responses a larger dose is necessary (material derived from 600 g. of liver).

In *uncomplicated* cases given what have been considered maximum amounts of potent material, the red cells rise *on the average* at very nearly the same rate, no matter whether the substance is given intravenously, intramuscularly, or by mouth. In four weeks the red blood-cells increase, on the average, from the vicinity of 1·4 million per cubic millimetre, by about 2·5 million or slightly more. To be sure, in a series of cases selected at random the average increase of red cells for those given material parenterally will be slightly greater because some of the cases treated orally may have difficulty in absorbing or utilising the material from the gastro-intestinal tract, and because the parenteral dosage commonly used tends to be supramaximal.

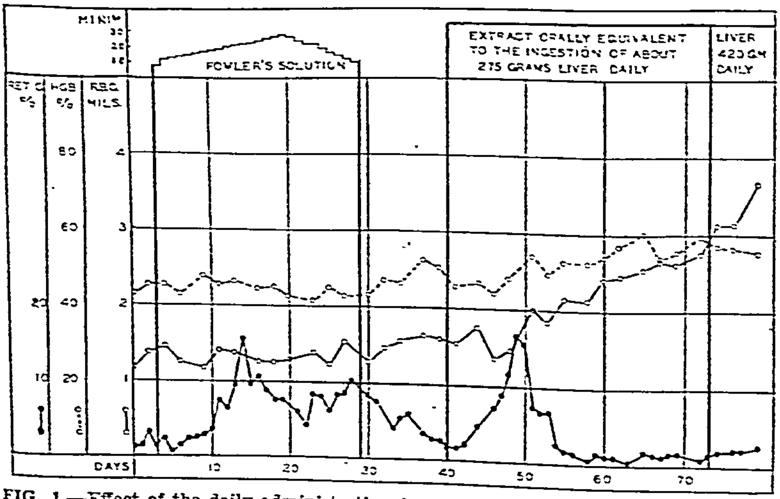

FIG. 1.—Effect of the daily administration in pernicious anæmia of Fowler's solution (potassium arsenite) followed in a subsequent period by liver extract. The reticulocyte response to Fowler's solution, although irregularly maintained for over twenty days, is not associated with a significant increase of the red blood-cells or of the hæmoglobin. The subsequent orderly reticulocyte response to liver extract is typical in time of onset and duration, and is followed by a rapid rise of the red blood-cell count characteristically exceeding the rate of hæmoglobin production, so that the colour-index becomes normal, then less than normal.

In pernicious anæmia, as the red blood-cells rise in response to the administration of active principle, their increase in number frequently outstrips the rate of hæmoglobin regeneration and the changes in physical character of the red blood-cells. An increased mean corpuscular volume becomes normal or less, and the mean corpuscular hæmoglobin concentration and colour-index tend to fall, sometimes below normal values. Somewhat the reverse of this process occurs in the response of hypochromic anæmia to iron. Here, the hæmoglobin regeneration proceeds more rapidly than the increase of the red blood-cells, especially as the latter are frequently not greatly diminished as compared with the hæmoglobin. As the colour-index increases, the decreased mean corpuscular hæmoglobin concentration rises and the low mean corpuscular volume, which may increase very rapidly during the reticulocyte response, eventually becomes normal.

In pernicious anæmia there is evidence that the blood-platelets may be increased somewhat earlier than the reticulocytes, and that in general the diminished white blood-cell count is increased towards normal or slightly above in a variable relation *to the reticulocyte response. It is worth noting* that the patient may sometimes be subjectively improved or show slightly more colour in the hands or face before any changes in the reticulocytes have appeared and frequently before the total red blood-cell count has risen. Likewise the plasma bilirubin may decline sharply as the reticulocytes increase.

The details of the onset, duration, course, and amount of the reticulocyte reaction in pernicious anæmia depend particularly upon (1) the initial red blood-cell level; (2) the amount of active material given; (3) the portal of entry to the body; (4) the rate at which the material enters the body; and (5) the reactive state of the bone-marrow. In the ensuing discussion each factor will be considered in turn, with the assumption that the other four are average and uniform. In the actual interpretation of a given response all the factors must be evaluated.

EFFECT OF THE INITIAL RED BLOOD-CELL LEVEL

If a large uniform daily dose of active material is given to each of several patients with pernicious anæmia, an inverse relationship between the peak value of the reticulocytes and the initial red blood-cell count is observed.[7] This fact is shown by the data plotted in Figs. 2 and 3. *The relationship between the initial red blood-cell level and the maximal percentage value of the reticulocyte response* holds irrespective of the source of the material or the method of its administration. It is, of course, not proper *to compare the absolute values of the reticulocyte peak* produced with one type of material or method of administration with those produced by another, but the same material given in identical dosage demonstrates the inverse ratio. In patients with over 3 million red blood-cells per cubic millimetre, the reticulocyte responses become variable and may not appear despite a significant effect upon the total red blood-cell count. It is probable that under these circumstances the demand of the anæmia upon the bone-marrow is not sufficient to cause delivery of immature cells into the blood stream, or that the proliferation of the primitive red blood-cells in the bone-marrow is not sufficient to provide a large amount of tissue for rapid maturation.

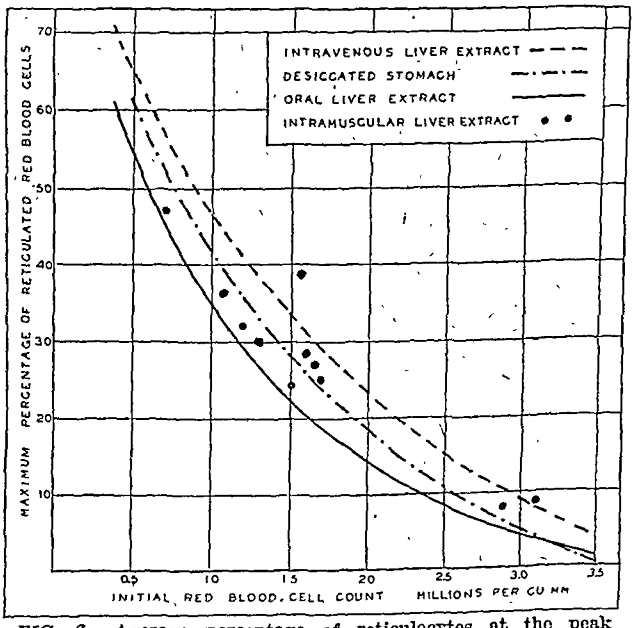

FIG. 3.—Average percentage of reticulocytes at the peak of their rise in response to different types of maximally effective therapy in pernicious anæmia plotted against the initial red blood-cell count. From above downwards the curves indicate average responses from single intravenous injections of extract derived from 100 g. of liver, from the daily oral administration of material derived from 265 g. of *pig's stomach, and from the daily oral* administration of extract derived from 600 g. of liver, respectively. The solid dots indicate the individual responses of 11 patients given daily by intramuscular injection extract derived from 10 g. of liver. (Based on figure by Bethell and Goldhamer.[13] Some of the *data for* intramuscularly administered liver extract were kindly supplied by Dr. Raphael Isaacs.)

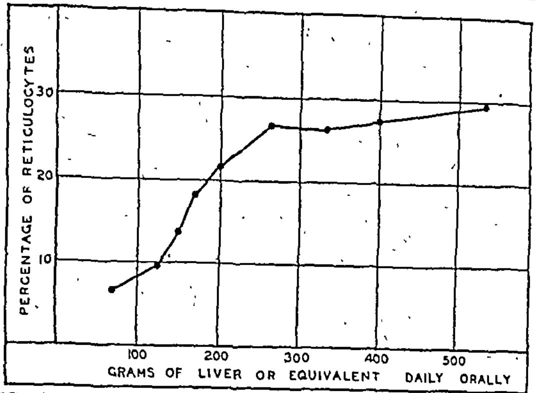

FIG. 4.—Relationship between the dosage and the height of the reticulocyte response to the daily oral administration of liver or of liver extract in a hypothetical case of pernicious anæmia with an initial red blood-cell level of 1·25 million per c.mm. The data are derived from observations with liver pulp or with a liver extract conserving about two-thirds of its potency in 99 patients with *initial* red blood-cell levels of between 1 and 2 million per c.mm. The expected responses in the hypothetical patient with an *original red blood-cell* level of 1·25 million per c.mm. were calculated when necessary by interpolation, using the slope of the curve shown in Fig. 2 most closely approximating the data of each observation. *The averages so obtained from the daily administration* of the amounts of liver or equivalent extract indicated are shown by the individual points on the line.

EFFECT OF THE AMOUNT OF POTENT MATERIAL

If to each of several patients with pernicious anæmia and the same initial red blood-cell level various amounts of effective material are administered in uniform daily dosage, it appears that there is a direct relationship between the amount of material given and the peak of the reticulocyte value. This effect, however, approaches a maximum at a decreasing rate as the amount of active material is increased, as shown in Fig. 4. Thereafter an increase of the amount of active material produces no greater increase of the peak value of the reticulocytes but may accelerate the rate of increase of the red blood-cell concentration. In Figs. 2 and 3 are shown the effects of the administration of various amounts of liver [7] and other potent substances for oral or parenteral use [12, 13] upon the production of reticulocytes. Table I. shows the approximate amounts of various sources of active material for oral or parenteral use which may be expected to yield just maximal reticulocyte responses upon uniform daily administration in uncomplicated cases.

EFFECT OF THE ROUTE OF ADMINISTRATION OF POTENT MATERIAL

The effectiveness of liver extract when rectally administered is very slight compared with its activity upon oral administration, according to a few observations. If the same amount of a given active material is administered in uniform daily doses by mouth and by intramuscular injection in patients with comparable degrees of anæmia, striking differences in the effectiveness of the material are observed. The most accurate comparisons have been made between the effectiveness of the daily oral administration of the liver fraction "G" of Cohn and of the daily intramuscular injection of a dilute aqueous solution of the same material. Although the data are scanty, it is evident that the effect of the daily oral administration of this extract derived from 600 g. of liver is usually no greater than the effect of the daily parenteral administration of the same material derived from 10 g. of liver.[13] Data from certain observations leading to this conclusion are plotted in Fig. 3. It is, therefore, probable that material administered by the parenteral route is at least sixty times as effective as when given by mouth to the average patient. In certain patients, owing possibly to difficulty in the absorption of orally administered material, this ratio is apparently increased. The existence of an intestinal barrier is probably to some extent a physiological phenomenon in regard to the absorption of material in liver extract, iron, and other substances. Whether in certain patients with pernicious anæmia increased difficulty in absorption entirely accounts for the relatively slight effects of the usual oral doses of liver extract has not been finally established (see Fig. 5). There is evidence that the effectiveness of equal amounts of liver extract given intramuscularly in different patients is also variable. Since it is not known with certainty that effective parenteral preparations of gastric tissue can be made, there is no evidence concerning the relative effectiveness of this material when administered by injection.

EFFECT OF THE RATE OF ADMINISTRATION OF POTENT MATERIAL

The rate at which the active principle reaches the bone-marrow evidently produces certain modifications in the reticulocyte response. In general the effect of a single massive dose of orally[15] or parenterally[16] administered material is to accelerate the appearance of increased numbers of reticulocytes in the blood stream and to increase the peak value. The tendency for large uniform daily doses of material to cause earlier reticulocyte responses than smaller doses also acts in a similar way.

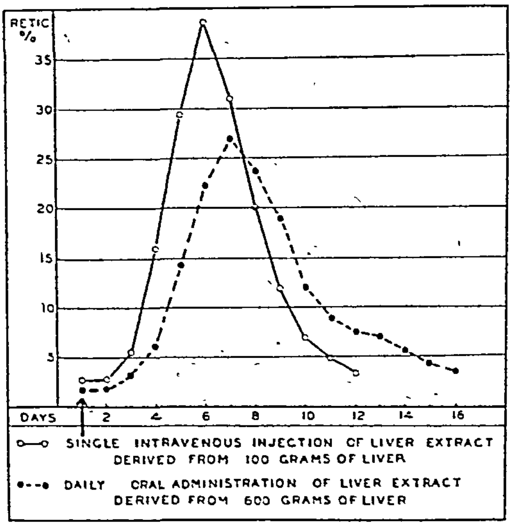

FIG. 6.—Average daily percentage of reticulocytes in patients with pernicious anæmia responding to maximally effective amounts of liver extract administered by a single injection (13 cases) and in uniform daily doses by mouth (20 cases). The average red blood-cell level before treatment for each of the two groups was about 1·2 million per cubic millimetre. (From Minot.[11])

On the contrary, the daily administration of small doses of active principle tends to produce a prolonged low curve with a delayed and not very acute apex. In the case of parenterally administered liver extract, perhaps especially when given intravenously in a single large dose, there may be an additional non-specific or irritant effect possibly augmenting the production of reticulocytes by the bone-marrow, since of course the commercial extracts so far available are far from being pure sources of the active principle.

In Fig. 6 are shown the average daily percentages of reticulocytes resulting from maximally effective amounts of liver extract given intravenously in a single dose and in uniform daily doses by mouth respectively to each of two groups of patients with pernicious anæmia with initial red blood-cell levels in the vicinity of 1·2 million per cubic millimetre. There is a difference of about 42 per cent. in favour of the intravenous injections when the percentages of reticulocytes at the peaks of their rises are compared. If the sums of the daily percentages of reticulocytes above the level of 5 per cent. are calculated, there is still a difference of 17 per cent. in favour of the intravenous injections. By multiplying the daily percentage values for the reticulocytes by the total number of red blood-cells, however, the absolute number of reticulocytes present at each observation can be calculated.[17] When this is done, sums of the daily numbers of reticulocytes poured forth above the basal level of 60,000 per cubic millimetre of blood are found to be, within 1 per cent., the same for each method of administration.[18] Whatever the physiological implications of these facts, it is apparent that in evaluating reticulocyte responses from percentage data for peak values, identical methods of administration must be used. Otherwise certain calculations must be performed with absolute values.

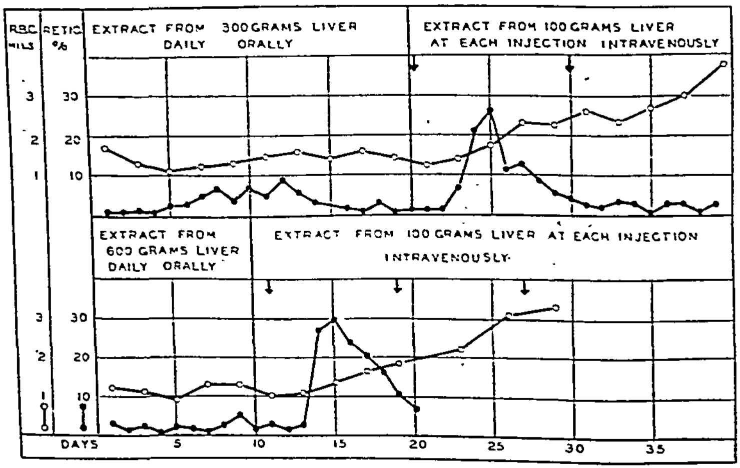

FIG. 5.—Comparison of the effectiveness of a liver extract upon oral and parenteral administration in two cases of macrocytic anæmia. In the upper part of the figure is shown the relatively slight reticulocyte response and effect upon the red blood-cell level produced by the daily oral administration of a liver extract derived from 300 g. of liver, followed by a striking response to a single intravenous injection of the same material derived from 100 g. of liver.

The lower part of the figure shows the negative response in a second patient to the daily oral administration of an extract derived from 600 g. of liver, followed by a striking reticulocyte and red blood-cell response after a single intravenous injection of the same material derived from 100 g. of liver. Note, however, that the peak of the reticulocyte response (30 per cent.) to the latter is not so great as would be expected (47 per cent.) according to the values shown in Fig. 3. This fact suggests that the failure of the patient to react to the orally administered material is not due entirely to difficulty with absorption, but depends to some extent upon ineffectual internal utilisation. (Upper figure from Castle and Taylor: Jour. Amer. Med. Assoc., 1931, xcvi., 1198; lower figure from Castle, Heath, and Strauss: Amer. Jour. Med. Sci., 1931, clxxxii., 741.)

EFFECT OF THE REACTIVE STATE OF THE BONE-MARROW

The discussion so far has been based on the results obtained in the average patient with pernicious anæmia. In addition to a consideration of the foregoing factors, it is necessary to recognise the fact that certain patients are more or less able than the average subject to develop a reticulocyte response. Thus patients whose initial level of reticulocytes is in the vicinity of 5 to 8 instead of the usual 1 to 3 per cent. may be expected to respond more readily but to give less marked increases at the peak. In general older persons and those with arterio-sclerosis respond less readily than younger ones. Extensive neurological involvement is often associated with slightly lower reticulocyte responses. Severe damage to vital organs, such as the liver, is prone to inhibit reticulocyte responses. By analogy with other anæmias it is clear that toxic factors, such as may be associated with nitrogen retention, may act in a similar way. Infection of a variety of types may greatly inhibit the reticulocyte response. In Fig. 7 is shown the temporary depressing effect of an intercurrent infection upon the bone-marrow response of a patient with pernicious anæmia already responding to liver extract. Difficulty with the absorption of material from the alimentary tract, although not strictly concerned with the reactive stage of the bone-marrow, may, as discussed above, be responsible for lessened reticulocyte responses or even for their absence in certain patients (see Fig. 5).

Theoretically, if acute blood loss has occurred shortly before the administration of specific therapy, the pre-treatment blood level will be lower than that naturally corresponding to the state of the bone-marrow; and the effect of the therapy in producing reticulocytes will really correspond to the blood level existing before the bleeding occurred. If a large transfusion of blood has preceded the administration of active principle, the situation will be reversed in an uncomplicated case. If, however, in such a case some degree of iron deficiency existed, the transfusion might allow an especially large reticulocyte response from the administration of liver extract because hæmoglobin would be supplied to the cells in the bone-marrow at the same time as the active principle of liver extract. In many patients there are probably other defects of nutrition besides the deficiency of "liver extract," especially iron deficiency. The reticulocyte response to liver extract, in such cases of atypical pernicious anæmia as have a less increased cell size than usual or some degree of hæmoglobin reduction, may be retarded by the existence of the additional deficiency. Such an effect is apparently common in the anæmia of sprue.

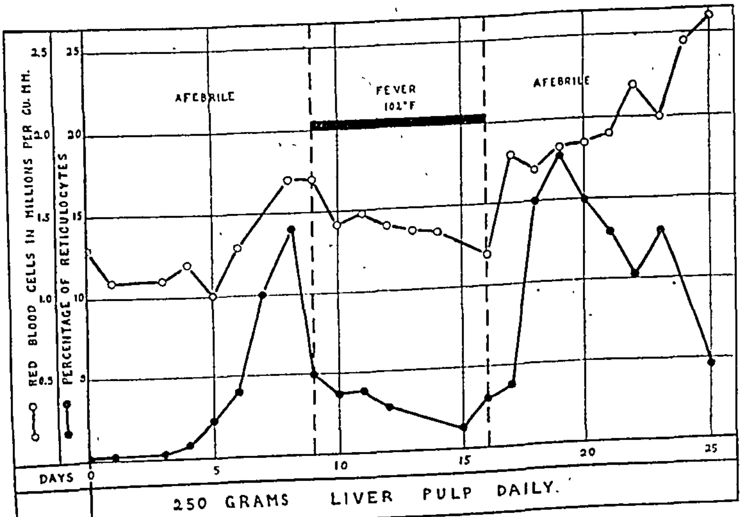

FIG. 7.—Temporary depressing effect of intercurrent infection with fever upon reticulocyte and red blood-cell production during response to the daily administration of liver in pernicious anæmia. (From data kindly supplied by Dr. O. H. Robertson.)

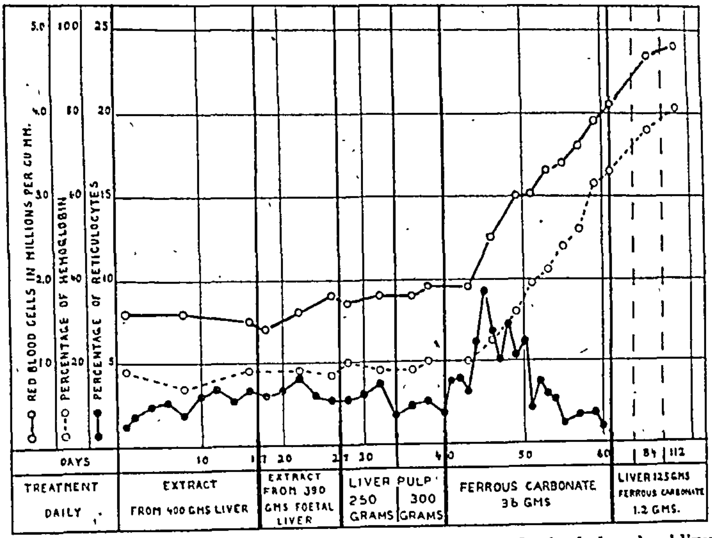

FIG. 8.—Negative effect of calves' liver preparations and of whole calves' liver in "idiopathic" hypochromic anæmia, followed by a positive effect of iron upon reticulocyte production and red blood-cell and hæmoglobin values. (From Mettier and Minot: Amer. Jour. Med. Sci., 1931, clxxxi., 25.)

Use of the Reticulocyte Reaction as a Test of the Physiological Responses of the Bone-marrow

With due attention to the variables involved, the reticulocyte response may obviously be used to ascertain the reactive state of the red cell forming tissue. The presence of increased numbers of reticulocytes, taken with leucocytosis and increases of blood-platelets, is in general a feature of anæmias associated with increased bone-marrow activity. Such a condition exists more or less constantly in chronic hæmolytic anæmias in which toxic depression of the bone-marrow is not present. Exceptions, due to "irritation" of the marrow in the anæmia of leukæmia or of metastatic disease of the bone-marrow, have been mentioned above.

After an acute hæmorrhage, the height to which the reticulocytes will rise depends on the amount of blood lost and the ability of the marrow to react. Accurate data from animal experiments have recently been published,[19] showing that there is a striking quantitative relationship between the reticulocyte response and the amount of blood lost. Equally good data are not available in man, but unpublished data in our hands indicate that in general the principle has been well established qualitatively. If, after a considerable hæmorrhage, the reticulocytes do not show a wave-like increase, the presence of some deficiency, often of iron, due to previous hæmorrhage or to long-standing defective diet or nutrition, may be hypothecated. Based on these principles, numerous examples of the value of daily observations of the reticulocyte percentage at critical times might be cited. A diagnosis of unsuspected intestinal hæmorrhage may be made as a result of finding the reticulocytes considerably elevated in a patient who has suddenly become weak for no obvious reason. Occasionally chronic carbon monoxide poisoning may be correctly diagnosed because of increased reticulocytes in the presence of a normal red blood-cell and hæmoglobin level.

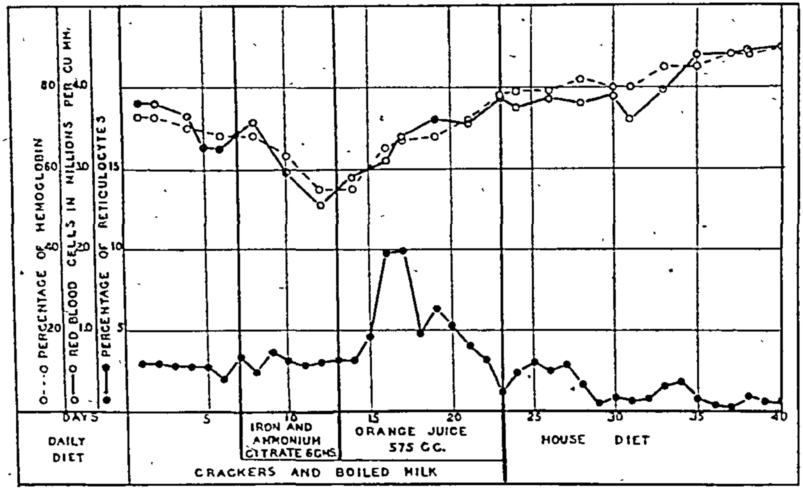

FIG. 9.—Negative effect of the daily administration of iron in a patient with anæmia and scurvy. Note the subsequent reticulocyte response to orange juice and the increase of blood values. The patient was kept on a vitamin-C deficient diet during these observations. (From Mettier, Minot, and Townsend.[11])

In the analysis of the physiological basis of various types of nutritional deficiency anæmias, daily observations of the course taken by the reticulocytes probably constitute the best single criterion. During successive ten-day to fifteen-day periods certain sources of active material are administered in uniform daily doses known to be maximally effective in typical instances of various types of deficiency anæmia.

Thus, in definitely anæmic patients the failure of a reticulocyte response to appear after the parenteral injection of liver extract, or after the oral administration of iron or of orange juice, may be taken to indicate that there is not a deficiency of these substances. Thus the diagnosis, for example, of pernicious anæmia, iron deficiency anæmia, or the anæmia of scurvy, respectively, would be excluded. On the other hand, reticulocyte responses in one or more such successive periods of observation may indicate the respective degree of participation of such factors in the cause of the anæmia. In Fig. 8 is shown the negative effect of liver preparations and of whole liver, respectively, in successive periods of administration in hypochromic anæmia. Finally, the reticulocytes increased with iron therapy and there was a rapid rise of red blood-cells and hæmoglobin. In Fig. 9 is shown the reticulocyte response of a patient with a blood picture resembling very much that of pernicious anæmia. As is seen, the patient while kept on a vitamin-C deficient diet did not respond to iron therapy but showed a typical reticulocyte rise consequent upon the administration of orange juice. The ineffectiveness of purified liver extracts has been shown in other patients with the anæmia of scurvy under similarly controlled conditions. Fig. 10 illustrates the participation of both a deficiency of "liver extract" and a deficiency of iron in the production of anæmia responding with successive reticulocyte reactions to the administration of each of these substances. The blood picture was moderately hypochromic and the response to liver extract unexpectedly revealed the complexity of the deficiency.

The presence of "resistance" to the oral administration of liver extract may be demonstrated by the method of successive test periods. In the lower portion of Fig. 5 is shown the absence of a reticulocyte response in a patient given liver extract derived from 600 g. of liver daily, and the presence of an excellent reticulocyte response to a single intravenous injection of liver extract derived from 100 g. of liver in a subsequent period. Ideally, the observation should have been carried out by the subsequent uniform daily parenteral injection of extract derived from 10 g. of liver in order that the amounts and rates of administration of active principle in each period would be comparable.

Finally, the removal of toxic inhibition of the bone-marrow due to the presence of infection may be demonstrated by following the daily course of the reticulocytes after the elimination of the infection. In Fig. 11 is shown the effect of removing the parasites in a patient with malaria. The temporary increase of reticulocytes, following treatment with quinine, indicates the effect on the bone-marrow of abolishing the inhibition due to fever or in some manner to the presence of the malarial parasites. Had the hæmolytic process only been abolished, the reticulocytes would merely have declined without the distinct elevation after the successful treatment for malaria.

Use of the Reticulocyte Reaction as a Test of the Potency of Therapeutic Agents

SINGLE RETICULOCYTE RESPONSES

Although there are now promising methods for the testing of the material active in pernicious anæmia by the use of animals, the patient is the basis of the present methods for establishing the effectiveness of experimental or commercial products. Despite

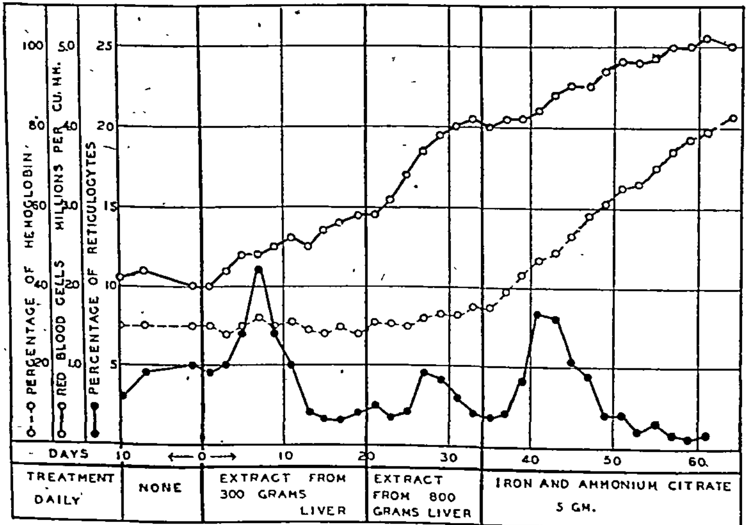

FIG. 10.—Effect of liver extract and of iron in successive period of daily administration in a patient with normocytic anæmia with a moderately low colour-index. Note the three reticulocyte responses: the first from a liver extract ordinarily ineffective in hypochromic anæmia but effective in pernicious anæmia; the second from an increase in dosage; and the third in response to iron therapy. The dominant effect of the liver extract in increasing the red blood-cell count and of the iron in increasing the hæmoglobin level is clearly shown.

much that has been written, it is evidently not clear to many physicians how such tests should be conducted. Therefore the technique of using the single and the "double" reticulocyte reaction method for the determination of the potency of therapeutic substances will be described.

The use of the reticulocyte reaction as a test of comparative potency is applicable only to substances already known from their general clinical and hæmatological effects to be specific.

With substances whose regular clinical effectiveness is not clearly established (e.g., Fowler's solution), a reticulocyte response does not necessarily mean a replacement of a specific deficiency. Especially with parenterally administered substances the possibility of non-specific effects (e.g., concentrated gastric juice) is to be considered. Even with parenterally administered liver extracts, especially in large intravenous dosage, a partial non-specific effect upon reticulocytes may occur. For this reason it is preferable to administer therapeutic substances in uniform daily dosage, and if parenterally, by intramuscular injection. Under any circumstances if a large reticulocyte response appears without a significant increase of the red blood-cells a non-specific effect is to be suspected. Thus if a new product is to be considered effective, not only must it produce an appropriate reticulocyte response, but an appropriate increase of red blood-cells must follow. However, distinctly submaximal dosage of material *known to be clinically effective* will produce a small reticulocyte response for the given blood level, and a significant increase of the red blood-cells may not follow because the quantity given was small.

The reticulocyte response has certain advantages over the method of observing the rate of rise of the total red blood-cell count.

In the first place, it is a more delicate test because reticulocyte responses can be detected following doses of material quite insufficient to produce a distinct increase of red blood-cells. In the second place, if the red blood-cell count is used, it is necessary to allow a much longer period of time to elapse than if the reticulocyte reaction is studied. With the former a period of at least a month is desirable; with the reticulocyte response, ten to fourteen days is almost always sufficient. In either case controlled dietary conditions must be maintained, since the patient's ability to utilise certain foods for the formation of effective material through his own gastric mechanism may be present or especially may return during the induced remission.

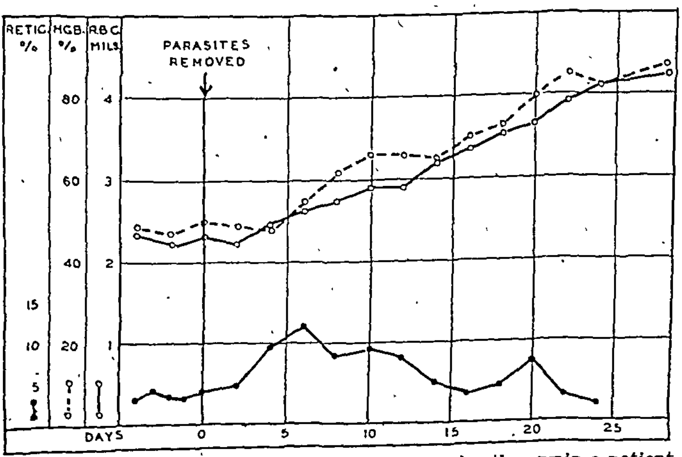

FIG. 11.—Effect of removal of parasites with quinine therapy in a patient with hæmolytic anæmia due to malaria. Note the temporary rise of reticulocytes indicating removal of the inhibition of blood production. This increase of reticulocytes would not have occurred had only blood destruction been abolished.

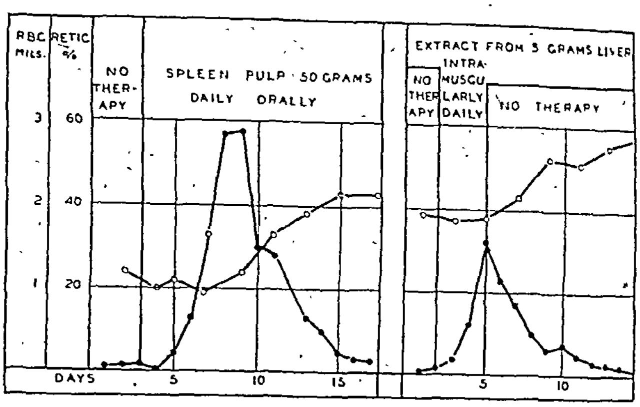

FIG. 12.—Reticulocyte responses in two patients with pernicious anæmia beginning too soon after the initiation of the method of therapy used to be a result of it. The reticulocyte response to spleen pulp began on the second day of administration; and the material was subsequently shown to be ineffective in other patients. The reticulocyte response to the daily intramuscular injection of liver extract began within 24 hours and was actually a typical response to active material subsequently discovered to have been ingested by the patient six days previously.

When the rise of the red blood-cells is used, the prolonged period is necessary because of the variable interval after the initiation of therapy at which the response begins. Therefore, in order to secure a good estimate of the rate of rise, it is necessary to determine the result over a considerable period. Moreover, the rise of the red blood-cells occurs at a constantly diminishing rate which makes comparisons with different initial red blood-cell values somewhat difficult. Thus, for example, what may be considered an excellent rise in a month from a level of 3 million would be considered an unsatisfactory rise from a level of 2·8 million per cubic millimetre. Finally, the data concerned with the rate of rise of the red blood-cells under controlled conditions have not been so carefully worked out as those concerned with the reticulocyte response.

An objection which applies both to the use of the rise of the red blood-cells and to the use of a single reticulocyte response for evaluating the potency of material is the fact that the results obtained from observations on several patients must be treated statistically in order to eliminate individual variations. By the use of the method of the double reticulocyte response, it is possible to compare in the same patient the effect of one or more substances and so largely avoid the effect of variations in individual susceptibility. In view of the present scarcity of suitable patients and the well-recognised variability of different individuals in their responses, especially to orally administered material, this method has overwhelming advantages.

Before proceeding to a discussion of the double reticulocyte phenomenon, it should be mentioned that data are available for the use of the single reticulocyte peak under certain defined and *adequately controlled* conditions. The factors involved in the reticulocyte reaction have been discussed in detail above, and average values for the expected results, in respect to reticulocyte response (see Figs. 2 and 3), have been given.

The most common error in the use of such data has been the failure to determine what amount of the substance to be tested is just sufficient to produce maximal or slightly submaximal effects upon reticulocytes. In the Table are shown the average amounts of various therapeutic agents yielding just maximal reticulocyte responses. Obviously, considerable losses of potency may occur and remain undetected if supramaximal dosage is employed. Thus, for

Table showing Approximate Daily Amounts of Substances Necessary to Produce Maximal Reticulocyte Responses in Pernicious Anæmia

Substance.	Original weight in grammes.	Prepared weight or volume.	Route of administration.
Liver or kidney [7]	500	400 g.	Oral.
Desiccated hog stomach [12]..	250	30 g.	,,
Liver extracts— Aqueous concentrate [14] ..	500	65 c.cm.	,,
Precipitate 95% alcohol: fraction "G" [8]	600	27 g.	,,
Dilute solution of fraction "G" [13]	10	2 c.cm.	Im.
Concentrated solution of fraction "G" (commercial)	20	0·6 c.cm.	,,
Liver-stomach preparation [22]	20	4·5 g.	Oral.

Im. = Intramuscular.

example, in testing the effectiveness of a given product for oral use expected to be just maximally effective in daily amounts derived from 400 g. of liver, the daily dose employed in testing should be that derived from not more than 400 g. of liver. Secondly, particularly in regard to the reticulocyte reaction, the necessity for uniform methods of administration has been neglected, perhaps because the importance of this feature of the test has not been sufficiently realised.

The best data available are based either on the uniform daily administration of potent substances or on equal injections of liver extract at intervals of either a week or ten days. It is clear that, in order to compare results upon reticulocytes, the methods of administration must be uniform.

As indicated above, the effect of a single large dose of material or of a single intravenous injection is to produce a somewhat greater percentage of reticulocytes at the peak of their rise than the same dose of material evenly distributed over several days. Sums of the daily numbers of reticulocytes produced during the period of elevation by each method of administration are about the same. Errors in determining the number of red blood-cells or the percentage of reticulocytes will multiply the final error. Obviously, under these conditions irregular and variable dosage renders it impossible to make satisfactory comparisons. It is thus easier to arrange beforehand for a uniform method of administration best suited to the standard data available and to compare simply the peak percentage value of the reticulocytes. Usually this is best effected by giving a uniform daily dose until the reticulocyte peak has been passed. By continuing the administration, the rise of the red blood-cells at the end of thirty days can be used as a check.

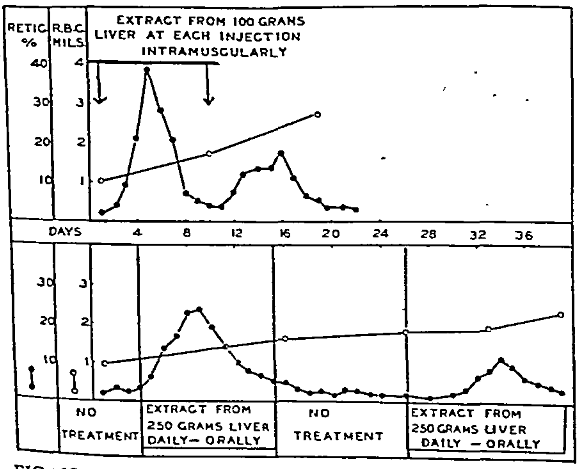

FIG. 13.—Effect upon reticulocyte production in pernicious anæmia which may occur with discontinuous therapy even when equal amounts of active substance are used. Under these circumstances the appearance of the second reticulocyte response obviously does not indicate the greater potency of the second substance administered.

If a given uniform daily dosage of a certain preparation is just sufficient in the average patient to produce a maximal reticulocyte response, it cannot be assumed that reduction of the dosage will have a proportionately diminished effect in producing reticulocytes. Since there is a diminishing rate of approach to the maximal effect upon reticulocyte production as the dosage is increased (see Fig. 4), the peak value produced by one-half the maximal dose will not be one-half, but more nearly three-quarters that expected from the maximal dose. It is therefore impossible to draw quantitative conclusions as to the relative potency of different sources of active principle by comparing in a "mathematical" fashion the percentages of reticulocytes produced. Comparisons are best made on the basis of the determination of the amounts just sufficient to produce maximal effects.

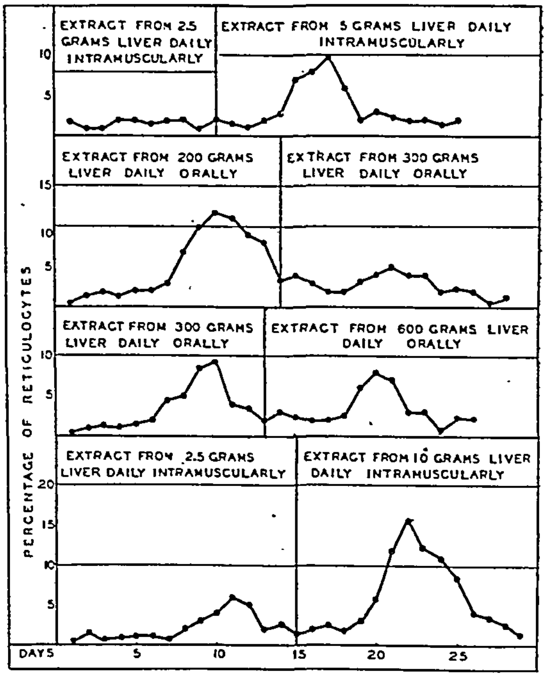

FIG. 14.—Observations of "double" reticulocyte responses in each of four patients with pernicious anæmia. In the first patient there was actually no reticulocyte response in the first period. In the other three patients reticulocyte responses, respectively less than, approximately equal to, and greater than the first reticulocyte response appeared in the second periods. The significance of each complete observation is the same: the substance given during the second period was of greater potency than the substance given during the first period.

It is the glory of the medical profession that it is untiring in the service of suffering mankind, but the doctor's humane impulse to "get the patient well" is often oblivious to the austere necessities of scientific observation during the attainment of that desirable objective. The conduct of a controlled observation upon reticulocyte production demands that the improvement be measurable, not haphazard. The patient will benefit from treatment no less because its effects are critically examined, and his future security and that of other patients suffering from the same disease may depend upon information concerning the potency of the remedy so obtained.

Remarkable as it may seem, attention to such *obvious details* as the elimination of other sources of active material than the substance under test, or of the complications introduced by blood transfusion or previous therapy, has not always been observed. Thus, it is essential that the patient has not recently received active material or is not receiving it in the diet during the test, in the form of liver or kidneys. If a certain amount of gastric intrinsic factor remains, potential sources of liver extract exist in the form of dietary (extrinsic) factors, such as meat, eggs, whole grains, yeast, and probably other substances. For this reason the diet of the patient should not contain such substances during observations. A control period of a few days is desirable in order to establish the constancy of the reticulocyte level and thus the uniformity of the reactive state of the bone-marrow before the administration of active material.

The following examples serve to emphasise the importance of paying scrupulous attention to the character of the reticulocyte response, especially in respect to its time relations to the test substance.

In Fig. 12 are shown two striking reticulocyte rises immediately following *but not due to administration of the substances indicated.* The response in the first patient to orally administered spleen pulp began within two days; that in the second patient to the intramuscular injection of a liver extract began within twenty-four hours. Such rapidly developing effects upon reticulocyte production are never seen under these conditions of administration; both responses were therefore considered to be unrelated to the therapy indicated in Fig. 12. Subsequent observations with spleen pulp demonstrated its complete negativity; and this reticulocyte response has not been explained except as "spontaneous." The second patient was subsequently found to have taken a considerable amount of an effective commercial preparation before coming under observation, on the sixth day preceding the beginning of the reticulocyte response.

Unfortunately, examples of similar atypical reticulocyte responses have appeared in the literature as evidence of the potency of commercial products.

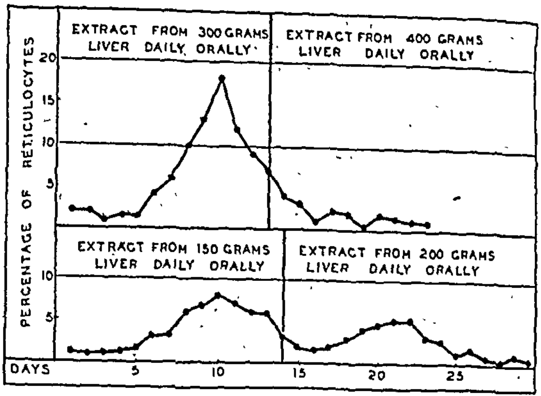

FIG. 15.—In the upper part of the figure the relatively large dosage of liver extract (one-half maximal) given a patient with pernicious anæmia has yielded only a slightly submaximal reticulocyte response, and thus prevents a second reticulocyte response when this dosage is increased by one-third. In the lower part of the figure the reticulocyte responses of a second patient to a proportionate reduction of each dosage are shown. During the first period an increase of reticulocytes appeared in response to about one-quarter of the maximally effective dose of liver extract and was then followed by a second reticulocyte rise when this dosage was increased by one-third, as in the first patient.

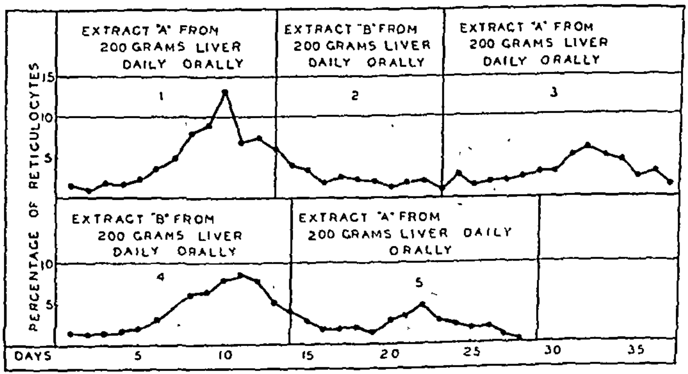

FIG. 16.—Effect of reversing the order of administration of two liver extracts for oral use in pernicious anæmia, an extract A of unknown potency and a standard extract B. Extract A represents a lot of material manufactured according to a process designed to produce material of the potency of standard extract B. It is known that a maximal reticulocyte response can be obtained from the daily oral administration of standard extract B derived from 600 g. of liver. One-third of this dosage is chosen in order to yield a definitely submaximal effect upon reticulocytes. At the end of periods 1 and 2 no conclusion is possible; at the end of period 3, extract A has been found to produce a reticulocyte peak subsequent to the administration of standard extract B derived from an equal amount of whole liver. It is therefore shown to be of greater potency than standard extract B. In a second patient reversal of the order of administration employed in periods 1 and 2 of the first patient is made in periods 4 and 5; and, as in periods 2 and 3, extract A is shown to be of greater potency *in terms of original liver than standard extract B.*

"DOUBLE" RETICULOCYTE RESPONSES

The method of the double reticulocyte response demands careful attention to detail, but since the variations of different individuals are eliminated and the standards derived from other observations are not critically involved, its interpretation is relatively simple. The principle of the method depends on the fact that the uniform daily administration of a source of active material, large or small, will never produce more than one reticulocyte response unless the *reactive state of the patient intermittently changes.* If during a period of from ten to fourteen days active material in distinctly submaximal quantity is given in uniform daily dosage, a less than maximal reticulocyte response will appear and decline. Now, if during a second period of days a distinctly greater quantity of the same material is given in uniform daily dosage, a second reticulocyte response will usually result. The technique of conducting such observations and their interpretation will now be considered in detail in reference particularly to pernicious anæmia. The examples cited, however, serve to illustrate certain points common to the use of the reticulocyte reaction not only in responses to liver and allied products but in responses to hæmatopoietic substances in any type of deficiency anæmia.

Necessity for the Uniform Daily Administration of Potent Material.—If an effective amount of potent material is administered *in a single* oral dose or injection, a *reticulocyte* response will appear. If, however, later than five days thereafter an identical amount of the same material is administered in the same way, a second, usually smaller, reticulocyte response may occur (see Fig. 13). Since the *second* dose of the material was exactly as potent as the first, this indicates *that* in the interval the effect of the first substance was "wearing off," and that the bone-marrow was at least partially ready to respond again. For the same reason if an interval is allowed to elapse between two periods of the uniform daily administration of equal units of active material, a *second* reticulocyte peak may be produced (see Fig. 13). A corollary to this situation would be the administration of daily but variable doses of material, since with such a procedure, as with discontinuous therapy, the effect on the bone-marrow would be to some extent variable also. It is evident, therefore, that the "stimulus" to the bone-marrow should in theory be continuously and evenly applied. In practice this can best be done by giving either by mouth or by injection a uniform daily dose of the active principle to be tested. Naturally the route of administration—oral or parenteral—must be the same in both periods of observation.

Necessity for Submaximal Dosage of Potent Material.—If a maximally effective amount of active principle is given continuously during the first period, it is obvious that the bone-marrow will not be able to respond further to an immediately subsequent daily administration of more potent material. Under the conditions defined, a twofold or even a threefold increase of the amount of active principle has no additional effect. Therefore, in the conduct of the double reticulocyte reaction, *it is necessary to know from other observations what will be a daily submaximal dose of the substance under test.* In order to allow the greatest opportunity for a second reticulocyte response due to the administration of material of potentially greater activity in the second period of observation, it is desirable to use in the first period of observation a dose just sufficient to produce a distinct reticulocyte reaction; from a quarter to a third of the maximal dose is usually satisfactory. With such dosage the possibility of a second increase of reticulocytes is facilitated.

Positive Significance of a Second Reticulocyte Response.—If, following the administration of a substance in the first period, there is during a second period an orderly response of reticulocytes, no matter of what degree, to a second substance, this substance is known to be more potent than the first. It is emphasised that this conclusion is justified whether or not there was a reticulocyte response during the first period and whatever the relative magnitude of the reticulocyte response in the second period. Fig. 14 shows in the second periods of four different cases reticulocyte responses of various heights relative to the responses in the first periods. Each is indicative of the greater potency of the second substance. If the absolute numbers of reticulocytes are calculated, the effect of the rise of the total red blood-cell count will be to increase the relative height of the second reticulocyte peak, but its significance will not be altered. It is, of course, essential that the peak of the first reticulocyte response has definitely been passed before the administration of the second substance is begun. The administration of the second substance should never be begun until there have been at least two days on which reticulocyte percentages lower than the peak value have been obtained; and it is advisable to determine that the reticulocyte percentage on the third day is also lower than that on the two preceding days before commencing the administration of the second substance on the third day. It is not advisable to wait until the previous base line has been reached, since this allows an opportunity for too great an increase of the red blood-cell values. There will always be a latent period during the early days of the administration of the second substance before the beginning of the second reticulocyte response. During this time the reticulocyte increase due to the first substance will be further diminishing.

Negative Significance of the Absence of a Second Reticulocyte Response.—If following the administration of a substance in the first period there is during the administration of the second substance no second reticulocyte response, the only conclusion that can be drawn is that the second substance was not shown to be more potent than the first. It is possible that the second substance was merely not sufficiently more potent than the first to produce a second reticulocyte response. Since in order to produce a second response a certain increment of potency is essential, especially at relatively high blood levels, *it is never proper to assume, under these circumstances, that the second substance was less potent than the first,* although this may well be the case. Since the greater the first reticulocyte response the less is likely to be the second, it may be possible to demonstrate, by proportionately reducing the dosage of each substance when given to a second patient (and so producing a smaller first reticulocyte response), that the second substance was actually slightly more potent than the first. Fig. 15 illustrates this point. Because of this fact, in general, the dosage of the first substance given should be as small as possible and still produce a distinct first reticulocyte rise.

Reversal of the Order of Administration.—If there is no second reticulocyte response, especially when the first reticulocyte response has been small, it is possible to decide whether the second substance is less potent than the first by reversing the order of their administration in another patient. Under these circumstances, the absolute or relative dosage of each should be that employed in the first patient. If, in the second patient, a second reticulocyte response is forthcoming, the failure of the second reticulocyte response to appear under the original order of administration is clearly explained; as now the first substance given the first patient has been shown in the second patient to be the more potent. If no second reticulocyte response appears in the second patient, it is clear that neither substance is detectably more potent than the other. By readministering the first substance in the same dosage in a third period in the original patient, the reversal of order may be effected without the use of a second patient. Examples of the results of reversing the order of administration of two sources of active principle are shown in Figs. 16 and 17.

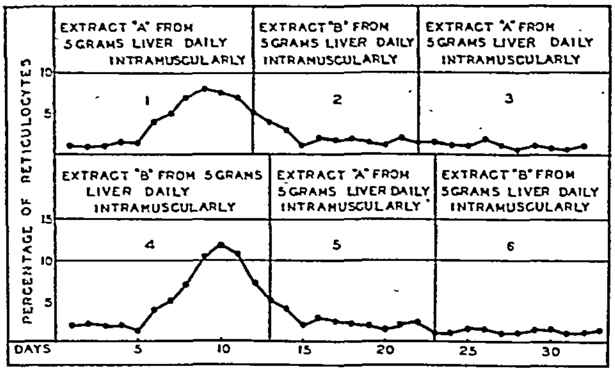

FIG. 17.—Effect of reversing the order of administration of two liver extracts for intramuscular use in pernicious anæmia, an extract A of unknown potency and a standard extract B. Extract A represents a lot of material manufactured according to a process designed to produce material of the potency of standard extract B. It is known that a maximal reticulocyte response will be obtained from the daily intramuscular injection of standard extract B derived from 10 g. of liver. The first patient presenting an opportunity for a test has considerable arterio-sclerosis and therefore a relatively large submaximal dose, that derived from 5 g. of liver, is given daily. At the end of periods 1 and 2 no conclusions can be drawn. At the end of period 3, since no reticulocyte response appeared, no final conclusion can be drawn. Although it may be suspected that extracts A and B are about equal in potency, the patient's blood values may have risen so much as to prevent a reticulocyte response in period 3. In a second patient the order of administration of similar doses is reversed throughout with the same result. The conclusion is now justified, since neither standard extract B nor extract A is able to produce a second reticulocyte rise after the other, that they are equivalent in potency.

The method of the double reticulocyte response can be most readily utilised when a "standard" substance of known potency is available. Its utility in checking lots of material made by the same process is thus manifest. The substance of unknown effectiveness should be given in the first period in uniform daily amounts derived from that quantity of whole organ which is known, in the form of the "standard," to yield a distinctly submaximal reticulocyte response in suitable patients. If the unknown substance has suffered significant losses of potency in preparation, a reticulocyte rise will occur when the standard material derived from identical amounts of whole organ is given in the second period. If an increase of potency of the unknown over the standard is anticipated, the standard may be given first for obvious reasons. In this case the absence of a second reticulocyte response calls for a reversal of the order of procedure in another patient (see Figs. 16 and 17).

The establishment of standard preparations for both oral and parenteral administration, which could be supplied on demand to those testing products of any sort, would be a considerable advantage in maintaining the potency of material available for physicians to prescribe for their patients. The practice of describing commercial products only in terms of the original amount of liver, stomach, or other tissue from which each is derived, instead of in terms of the residual amount of active principle, leaves much to be desired. Under this system variations in the potency of different commercial products derived from the same amount of original organ have been shown to exist among substances designed both for oral and for parenteral use.[20 21 22] It is therefore desirable that more critical standards be adopted by the medical profession as the basis for accepting commercial products and for labelling their potency. *It is our belief that the reticulocyte method offers the most convenient basis for such determinations.* The description of the acceptable product should indicate what daily amount is just sufficient to produce a maximal reticulocyte response. This amount of material may not be sufficient for maximal red blood-cell production, nor is it necessarily the proper dosage for all patients. Measurement of the reticulocyte response to the uniform daily administration of the product *does not imply* that it should be given in daily dosage in practice but does provide a practical method of determining the effectiveness of a given product under controlled conditions within a few days. The use of the double reticulocyte response provides a means of comparing the potency of material with a standard preparation in the same individual.

Summary

1. The circumstances resulting in the appearance of increased numbers of reticulocytes in the peripheral blood stream of man have been reviewed.

2. The probable non-specific or "irritant" effects upon reticulocyte production of certain substances not supplying a nutritional deficiency have been discussed with especial reference to potassium arsenite.

3. The physiological reticulocytoses resulting from hæmorrhage, blood destruction, removal of toxic inhibition of the bone-marrow, and the supplying of substances necessary for the normal development of the red cell have been discussed.

4. A description has been given of the use of the reticulocyte reaction as a measure of the physiological activity of the bone-marrow in certain types of anæmia.

5. The characteristics of the physiological reticulocyte reaction and its relationship to an increase of the red blood concentration, particularly in response to the administration of material effective in pernicious anæmia, have been defined. A discussion has been given of the influence upon the reaction of certain modifying factors in respect to the administration of potent material and the reactive state of the patient.

6. The use of the reticulocyte reaction as a test for the potency of therapeutic agents in deficiency anæmias, especially by means of "double" reticulocyte responses, has been described.

Conclusions

Determinations of the percentages of reticulocytes in the peripheral blood are of value in estimating the activity of the bone-marrow. Characteristic increases of reticulocytes in response to the administration of certain therapeutic agents, when properly correlated with increase of the blood values, are useful in the diagnosis of nutritional deficiency anæmias and in the determination of the effectiveness of therapeutic agents. The possibility of non-specific effects, especially with parenterally administered substances, must be kept in mind.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Rapid progress is being made with the appeal for £100,000 for this hospital, and Lord Nuffield has promised to give £25,000 when the city has raised £75,000. Less than £12,000 is now required before he will be asked to fulfil his promise.

EDINBURGH ROYAL INFIRMARY.—A warrant has been granted for the erection of the new residence for the nursing staff of this hospital. It is to be built at the south end of Archibald-place where the entrance to George Watson's College was situated. The building is to be six stories high, and will have accommodation for 280 nurses. Each bedroom is to be furnished with built-in furniture and a wash-hand basin. Adequate bathrooms will be provided, and there are to be two shampoo-rooms on each floor. There are also to be rooms for lectures, studies, and writing. A special feature will be a large recreation-room, measuring 77 feet by 30 feet, which will be in the centre of the building on the ground floor. It is to have two sitting-rooms opening off, one at each end, which are separated from the main room by folding partitions which enable the three rooms to be thrown into one for special functions. The main entrance will be from Archibald-place, and four minor entrances communicate with the hospital. Four electric lifts and five stairways will allow easy exit in case of emergency. The estimated cost of the building is £110,000.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXIV.—PROGNOSIS OF SALPINGITIS

THE peculiar anatomical features, and, perhaps, physiological function of the pelvic peritoneum render the prognosis of suppuration in this region rather different from that of other abdominal abscess formation. The pockets of the pelvis, and probably its more resistant peritoneum, enable infection to be sequestered and pus to be sterilised in many cases of peritonitis which originate from the tubes. Therefore, while there may be no small amount of pelvic invalidism and even acute exacerbation of peritonitis, there is seldom the mortal danger which accompanies abscesses in and around the appendix and gall-bladder.

Non-suppurative Salpingitis

Most cases of acute salpingitis follow gonorrhœa or septic infection at abortion and labour, and, excluding tuberculous infections, there is scarcely any other important cause of salpingitis. The two main varieties of each of these forms are the non-suppurative (or "catarrhal") and the suppurative. The first, or catarrhal variety quickly subsides, leaving no symptoms or physical signs, and may even disappear to such an extent as to leave the tube functionally sound. We are compelled to notice the remarkable powers of complete resolution possessed by the tube because pregnancy has followed undoubted cases of mild salpingitis. The restoration of function obviously depends upon the maintenance of the lumen, and also, we believe, on the integrity of the ciliated epithelium, by which the ovum is propelled towards the uterus. If both ostia are permanently closed the woman must be sterile, and it is probable that any considerable replacement of ciliated epithelium by non-specific epithelium must also be associated with sterility, or what amounts to the same thing—tubal gestation.

Our experience of resolution includes not only cases of the mildest salpingitis which can recover sufficiently to allow a subsequent pregnancy, but even those in which the tubes have been definitely palpable during and immediately after the acute attack. But despite the undoubted occurrence of complete resolution, the fact remains that by reason of its delicate fimbriæ and ciliated epithelium the tube is a vulnerable organ, and its function is easily impaired by the mildest infections. Should the fimbriæ adhere by the most filmy adhesions the orifice will be blocked; and so narrow is the interstitial portion that it must require only the slightest epithelial desquamation to ensure adhesion of the walls and permanent occlusion. We must therefore regard an attack of even mild salpingitis as a serious event in the reproductive life of a woman, which will probably render her permanently sterile. Some months after the attack has cleared up, the functional prognosis can be settled by X ray examination of the pelvis during the injection of lipiodol into the uterus by an intra-uterine syringe. This test will demonstrate effectively not only if the tubes are occluded, but also the site of the occlusion.

IMMEDIATE RESULTS

The immediate prognosis of acute salpingitis is nearly always good, though operation may be necessary for abscess formation or prolonged tubal swelling with continued temperature. The great majority of all gonococcal cases settle down without danger of general peritonitis, but where the tubes become infected after labour the danger of extending peritonitis is greater because, before uterine involution is complete, the tubes are abdominal rather than pelvic organs. Not only is their anatomical situation a potential danger, but the infection may be highly virulent and prone to spread rapidly. In these cases salpingitis is usually only a comparatively minor part of a widespread or generalised infection of far greater importance than the local focus in the tubes. Salpingitis after abortion is less immediately serious as the tubes have not been carried up out of the pelvis by the enlarged uterus, but it is liable to be followed by abscess formation or chronic interstitial salpingitis. The rare occasion on which acute salpingitis follows curettage of the apparently normal but infected uterus is nearly always fatal on account of the severity and rapid spread of the accompanying peritonitis.

LATE RESULTS

The later results which may follow an average attack of acute non-suppurative salpingitis are an important part of the consideration of any given case. The possibilities are: (1) resolution, or, if not complete functional restoration, such disappearance of all active infection as to prevent any further recurrence of signs or symptoms; (2) the formation of a permanently thickened tube with closed abdominal ostium, and containing a small amount of sterile, turbid fluid (interstitial salpingitis); (3) rarely, pyosalpinx or tubo-ovarian abscess of varying size, adhesions, and toxicity; and lastly, (4) hydrosalpinx, which may be a thin-walled sac formed by the tube distended by clear fluid.

The clinical outlook will depend upon the pathological legacy of the acute attack, and to a lesser extent on the manner of life and social status of the patient. Where even mild permanent changes are left, such as thickening of the tube wall, adhesions of the tube, ovary, gut, and uterus, there will be some disability for a varying number of months or years, which will gradually disappear as the tubal condition becomes more and more an obsolete lesion. The disability will take the form of pelvic pain or discomfort caused by fatigue and menstruation. There will probably be some increase of menstrual loss on the first day or two, and leucorrhœa, but on the whole the symptoms are mild and strikingly dependent upon fatigue, overwork, and mental stress. If the woman can live a life of ease she will have little trouble, but if she is a working woman either as the non-salaried, active mistress of her own house and family, or as a regular salaried worker in somebody else's house or factory, she will find that her pelvis is her heel of Achilles. As time goes on, however, and with due care, rest, and symptomatic treatment, the symptoms gradually subside, and the pelvic weakness is forgotten. There is much evidence to this effect to be found during the course of pelvic operations. During laparotomy, done for some other condition, the tubes may be found thickened, closed, and adherent, though there may have been no immediate complaint of pelvic symptoms. The patient has obviously had salpingitis and still carries its final anatomical results, but she has, perhaps, long ceased to know of its existence. The steady, if lengthy, course of improvement is always liable to interruption, however, if the woman is overworked, contracts a "chill" just before or at the beginning of menstruation, or as some evidence shows, develops a severe attack of influenza.

Suppurative Salpingitis

After an attack of true suppurative salpingitis the subsequent course is not so simple. The tube is left as a sealed sac containing pus. The immediate convalescence may require three weeks before the temperature returns to normal, and though the pus may gradually become "sterile" as far as ordinary bacteriological examination can show, yet the patient is very liable, almost inevitably liable, to have repeated exacerbations of symptoms due to recrudescence of local tubal peritonitis. On these occasions the clinical features of the original attack are reproduced, and again one can feel the tender fixed tubal swellings alongside and behind the uterus. Not only will she suffer these repeated attacks of pelvic illness, but during the intervals she will never be really robust and well. She may lose weight and have a toxic appearance, while menstruation will be too frequent, excessive, prolonged, and painful. Secondary conditions, such as anæmia, bacilluria, and metastatic "rheumatic" foci are also possible complications.

PROGNOSIS AFTER OPERATION

While medical treatment will usually succeed in the former group, there is no hope except from operation in the latter group in which "chronic" tubes contain actual pus. It is well, however, to remember that immediate and complete recovery to normal health will not follow the removal of pyosalpinx. If the tubes, and probably infected portions of the ovaries, are alone removed, the patient will certainly lose those symptoms which are the direct outcome of harbouring pus anywhere in the body, but unless the uterus, which is inevitably also infected, congested, and enlarged, is also removed the patient is still left with all the troubles of menstruation and leucorrhœa. It is theoretically conceivable that after the adjacent abscesses have been removed the uterus would gradually return to normal, but in fact the process is either very slow, or else fails entirely, and the patient, even after so remedial an operation as removal of pus sacs, may still find herself a menstrual invalid, with only a few days in the middle of the month of comparatively good health.

Hysterectomy, especially for a young woman, may appear to be too radical, but actually the ultimate results are better, and as the woman would anyhow have been sterile, the operation will not have deprived her of potential child-bearing. If the operator hesitates during the operation, mindful of the youth of his patient, of her recent marriage, maybe, and of the added time and difficulty of hysterectomy—and individual circumstances should always render every decision a special one—he should remember the interstitial portions of the infected tubes, and therefore remove a wedge-shaped piece of the fundus to include them. Convalescence is always prolonged. It may be months, even a year or more before good health is regained. Much, if not all, depends upon how far menstrual symptoms disappear, for it is the oft-recurring depression of health combined with excessive loss of blood which holds her back from complete recovery.

We are often asked about the effect of the operation on *sexual feeling*. Normally, removal of pyosalpinx will not only not depress it, but will actually increase it by improving the general health, but where the ovaries have been sacrificed as a part of suppuration there may be, but by no means necessarily, some gradual fading of sexual feeling. Much depends upon the type of woman. Some women suffer no loss whatever either after the menopause or double oöphorectomy, whereas others find that their sexual life has finished. It is probably safe to say that the outlook in this direction is determined more by the degree of sexual activity and development of the woman than by the surgical deprivation of certain endocrine influences.

INTERNATIONAL NEUROLOGICAL CONGRESS

(*Concluded from p. 269*)

Discussions

THE CEREBRO-SPINAL FLUID

IN opening a discussion on the physiology and pathology of the cerebro-spinal fluid, Dr. L. H. WEED (Baltimore) said that in the developing embryo the appearance of the choroid plexuses corresponded with the extraventricular spread of the cerebro-spinal fluid. Whether the fluid was a true secretion or a filtrate depended upon whether the cells of the choroid plexus did work in its formation. Lewis Flexner's investigations supported the view that the fluid was a secretion. Dr. Weed's own researches had shown that the factors influencing the absorption were the difference between the hydrostatic pressure of the fluid and the sagittal venous pressure, together with the osmotic pressure of the blood. In quadrupeds the hydrostatic factor was small and the major effective force was the osmotic pressure of the blood colloids, which was equivalent to 250 to 300 mm. of saline. The Monro-Kellie doctrine that the volume of the cranial contents was constant, though modified in details, was essentially sound.

Prof. G. SCHALTENBRAND (Würzburg) gave an account of the evolutionary history and the anatomical structure of the choroid plexuses, the leptomeninges, the Virchow-Robin spaces, and the arachnoidal tufts. He showed lantern slides illustrating the microscopical changes in the cells of the choroid plexuses, which were believed to be contemporary with the formation of cerebro-spinal fluid. He described the effect of osmotic changes on the circulation of the fluid.

Mr. HUGH CAIRNS (London) discussed the treatment of hydrocephalus. There were at least eighteen causes of hydrocephalus in infancy and it was obvious that an accurate diagnosis must precede effective treatment. Hydrocephalus in adults might be due to a congenital membrane blocking the foramen of Magendie, incision of which afforded relief. The ætiology of otitic hydrocephalus, which sometimes followed otitis media or mastoiditis, was incompletely understood. It was characterised by an increase in the volume and pressure of the cerebro-spinal fluid in which the protein content and cells were abnormally low. Papillœdema was the most important symptom. The condition subsided spontaneously in time, if the patient were treated with repeated lumbar puncture.

Mr. Cairns also spoke on post-operative hydrocephalus following the removal of a tumour from the posterior fossa, cystic loculations of fluid after removal of intracranial tumours, cerebral œdema, and cerebral shrinkage.

Prof. F. Georgi (Yverdon) dealt with the physico-chemical basis of the formation and resorption of the cerebro-spinal fluid. He emphasised the difficulty of drawing a conclusion from the physical and physico-chemical properties of the fluid and equally from the presence in, or absence from, the fluid of hormones or immune bodies. He thought, however, that a process of simple dialysis could be excluded as the mode of formation of the fluid. Drs. Orzechowski, Boschi, and Zandt also contributed to the discussion.

FUNCTIONS OF THE FRONTAL LOBES

The discussion on the functions of the frontal lobes was opened by Prof. J. A. Barré (Strasbourg). He said that under the name of ataxie frontale Bruns had drawn attention in 1892 to certain disorders of balance in stance and gait which he had observed to be associated with tumours of the frontal lobe and which resembled cerebellar ataxia. The recognition of ataxia as a symptom of a frontal lobe tumour was of value in drawing the attention of the clinician to the need for diagnosing frontal lobe tumour from tumour of the cerebellum. Prof. Barré, however, was critical of Bruns's conception and said that "fronto-cerebellar ataxia" was neither ataxia nor frontal nor cerebellar. He considered that retro- and retro-latero-pulsion were the disorders of equilibrium most characteristic of a frontal lobe lesion, especially when they occurred early. He also discussed the apraxie de marche of Gerstmann and Schilder, which he considered to be a complex psychomotor disorder, the product partly of mental deterioration and partly of astasia-abasia.

Prof. P. Delmas-Marsalet (Bordeaux) also discussed the functions of the frontal lobe in respect of equilibrium. Experimental investigations, he said, yielded evidence that the prefrontal lobe was concerned in coördination. From the clinical standpoint it was possible to recognise four fundamental elements in the symptoms of frontal lobe lesions, a cerebellar disorder, a labyrinthine disorder, an apraxic and an agnosic factor.

Dr. K. Goldstein (New York) referred to the relations between the frontal lobes and the psychic functions. There was ample evidence that lesions of the frontal lobe, especially if they occurred on the left side, were associated with psychic disturbances, which were not necessarily limited to a single mental function. The defect which was found in all functions bore a close relationship to the particular situation which called a particular type of behaviour into play. Psychical symptoms themselves were not sufficient to determine a differential diagnosis. It was not accident that the mimic movements, language and writing, which were of such great social importance, should be represented in a part of the forebrain, near that which was concerned in psychical functions.

Dr. Clovis Vincent (Paris) described the functions of the frontal lobe from the standpoint of the neurosurgeon. He said that in certain conditions partial or total resection of the lobe gave rise to no definite psychical or motor disorders. In the neighbourhood of the third ventricle there was a mechanism whose excitation or paralysis led to a sudden swelling of the frontal lobes brought about by vascular congestion and œdema. Epilepsy, and particularly status epilepticus, might be related to this vascular disturbance in the frontal lobes. Distension of the ventricular system was capable of producing mental symptoms similar to those of a frontal lobe tumour.

Dr. R. M. Brickner (New York) reported his study of a unique patient who had undergone removal of both frontal lobes for meningioma, Broca's area and the motor cortex being left intact. An analysis of the resulting mental disorder supported the view that only one function was impaired—namely, the elaborate association or synthesis into complex structures of the simpler engrammic products associated in the more posterior parts of the brain. Dr. Brickner summed up the functions of the frontal lobes as the production of "ingenuity"; but more than ingenuity was required if man was to achieve a harmonious and intelligent control over his emotions.

THE HYPOTHALAMUS AND CENTRAL REPRESENTATION OF THE AUTONOMIC NERVOUS SYSTEM

The last discussion was opened by Prof. C. U. Ariëns Kappers (Amsterdam), who described the phylogenetic development of the autonomic hypothalamic centres in fishes, amphibia, reptiles, and birds, compared with the lower mammals. The ontogenetic development and normal conditions in man were dealt with by Prof. W. E. le Gros Clark (Oxford).

Prof. J. Lhermitte (Paris), speaking on the anatomo-clinical syndromes of the hypothalamus, said that the neural functions of the hypothalamus were indissolubly linked with the pituitary gland, the posterior or nervous lobe of which was a prolongation of the brain. The question of whether a certain syndrome was hypothalamic or infundibulo-tuberal was identical with the inquiry whether one should seek for the cause of the trouble in the vegetative centres of the hypothalamus or in a primary endocrine disturbance. He reviewed the present state of our knowledge of the anatomy and physiology of the hypothalamus and then described the syndromes which could be attributed to lesions in this region. These were diabetes insipidus; essential polyuria; essential polydipsia; polyphagia; glycosuria; sleep disorders; disorders of the sexual functions; the lipodystrophies; diencephalic obesity; hypophyseal cachexia; disorders of the hæmopoietic functions; diencephalic epilepsy; and disorders of temperature regulation. The pathological disorders responsible for these syndromes included syphilis, tuberculosis, the acute encephalitides, tumours, and hydrocephalus.

Prof. A. W. Adson, of the Mayo Clinic, described the physiological effects produced by ablation of the autonomic central influence by interrupting sympathetic pathways in the treatment of various diseases. He paid especial attention to Raynaud's disease and stated that although the cause of the pathological vasoconstriction had not been settled, observations following sympathetic ganglionectomy, trunk resection, and ramisectomy had strongly suggested a central control. The effect of sympathectomy in the treatment of congenital megacolon, disorders of the bladder, and essential hypertension were also discussed.

Prof. O. Löwenstein (Nyon) reported experimental researches on the manifestation of physical and psychophysical constitution in the vegetative nervous system. By means of cinematographic records he had been able to make a graphic representation of the behaviour of the pupils in various conditions and he exhibited graphs showing the timing of pupillary constriction and dilatation. There were several forms of normal response which he considered to be indicative of psychophysical constitution types.

Prof. Laruelle, Dr. Hirsch, Dr. Spatz, and Prof. Grunstein also took part in the discussion, which was brought to a close by Prof. B. Brouwer (Amsterdam).

Short Papers

Some 250 short papers were presented to the Congress. Epilepsy attracted the greatest interest, since apart from the discussion which occupied the whole of the first day there were over forty papers on this subject. The autonomic nervous system occupied the second place with 27 papers, and intracranial tumours and the surgery of the nervous system came next with 18. It is impossible to report more than a selection of the communications read.

EPILEPSY

Dr. W. G. Lennox (Boston) read a paper on the relationship of unconsciousness in human subjects to cerebral blood flow and to anoxæmia. A study was made of blood leaving the brain in unanæsthetised human subjects with reference to loss of consciousness. These fell into two groups. In one were those in whom the unconsciousness was preceded by a sharp fall in the volume of cerebral blood flow or was accompanied by a very low oxygen saturation of the blood leaving the brain. In the second group were those carotid sinus cases, and one hysterical, which had no preliminary fall in blood pressure. These had a decrease in neither the flow nor the oxygen saturation of the blood leaving the brain. The experiment suggested that even acute cerebral circulatory failure or anoxæmia was not the exclusive explanation of the loss of consciousness but was only a stimulus to a neural mechanism.

Dr. F. A. Gibbs and Dr. E. L. Gibbs (Cambridge, Mass.) described the convulsion threshold of various parts of the cat's brain. Experiments with a needle electrode on 400 cats had shown that not all parts of the cat's brain were equally sensitive to electrical stimulation, and there was evidence that the structure from which convulsions were most readily excited was a short fibre system running between the frontal cortex, basal ganglia, and the thalamus. The conclusion was drawn that convulsions were produced by a specialised neural mechanism in the brain, a mechanism which was at least as well localised as that which controlled dilatation of the pupils.

MM. Pagniez, Plichet, and Laplane (Paris) discussed the rôle of cutaneous parasites in the roduction of experimental epilepsy. They had found that the epilepsy of Brown-Séquard in the guinea-pig depended upon the multiplication at the epileptogenous zone of the neck or face of cutaneous parasites (mallophages), which are normally to be found in all guinea-pigs. The suppression of these parasites led to the complete disappearance of the epilepsy, which recurred on their return. A lesion of the sciatic nerve was in no way necessary for the production of the epilepsy and merely acted by favouring the multiplication of the parasites.

Dr. K. Conrad (Munich) spoke on the rôle of heredity in the ætiology of epilepsy. His study was chiefly concerned with the incidence of epilepsy among uniovular and binovular twins. Seventy per cent. of uniovular twins showed a concordance, as compared with 11·5 per cent. of binovular twins.

X RAY DIAGNOSIS

Recent advances in the radiology of the nervous system were embodied in a series of papers from Prof. E. Moniz's clinic at Lisbon. Prof. Moniz himself read one on angiography in the diagnosis of brain aneurysms and angiomas, and gave an account of the technique necessary to obtain pictures of both the arteries and the veins of the intracranial circulation.—Dr. Luiz Pacheco (Lisbon) described the displacements produced in the cerebral arteries by tumours of the frontal, parietal, and temporal lobes, and Dr. Fernando de Almeida (Lisbon) presented normal arteriograms and phlebograms of the brain.—Dr. A. Lima (Lisbon) spoke on the technique of cerebral angiography.

Dr. E. W. Twining (Manchester) reported on the radiological study of the third ventricle. The methods used had proved valuable, he said, in differentiating supratentorial from intratentorial lesions, in lesions near the chiasma and third ventricle tumours, and in study of the contours of the third ventricle and of pressure effects of the third ventricle upon the sella and chiasma.[1]

Dr. B. G. Ziedses des Plantes (Utrecht) described "planigraphy" and "subtraction," two new radiographic methods applied in neuro-roentgenology. Planigraphy yielded an isolated image of a certain plane of the object, whilst subtraction gave an isolated image of that which at one moment does, and at another moment does not, belong to the image-forming object, for example, a contrast liquid.

THE AUTONOMIC NERVOUS SYSTEM

Dr. A. van Bogaert (Antwerp) reported an experimental study of centres regulating the blood pressure in the floor of the third ventricle. He described the effect of faradic excitation in this region. It was possible to evoke a considerable rise in arterial blood pressure in the excitation of which the suprarenals played a part. At the same time the heart-rate increased at first, but later become slow. These experiments afforded evidence for the existence in the floor of the third ventricle of pressor and inhibitor centres of the cardiovascular system.

Prof. C. H. Frazier and Drs. Bernard Alpers and F. H. Levy (Philadelphia) read a paper on the hypothalamus and temperature regulation. The occurrence of hyperthermia in patients in whom suprasellar cysts had been removed at operation and who died within 48 hours showed that the areas affected are chiefly the substantia grisea of the third ventricle and small portions of the mesial part of the nucleus tubero-mammillaris.

Mr. G. C. Knight (London) speaking on the nervous control of the œsophagus, said that experiment had shown that there was a true intrinsic sphincter at the cardia, which received its sympathetic supply in part at least from the cœliac plexus. Bilateral vagal section produced the X ray appearances and symptoms of achalasia of the cardia. If, however, the sympathetic supply to the cardiac sphincter had been severed, no obstruction at the cardia was caused by vagal section. Experimental achalasia could be relieved by sympathectomy.

Prof. L. Asher (Berne) read a report on the mode of action of the sympathetic and its integrative function. An investigation of the influence of the sympathetic on muscle showed that excitation of these nerves produced restoration after fatigue. The sympathetic impulses acted on the muscle itself and shortened the time necessary for restoration. The resynthesis of phosphagen was increased on the side of the sympathetic stimulation.

DISSEMINATED SCLEROSIS

Dr. Tracy J. Putnam (Boston) read a paper on the pathogenesis of multiple sclerosis. Both multiple sclerosis and acute disseminated encephalomyelitis had been simulated in animals by the use of minute doses of tetanus toxin and more recently by obstruction of cerebral venules. Thrombi and obstructed vessels might be found in the lesions of multiple sclerosis, encephalomyelitis and diffuses clerosis. It was suggested that infectious or other exogenous factors might activate the clotting mechanism to an abnormal degree, causing thrombosis chiefly of cerebral venules and then plaques of demyelination and gliosis.

---

[1] Twining, E. W., and Rowbotham, G. F.: The Lancet, July 20th, 1935, p. 122.

Dr. R. M. Brickner (New York) described the blood esterase changes associated with remission in multiple sclerosis. The serum esterase had been studied during remissions in this disease. The esterase values were not distinctive for multiple sclerosis as such, but it was found that during the active phases of the disease the values were low and during the inactive phases high.

Dr. Arthur Weil (Chicago) discussed the demonstration of endogenous myelolytic (myelin-splitting) substances in nervous diseases. A total of 460 urines was examined for the presence of myelolytic substances. These were absent in 30 normal controls, but present in 59 out of 89 patients with disseminated sclerosis and in 13 out of 16 patients with post-encephalitic parkinsonism.

ACUTE ENCEPHALOMYELITIS

Dr. E. Herman (Warsaw) discussed clinical considerations in epidemic disseminated encephalomyelitis, on a basis of 100 cases observed in Poland between 1927 and 1935. A variety of forms of the disease were described according to whether its main incidence lay upon the meninges, nerve roots, peripheral nerves, sympathetic nervous system, spinal cord, medulla, cerebral hemispheres, or psychical functions. In spite of some resemblance both to encephalitis lethargica and to disseminated sclerosis Dr. Herman regards it as a distinct nosological and epidemiological entity.

Prof. A. Austregesilo (Rio de Janeiro) spoke on acute and subacute epidemic neuromyelitis observed in Brazil. Five principal varieties, he said, had been observed: a form with a polyneuritic onset followed by remission and later aggravation; a form characterised by acute neuromyelitis, with fever and symptoms of meningoencephalitis; a severe and fatal form of Landry's paralysis; a severe but completely recoverable form of Landry's paralysis; and a form of acute neuromyelitis of the Landry type but terminating in myelitis. It was believed that a new virus was responsible for the malady.

THE SURGICAL TREATMENT OF HYPERTENSION

Prof. Max M. Peet (Ann Arbor, Michigan) reported the results of operations upon 60 patients with hypertension. The surgical procedure consisted of bilateral resection of the greater and lesser splanchnic nerves and of the lower dorsal sympathetic chain, usually including the 10th, 11th, and 12th dorsal ganglia. The blood pressure of all patients operated upon was over 200 mm. of mercury, and many showed retinal hæmorrhages and exudation with papillœdema. Some degree of improvement was seen in 85 per cent., and in 15 per cent. this amounted to apparent cure; 10 per cent. were not benefited. In some cases the blood pressure, previously as high as 285 mm. of mercury, remained at 130 or 140 over periods ranging from six to seventeen months. Papillœdema, retinal hæmorrhages and exudate disappeared and there was a complete return to normal vision and renal function.

Prof. Adson (Mayo Clinic) described the results obtained in 32 cases. He had found that bilateral ventral rhizotomy through a laminectomy wound from the 6th thoracic to the 2nd lumbar roots inclusive was more effective than bilateral resection of the splanchnic nerves. The mean drop in systolic pressure after extensive rhizotomy was 44 mm. of mercury and the mean drop in diastolic pressure was 38 mm. The patients who responded best to this treatment were those whose symptoms of hypertension were progressive but whose disease had not done irreparable damage to the heart, kidneys, or retinal and cerebral vessels.

Prof. Pavlov's Address

Prof. I. P. Pavlov, speaking in German, read before a crowded audience a paper on "the types of higher nervous activity, their relation with the neuroses and psychoses, and the physiological mechanism of neurotic and psychotic symptoms." On the basis of his experiments on conditioned reflexes, Prof. Pavlov said it was possible to distinguish four types of dog. According to the strength of the excitation processes the dogs could be divided into two groups, the weak and the strong. The strong could be further subdivided according to the relationship between their excitation and inhibition processes into the balanced and the unbalanced, and finally the strong balanced type could be divided according to the liveliness and lability of the nerve processes into the slow and the quick. Thus the four types were, the strong unbridled, the strong balanced and slow, the strong balanced and quick, and the weak. These corresponded to the four Greek temperaments, the choleric, the phlegmatic, the sanguine, and the melancholic. In order to explain the normal and the pathological conduct of man it was necessary to add to these types which were common to man and animal, special human types, the artistic, the thinking, and an intermediate type. Under experimental conditions neuroses arose readily in the excitable, unbridled, and in the weak type of dog. The former lost almost entirely the capacity for inhibition: in the latter the higher nervous activity either failed entirely or remained in a chaotic state. Kretschmer, who limited himself to two general types, the unbridled and the weak, appeared to relate the former type with manic-depressive psychosis and the latter with schizophrenia.

Prof. Pavlov considered that constitutional neurasthenia was the characteristic disorder of the general weak or unbridled type and of the intermediate human type. Hysteria is the product of the general weak combined with the artistic type, and Janet's psychasthenia the product of the combination of the general weak with the thinking type. Weakness of the excitation processes led to predominance of the inhibition processes in the form of sleep and hypnotic conditions, and a similar explanation was offered for narcolepsy, cataplexy, catalepsy, and catatonia.

Hughlings Jackson Lecture

The Hughlings Jackson lecture, entitled The Motor Cortex in Man in the Light of Hughlings Jackson's Doctrines, was delivered by Prof. Otfrid Foerster, of Breslau, at a special meeting of the neurological section of the Royal Society of Medicine before an audience drawn from neurologists of all nations assembled in London for the Second International Congress of Neurology.

Dr. S. A. Kinnier Wilson, president of the section, after recalling the distinguished neurologists who had previously delivered the Hughlings Jackson lecture, explained that the lecture had been arranged to coincide with the meeting of the Congress as a fitting celebration of the centenary of Hughlings Jackson's birth.

Prof. **FOERSTER** expressed his appreciation of the honour conferred upon him in being asked to deliver the lecture in the year of Hughlings Jackson's centenary, and of the opportunity it afforded him of paying a tribute to Hughlings Jackson in the place where he had carried out the work which constituted "monumentum aere perennius."

Jackson was the first to point out the existence of a motor cortex, his recognition of which was based upon the experiments on the human brain conducted by disease. He recognised that epileptic convulsions were a caricature of movements and from this he derived the revolutionary view that the cortical motor cells must be concerned with movement. Jackson's localisation of foci in the motor cortex, based upon clinical observation, alone remained unchanged to-day. Prof. Foerster discussed the significance of the bilateral representation of certain movements in the motor cortex and said that in the case of these movements bilateral effects could still be obtained from electrical excitation of the motor cortex after division of the corpus callosum. Movements were not represented in the motor cortex in sharply delimited areas. Repeated electrical stimulation of a single area might be followed by movements of different though closely associated limb segments. The motor cortex, in fact, was not a mosaic like a cubist picture but more closely resembled the soft and merging colours of a Raphael Madonna.

As a result of the localisation of motor functions in the motor cortex localised lesions in this region produced focal palsies, examples of which were given. The precentral convolution had been subdivided by Brodmann into two areas, area 4 and area 6 aα on the basis of differences in the size of the ganglion cells. An English neurologist had recently expressed the opinion that this anatomical difference was not correlated with any difference of function, a view which would not have been acceptable to Hughlings Jackson and was in conflict with the fundamental work of the Vogts and Fulton. Electrical stimulation confirmed the difference of function between these two areas and there was evidence that the motor effects of area 6 aα were mediated through area 4, for after excision of area 4 area 6 aα was no longer excitable.

In Jackson's view no cortical area was purely motor and none was purely sensory. Though the postcentral convolution was an important sensory area, when stimulated electrically it yielded the same movements as the precentral convolution, though the threshold was higher. The aura of a convulsion originating in the postcentral convolution was a sensory disturbance.

Prof. Foerster described the features of the convulsions excited by stimulation of other regions of the cerebral cortex. Severe vertigo occurred as a manifestation of an irritative lesion of the interparietal sulcus. From motor areas other than the precentral convolution complex postures and movements could be excited. Such excitable areas utilised extrapyramidal paths and were the means by which were mediated the clumsy synergic movements of the whole limb which remained after destruction of the pyramidal tract. After such a lesion improvement in skilled movements might occur through the compensating function of the undamaged ipsilateral motor cortex, but such compensation was never complete. After excision of an area of extrapyramidal motor cortex, motor symptoms were absent or transitory. The isolated destruction of area 4 or of area 6 aα, the results of which had been so carefully analysed by Fulton in the primates, was very rare in man.

There was scarcely a single neurological problem which had not been illuminated by Hughlings Jackson's ingenuity. It had been said that, except the blind forces of nature, nothing moved in this world which was not Greek in origin, and it was true to say that nothing moved in neurology which was not in origin Jacksonian.

After Dr. **KINNIER WILSON** had presented Prof. Foerster with the Hughlings Jackson medal, Prof. **VIGGO CHRISTIANSEN**, Prof. **G. MARINESCO** (*in absentia*), Prof. **MAX NONNE**, and Prof. **PAVLOV** were admitted as honorary members of the neurological section of the Royal Society of Medicine.

Social Functions

His Majesty's Government gave a reception to members of the Congress at Lancaster House on Monday, July 29th, when the members were received by Sir Kingsley Wood, Minister of Health, and Lady Wood. On Tuesday receptions were held at the Royal Colleges of Physicians and Surgeons, where members were received by the presidents, Lord Dawson of Penn and Sir Cuthbert Wallace. On Thursday the official banquet of the Congress was held at the Grosvenor Hotel. Dr. Gordon Holmes presided and the toast of the International Congress was proposed by Lord Dawson and responded to by Prof. Kroll on behalf of Prof. Pavlov, Dr. Bernard Sachs, Prof. Claude, Prof. Nonne, and Prof. Christiansen. The toast of the officials was proposed by Prof. Monrad-Krohn and responded to by Dr. Kinnier Wilson. On Friday a reception was held at the Royal Society of Medicine, the guests being received by the immediate past-president, Mr. Warren Low. A cinema entertainment was given. The beautiful weather added much to the pleasure of the meeting and especially the excursions to Oxford, Cambridge, and other places of interest in and around London.

The arrangements for the Congress were in the hands of Dr. Gordon Holmes, president; Dr. S. A. Kinnier Wilson, secretary-general; Dr. Anthony Feiling, treasurer; and Dr. Macdonald Critchley and Dr. E. A. Carmichael, assistant secretaries. Mrs. Wilfred Harris was chairman of the ladies' committee, of which Mrs. Gordon Holmes and Mrs. Kinnier Wilson were secretaries.

PARIS

(FROM OUR OWN CORRESPONDENT)

TYPHOID FEVER AND SHELL-FISH

WITH the notification of typhoid fever little more than a pious ideal, it is notoriously difficult to obtain reliable figures about the morbidity from this disease in France. Mortality returns are nearer the truth, witness the paradox that in certain areas the death-rate exceeds the sickness-rate from the enteric fevers. Since 1925 the *Bulletin de la Statistique Générale de la France* has been publishing mortality returns of which Dr. G. Dubreuil has recently made good use. His main points are that the enteric fevers are more common in seaboard than in inland areas, that the *fruits de la mer*—i.e., shell-fish and the like—are out and away their most serious cause, and that the comparatively small communities living on the sale of these fruits are at present disregarding public health measures at the expense of vast numbers of consumers These pay with their lives for the immunity enjoyed by a minority to poison them. As Dr. Dubreuil caustically remarks: "It seems to me that those who speak in favour of the living producers might be confronted with the representatives of the dead consumers. For though the latter no longer vote, they have at least a consultative voice." Dr. Dubreuil's figures deal with the seven-year period 1925–1931, and show that the average annual death-rate from typhoid and paratyphoid fever throughout France was 4·8 per 100,000 inhabitants; the department of Bouches-du-Rhône heads the list with 16·2 deaths per 100,000. Of the 23 departments with a typhoid mortality above the average, only 7 were inland departments; whereas of the 67 departments enjoying a typhoid mortality below the average, only 9 were seaboard departments. Of the 66 inland departments, as many as 57 had a typhoid mortality below the average. In his study of the four principal zones of endemic typhoid fever, Dr. Dubreuil gives due credit to defective drainage and water-supplies, milk and its products, and raw fruits and vegetables as causes of the enteric diseases; but he comes back to the *fruits de la mer* as the crux of the problem.

PIRQUET TESTING OF RECRUITS

There is this to be said against Pirquet surveys of students, hospital patients, and other more or less isolated units, that the findings are applicable only to a limited class. A conscript army, on the other hand, with its deliberate disregard of social and economic strata of society, offers opportunities for investigations whose conclusions hold good for the entire population at a certain age. A recent Pirquet survey has been presented by Dr. J. Troisier, Dr. M. Bariéty, and Dr. P. Nico to the Academy of Medicine (Bull., 1935, cxiv., 54); their material consisted of infantry recruits, aged 20 and 21, combed out from all the social classes of northern and eastern France. Some came from the country, others from large towns. In as great a proportion as 25 per cent. the reaction was definitely negative, and only in 60·6 per cent. was the reaction definitely positive. These findings, confirmed in many other countries, suggest that the teaching of yesterday, that nearly every member of a civilised community is Pirquet-positive before adult life is reached, is incorrect or out of date. If it is incorrect, then we have been misled into applying to the world at large the findings of tuberculin surveys in hospital and urban milieux in such towns as Vienna. If, however, this teaching is out of date, and what was true a score of years ago is no longer true to-day, then we seem to be approaching a time when, with many if not most of our young adults tuberculin-negative, we must think of them in terms of susceptible natives hailing from distant shores whose soil is virgin. As the military investigations just quoted show, the percentage of negative reactors is much higher among young rural than young urban members of the community; and now that the pendulum is swinging in favour of regarding the young tuberculin-positive adult as more tuberculosis-resistant than the young tuberculin-negative adult, the centre of gravity of the problem is shifting from the town to the country. If something has to be done for the rural aspirant to army or city life, the thoughts of Frenchmen to-day naturally turn to B C G inoculation of the tuberculin-negative.

THE EXAMPLE OF BREST

And recent experience at a naval port points in the same direction. The port of Brest is one of the black spots on the tuberculosis map of France. Officially, and during the past ten years, the annual death-rate there from tuberculosis has been 5·3 per 1000. More than every fourth death is officially traced to tuberculosis. But with the official notification of tuberculosis as a cause of death notoriously incomplete, these figures are an under-estimate. More instructive is the observation that, for the whole of France, the tuberculosis death-rate is about 1·6 per 1000 annually, or less than one-third that of Brest. Faced by this serious state of affairs, Dr. J. Quérangal des Essart, chief medical officer of the 2nd Arrondissement Maritime of Brest, has, since 1926, sought to reduce the morbidity and mortality from tuberculosis by systematic B C G vaccination of infants and tuberculin-negative children and young adults, and in coöperation with Mme G. de Carbonnières de Saint-Brice he has now published (Rev. de la Tuberc., June, 1935) studies of 823 families with a total of 2277 children, 1193 of whom were given B C G by the mouth at birth in three doses, while the others served as controls. Other children were given B C G by subcutaneous injection. The presentation of their results leaves much to be desired, but it seems pretty clear that the mortality among the controls was much higher than among the children who had B C G.

DEATH OF A CENTENARIAN

The death on July 16th of Prof. Alexandre Guéniot has shocked Paris into realising that even centenarians are mortal. Ever since November, 1932, when he celebrated his 100th birthday, his alert and cheerful personality had captured the imagination of his compatriots who had come to regard him as the personification of the most vital qualities of the typical Frenchman. A much interviewed man, he was generous in parting with the secrets of his long life. They were simple enough in all conscience. No asceticism but moderation, moderation in all things. Caution also was one of his watchwords. Before you cross a road, look to right and left and then to left and right. He applied this advice to his own conduct both metaphorically and literally. His career was distinguished. In 1863 he was appointed to an obstetrical hospital in Paris, and in 1869 the title of professor was conferred on him. He was president of several important societies including the Obstetrical Association and the Academy of Medicine. Most of his publications from 1860 onwards dealt with gynæcological subjects.

TOLL OF THE ROADS

Dr. Béhague has described the organisation of first aid on the French highways—a system for whose creation he is largely responsible; there are now more than 2000 first-aid posts on the highways, and they treat an imposing number of casualties. There are, according to Dr. Béhague, three particularly dangerous hours. Between 11 and 12 road accidents are common because the meal ahead makes the driver accelerate. Between 3 and 4 he is again liable to accidents because the meal to which he has hurried has rendered him drowsy and, if alcoholic, it has also impaired his judgment. There is a third accident peak at 6, when workers leave the factory and scurry off on bicycles on which they collide with motor-cars. But the motor-bicycle is the supreme generator of road tragedies. Absolutely the number of road accidents continues to show an upward curve, but relative to the number of vehicles there has been a progressive decline since 1932, the happy result of a combination of factors—better roads, better cars, better signals, and better drivers, for 35–40 per cent. of those who would like to drive are eliminated by failure to satisfy the examiners for licences. Dr. Béhague lays great stress on the educational measures designed to create a healthy fear of motor vehicles in the minds of the younger generation; he notes that dogs and chickens are less vulnerable than they used to be, having educated themselves. But how he does not explain.

BUCHAREST

(FROM OUR OWN CORRESPONDENT)

AN ACADEMY OF MEDICAL SCIENCES

A LONG-FELT want is met by the establishment of the new Rumanian Academy of Medical Sciences, whose object is the furtherance of medical, veterinary, and pharmaceutical knowledge. For the time being it will have only 32 members, nominated by the medical, veterinary, and pharmaceutical faculties of the universities. The Bucharest medical faculty is represented by Profs. Anghelescu, Balacescu, Danielopolu, Marinescu, Parhon, Proca, and Rainer. At the first meeting, held on July 1st, the members elected Prof. Anghelescu, the present minister of education, as their president, and Marinescu their vice-president. Meetings will be held twice monthly in Bucharest, and from the beginning of next year the Academy will publish a periodical of its own with the title *Buletinul Academiei.* At the meeting on July 15th six honorary members were appointed on the recommendation of a committee, which was asked to submit the names of six illustrious foreign professors who have some connexion with the advance of Rumanian medical sciences. They are Profs. Charles Achard, Henri Vaquez, Emile Sergent, Henri Hartmann, Jean-Louis Faure, and Gustave Roussy. The Academy is to be formally opened, in the presence of many foreign medical celebrities, on Nov. 1st.

PROF. MARINESCU RETIRES

The doyen of Rumanian neurology, the greatest living Rumanian medical scientist, Prof. Marinescu, is to retire on reaching the age limit. His successor will be Dr. Paulian, director of the Central Neurological and Psychiatric Hospital. Paulian is a pioneer of modern neurology and has just returned from lecturing in France, where he has been received with sympathy and approbation. He will be a great gain to the medical faculty, for he is an indefatigable worker in what bears on the social aspect of medicine.

RACIAL PRIVILEGES

In the past academic year there have been frequent disturbances, very often with anti-Semitic tendency, especially in the medical faculty of Bucharest University. So serious did things become that the university board had to fall back on closing the gates of the faculty a month before the Easter holidays. Seeing that this measure did not put an end to the excesses, the board called a conference with the object of making drastic decrees for the restoration of order. This conference strongly condemned the attitude of the students and resolved to deal with them firmly in the future. At the same time it acknowledged, in principle, that limitation of the number of medical students would not be out of place. Selection is necessary, though not on religious or racial grounds, and a committee has been appointed to arrange for examinations to be passed before matriculation. Meanwhile there is a widespread movement, started by M. Vaida-Voevod, the late *Prime Minister*, which demands the protection of the racially Rumanian elements by securing them an 80 per cent. representation in industry, in trade, and also in the so-called free occupations, such as medicine and the law. Thanks to the sane outlook of the present government, Vaida has failed to gain enough adherents to bring his policy into effect, but it has nevertheless stirred up feeling, and even local medical societies have urged that 80 per cent. of State and official positions shall be held by ethnical Rumanians. In these circumstances Prof. Ghiulea of Cluj University, a renowned sociologist, has pointed out that according to the laws at present in force it is not permissible for the universities as a whole to limit enrolment: only the single faculties have the right to fix the number of students. On the other hand, he says, nobody has a right to forbid a citizen from taking his share of education, and from this point of view the suggested limitation is directed against the universal human culture—a proposal the less understandable, because no serious ground for the limitation or reduction of the number of students can be found. At the University of Cluj the number of the Rumanian elements dwindles from year to year, in comparison with the minorities. This phenomenon is not attributable to the increase of the number of minority students but to the pauperisation of the Rumanian elements. The government, in Prof. Ghiulea's opinion, has not solved the problem by excluding the minorities from the high-school education under the "numerus clausus" (as it is called here), which means that the minorities can enrol to the high schools only in the proportion of their census numbers to the general population. The minorities go away to foreign universities and return with first-class qualifications. The "numerus clausus" cannot be a serious solution; results can be attained in this sphere only by complete liberation of education, coupled with support for the Rumanian elements. We have no right to close the gates of the universities to the minorities, concluded Prof. Ghiulea, and thereby exclude them from the boons of culture. The country needs enlightened men and not half-cultivated or uncultivated ones.

COMPULSORY MEDICAL WORK IN THE COUNTRY

Hitherto the supply of doctors to the Bulgarian rural population has been very insufficient. Three-quarters of the physicians live in towns and cities, while three-quarters of the population live in villages. Outside the towns life is so primitive that a man with university education, be he ever so little pretentious, can only put up with it at great self-sacrifice. The Bulgarian government is trying to remedy the present state of affairs—in which there is only one doctor for every 8000 people in the country—by a modification of the public health laws. The new law, which has been recently sanctioned, prescribes two years' compulsory medical service in villages. Any duly qualified physician, who after his graduation has spent a year either at a clinic or in a State hospital, is entitled to carry on practice in a village, and none is allowed to settle in a town unless he can produce a certificate of having spent two years in a village. The board of public health has compiled a list of all the better-class villages where rural practice can be carried on. The villages in their turn are obliged to supply the doctors with adequate houses, while the State pays them 2000 levas monthly. Where the doctor will be called to outside areas he has to be provided with a suitable car. The physicians are obliged to treat poor patients free, but only in their surgeries. The outside fees fixed by the government are quite acceptable: thus a visit to the patient's house is reckoned at 4 shillings, and an intravenous injection at 2 shillings.

MEDICINE AND THE LAW

Damages for Shortened Life

If a man is injured by somebody's negligence and dies of the injury, certain claims for damages which formerly died with him will nowadays survive for the benefit of his estate. This is due to the Law Reform (Miscellaneous Provisions) Act, passed last year. If the injured man lived, he would be able to recover damages for the pain and suffering inflicted by the accident and for the diminution of his normal expectation of life. Under the new law these two claims survive after his death, but an important decision last week (in Slater *v.* Spreag) shows how the new law may be restricted. Mr. Slater was a chimney sweep and gardener, earning £5 a week on the average. Cycling on the Great North Road, he was struck by the defendant's motor-car; his skull was fractured and he died two days later. At the trial the defendant admitted negligence and the case was fought on the issue of damages. Even under the former law Mr. Slater's widow (who was also his administratrix) could have recovered certain limited sums. Under the new law she asked for additional damages for the pain and suffering caused to her husband by the accident and for the diminished expectation of his life. He was 44 years old and in excellent health previously. But he had been unconscious from the moment of his accident until he died. It could not be proved that he had suffered pain; so here was an element of damages which did not exist for him and could not survive for the benefit of his estate and his widow. For the same reason his shortened expectation of life gave his estate nothing to sue upon. In Mr. Justice MacKinnon's view the new law here takes into account only the subjective effect on the injured man, the mental effect upon him of his knowing that his life was cut short. If Mr. Slater never regained consciousness, he never knew of his diminished expectation. There never existed for him on this ground any mental distress which at his death could be cashed for the benefit of his estate. In an easily imaginable case, where an injured man lives on for six months in pain and sees his death approaching him untimely, his right of damages in these respects can survive his death; in Mr. Slater's case there was no claim which could survive. The widow, however, obtained damages on other grounds available under the old law.

Thus the new Act is being gradually elucidated. It has been argued with force that damages are compensation to be paid to a man for injuries suffered by him and that it is impossible to assess the damages to be awarded to one man for injuries sustained by another. How, it is asked, can a man's estate reasonably be compensated if he suffers pain before death? If, to quote the familiar argument usually advanced in these cases, a man bequeaths his estate to the British Museum, how can the institution be compensated for the sufferings which caused his death? The more his life is shortened, the better for the institution. What passes to the executors is not an accrued claim for damages, but merely a right of action; damages cannot be assessed after a man's death on the assumption that he is still alive. Be these metaphysical speculations as they may, Parliament passed the new law and the judges have to make the best of it they can. This was the first time the point has been taken in the London courts. In one case at assizes, Mr. Justice Humphreys has awarded an executor damages for the pain and suffering of the deceased; in another case at assizes Mr. Justice Macnaghten refused to do so. Earlier this year (in Flint *v.* Lovell) the Court of Appeal held that damages at common law, awarded to a man still living, might include a sum for the shortened expectation of life caused by the defendant's negligence. But critics insist that the doctrine of damages for shortened expectation of life cannot reasonably be applied to cases where life has already been shortened by death.

Hearsay Evidence at Inquest

At an inquest last week counsel, appearing for one of the parties possibly concerned, made a protest against the admission of hearsay evidence and even (according to newspaper reports of the case) threatened the coroner with a prerogative writ of some kind for the latitude with which the witnesses were treated. Barristers, accustomed to the strict rules of evidence observed in the regular courts of civil and criminal jurisdiction, naturally and properly take points in the interests of their clients at coroner's inquests; but it is hardly necessary now to say that a coroner is fettered by no rigid rules of evidence. He is bound, as Mr. Justice Wills explained in 1890 when charging the grand jury in a murder case at Chester assizes, to collect as far as he can all information and knowledge of disasters from neighbours and others who can throw any light upon the cause of death; he can often collect facts and statements, which, whether or not they can ultimately be turned into evidence against persons to be put upon their trial, are valuable "as supplying material for investigation by the police and as affording clues which may lead to successful inquiry." If, said Mr. Justice Wills, the coroner rejected evidence on the supposition that he was in the same position as a judge trying a prisoner, he would throw away a good deal of the remaining usefulness of the institution of the inquest. The committee which is at present considering the possible revision of the law and practice of coroners is hardly likely to overlook this aspect.

Two further considerations are not to be forgotten. First, strict rules of evidence largely depend on relevance. A definite person is accused of a definite offence on a definite date; thereupon the witnesses are directed to the proper end as it were along tramlines. At an inquest all is vague; it may be uncertain whether any offence has been committed and whether any specific person was concerned; hence, instead of moving along direct lines to a well-defined object, inquiry roves tentatively in all directions. It is the function of the coroner to range widely, though, where any person is incriminated before him on evidence which is strictly irregular, he will usually advise the jury to dismiss from their minds the inadmissible testimony before committing anyone for trial. In the second place the barrister, who seeks to impose on all tribunals the highly technical rules of procedure in which he has been trained, has no right to take part in an inquest or to put questions or make speeches save by permission of the coroner. Here again there is no analogy between a coroner's court and an ordinary criminal trial, though here again the coroner exercises a discretion which usually satisfies the Bar.

THE THIRD EUROPEAN REUNION OF MENTAL HYGIENE

This congress took place at Brussels on July 20th and 21st, under the auspices of the Belgian National Council for Mental Hygiene. The president was Dr. Ernest de Craene, and the general secretary Prof. G. Vermeylen, both of the University of Brussels. The meetings were well attended and included representatives from Australia, Canada, U.S.A., France, Finland, Holland, Italy, Switzerland, Esthonia, Belgium and Great Britain. The British Government were represented by Sir Laurence Brock, C.B.E., chairman, and Sir Hubert Bond, senior commissioner of the Board of Control. The National Council for Mental Hygiene for Great Britain was represented by Dr. H. Crichton-Miller, Dr. J. R. Rees, and Dr. Doris Odlum. Other British members present were Dr. E. A. Bennett (London), Dr. Mary Luff (London), and Dr. Hemingway Rees (London).

BOARDING-OUT OF MENTAL PATIENTS

In opening the discussion on the first subject, the boarding-out of mental patients in families other than their own, Prof. G. Corberi (Milan) said that this method had only been used in Italy since 1900. The chief reason for its trial had been the necessity of relieving the mental hospitals which were aiming at separating the treatment of those patients suffering from acute and chronic forms of mental illness. In Italy, the foster-families were mostly peasants living in the neighbourhood of a hospital. Since the war there had been a gradual reduction in the numbers boarded out, which was attributable to the recognition of the value of occupation therapy carried out under direct medical control. At Imola, a new system had developed on the ruins of the old. It consisted of the formation of little colonies of patients in the care of peasant families, both colonies and families working under the control of an organisation which dealt with all the needs of the patients, and was responsible for paying the foster-families. At the present time about 10 per cent. of the mental patients from the provincial hospital of Imola were cared for in this way, the cost being halved. He was convinced that this method of treatment was capable of considerable extension.

Dr. Sano (Gheel) said that Gheel was in the peculiar position of having centuries of tradition in the boarding-out and treatment of mental patients. There was a small central hospital to which patients could be sent if they proved unsuitable for family care, and should this condition persist, they would be transferred to one of the State mental hospitals. The difficulty of finding suitable and willing foster-families was one of the greatest drawbacks in places which had not the traditions of Gheel.

Dr. J. Vié (France) spoke of the conditions at the colony of Ainay-le-Château, and discussed the type of mental illness most suitable for care in a colony of the type of Gheel. The medical indications for such treatment depended very largely upon the type of family that would receive patients. Its true function, he said, was a form of social psychotherapy—a readaptation to the life of a household, without emotional stresses, and of a simple character associated with the curative effects of occupation. He thought that, as at Gheel, patients of varying social classes should be part of the system.

In the course of discussion, Sir Laurence Brock said that the experiment of boarding-out the more chronic case, in order to relieve the pressure on the mental hospital, and also to afford the patients themselves some measure of normal home life, was now being attempted in England and Wales. Up to the present, the difficulties had been, primarily, in finding suitable homes. Very few people were willing to take such patients, except those living in rural areas, notably in Suffolk and Wiltshire, and in very poor circumstances. In addition to the difficulty of finding suitable homes, there was the question of keeping the male patients out of public houses. He himself was convinced of the value of this system to the patients, but it was not likely to provide any appreciable saving in the expense of maintenance. If the system were extended to the recoverable case, it might well accelerate their restoration to health in suitable cases.

Prof. Corberi, in summing up, pointed out that at Gheel acute cases were frequently boarded-out, often without any preliminary hospital treatment. He favoured the procedure of treating the acute case in hospitals and only the chronic case placed in a family.

PUNISHMENTS AND RESTRICTIONS

With Sir Hubert Bond in the chair, Dr. H. Meng (Basle) opened the discussion on the psychological value and dangers of punishment and restrictions in the upbringing of the child. He spoke from the psychoanalytic angle, basing the use of punishment and restrictions on a fundamental desire for the control of others which exists in every human being. He held that all punishments and restrictions should aim at bringing the aggressive tendencies of the child under the control of a strong ego. Perhaps one of the most valuable contributions of psycho-analysis to public health lay in its revelation of the true emotional interactions between parents and children. All educational methods should be examined from the point of view of their present and future effectiveness in controlling the aggressive and sexual instincts of the child, so that he might become a productive and coöperative member of the community.

Dr. H. Crichton-Miller stressed the importance of the family and the school as the essential agents of social adaptation. Personal discipline and active social coöperation were the final aim of all educational systems. Dr. Crichton-Miller agreed that the adult desire for vengeance as a basis of the infliction of punishment and restrictions was worthy of investigation, but he did not feel that it was the fundamental problem. Punishment, in his view, had been employed in every stage of society in order to control the child's tendencies to aggression and disobedience, and to combat his destructive instincts. The basic duty of the adult was to adapt the child to life with a minimum of suffering, on a basis of establishing emotional conditioned reflexes. The stress on the vengeance aspect of punishment he regarded as a characteristic error of the Freudian school of thought. In the process of adaptation to life, it was desirable that the child should be surrounded by controlling forces, which in their impersonality and inexorability should appear to him to approach as closely as possible to the laws of nature. The adult who used his desire for power tended to be arbitrary and autocratic, and therefore to destroy the child's sense of emotional security. It was essential that the child should be able to foresee what the emotional attitude of parents or teachers would be to its behaviour, otherwise it would develop a sense of anxiety, discouragement and insecurity. Even the bitter resentment that an over strict régime would provoke, was less damaging than such a feeling of insecurity. Many people condemned all punishments, saying that they believed in controlling by love. The great danger of this attitude was the development of a personal attachment, which was hostile to real freedom. The ideal formula for the child should be "I shall do this in order that I may become a man and independent; if I do not do this, I shall suffer from the opposition of society." The too-strict father replaced it by this formula: "I shall do this to avoid punishment," and the mother, who traded on the child's affection for her, substituted the formula: "I shall do this, or mother will not love me." Of these, the last was obviously the most dangerous; in both cases the child would not develop his personality, but would be influenced rather by the desire to escape discomfort. Though punishments and restrictions had a certain value in the early stages of education they could not in themselves produce a positive attitude of mind, which should be the aim of all education.

In the course of discussion, Sir LAURENCE BROCK spoke as the father of a family, who believed that the ordinary normal child was all the better for a certain amount of punishment and restriction, provided that these were justly administered.—Dr. ODLUM agreed with Dr. Crichton-Miller that nothing was worse for a child than to feel emotionally insecure. Children were, so to speak, emotional barometers where the adults around them were concerned.—Dr. O. L. FOREL (Geneva) agreed that a discipline founded on the desire to render the child an independent personality was the ideal of all education. The actual method was of less importance than the spirit which actuated it.

MENTAL HYGIENE AND THE PRESS

Dr. FOREL spoke of the importance of the Press in influencing the psychology of the people. He was particularly opposed to the publication of reports of suicides, and to advertisements of certain types of drug. Law reports of unsavoury cases and obscene pictures were calculated to undermine public morality. He considered that it would be valuable if each paper could have attached to it a critic competent to assess the mental hygiene value of news.—Dr. J. VAN DER SPEK (Holland) emphasised the suggestibility of the public. Even the more highly educated were greatly influenced by the attitude of their favourite publication. The Press was one of the greatest forces in the world for good or evil.

At the conclusion of the congress the Belgian Council for Mental Hygiene were thanked for their kindness and hospitality. On behalf of the National Council of Mental Hygiene of Great Britain, Sir Laurence Brock and Dr. Odlum invited the members to hold the fourth European reunion in London, in July, 1937.

PUBLIC HEALTH

Food

THE war taught the peoples of Europe that the organisation of national food-supplies was possible. The depression has sharpened their interest in nutrition. Remembering the anxieties of war-time they have expected manifestations of under-nourishment among the families of the unemployed, or the partially employed, and have planned to prevent underfeeding especially of the children. As the result of mass experiments and surveys more is known about the state of nutrition of communities all over the world than ever before, and the effect of supplementation of diets or deprivation of certain food constituents has been widely studied. The remarkable fact has been established beyond question that, in a period of almost unprecedented world depression, the physique of the children of the poor is improving. It is difficult to attribute the phenomenon to anything but intelligent application of the rapidly increasing knowledge scientifically acquired as to foods and feeding, together with a humane attitude toward questions of financial assistance of the poor. Interest in the subject, in spite of the demonstrable improvement, shows no sign of abatement. Indeed, from the feeling that little new remains to be done about the prevention of communicable disease in temperate lands—unless methods of immunisation are simplified and perfected and welcomed by the public—health departments are becoming more physiological and less pathological in their outlook. It seems clear that the promotion of physical and mental fitness, which was the object of the establishment of school medical and maternity and child welfare services some thirty years ago, must absorb the attention of medical officers in public health departments to an increasing extent, and nutrition is at the root of these problems.

A WORLD SURVEY

Recently we drew attention to a summary of present-day knowledge on foods and nutrition prepared in the Health Department of Glasgow.[1] There now comes to hand a broader survey of the subject, prepared by Et. Burnet and W. R. Aykroyd at the instance of the Health Organisation of the League of Nations,[2] addressed to public health authorities. The writers modestly refer to the superficialities of their survey, but from a practical point of view it is exhaustive. It occupies 150 pages of the bulletin and deals with the place of nutrition in public health programmes, the relation of national economics to physiology, the evolution of diets and dietary habits among different races, our present knowledge of nutrition, dietary and nutritional standards, problems of production and distribution of food, and educational principles and methods in relation to nutrition. References to 129 original articles are given. Of special interest is the emphasis laid on the international problem exhibited by insufficient or defective feeding in some countries while others are suppressing production or actually destroying food; and the preoccupation of governments with economic issues regardless of their public health repercussion. Economic nationalism and public health internationalism are, in the writers' view, incompatible. Special attention is also devoted to the diets of rural communities.

THE FARMER'S DIET

A recent inquiry[3] in Wales by Mr. J. P. Howell, M.Sc., into the economics of farming and its effect on the dietary of farmers' families deserves notice. From this limited investigation it would appear, as might be expected, that such families have a definite advantage over the average of the community both in the quantity and quality of foods consumed, this being especially noticeable as regards milk, butter, and potatoes, although they may lack the variety which they would choose if the opportunity were afforded. These observations are obviously not applicable to the case of the farm labourer, whose family dietaries are apt to be lacking in first-class protein and whose children, walking considerable distances to school, often suffer from the lack of a proper midday meal.

CONSUMPTION OF MILK

Burnet and Aykroyd devote a good deal of attention to the special value of milk as an article of diet and the efforts which have been made to promote its consumption. Figures are frequently quoted as to the relative quantities consumed in different countries, but comparatively little is known about the use of milk in different social classes and the form in which it is purchased. Two recent inquiries made in Cardiff [4] and the distressed areas of South Wales [5] by the Department of Agricultural Economics of Aberystwyth University College are therefore of interest. In the former four samples each of about 100 families were investigated, grouped roughly as good middle class, good working class, new housing area and poor working class. Figures are given showing the decline of consumption of liquid milk from 0·55 pint per head per day to 0·16 with descent in the social scale, and the reverse process as regards tinned milk (mostly skim). Among the poorer families those with children purchased less milk on the average than those consisting entirely of adults, and many children received nothing but skimmed condensed milk. In the Rhondda valley there is less distinction of class and less variation in milk consumption. The daily consumption of liquid milk (including public supplies) over 602 families averages 0·236 pint per person, raised to 0·327 pint when forms of "milk-stuff" such as tinned and dried milk (but not cream) are included. As another recent investigation showed,[6] more liberal public assistance and supply of free milk in the Rhondda than in Cardiff seems to be associated with a better state of nutrition in the poor children of the former area.

SCHOOL MEALS

The administration of supplementary feeding of school-children continues to be a subject of controversy. The points at issue are connected with the practice of the Unemployment Assistance Board of making deductions from family allowances in certain instances in consideration of free meals granted to children by education authorities; and the medical selection of children for free meals which the Board of Education demands. As to the former no public health question seems to arise if the scales of assistance can be regarded in themselves as adequate to maintain the physical fitness of a family and the deductions are equitable. On the second point the essential criticism is that the detection of incipient malnutrition is beyond the skill of the medical practitioner within the time available for the purpose and that, in its logical application, every child who appears to have reached normality ought to be deleted from the list of grantees until he presents fresh evidence of deprivation. Operation on these lines of Section 84 of the Act of 1921 is not a procedure with which either education authorities or the medical profession desire to be associated. In fact it is rarely, if ever, interpreted in this way, but some medical officers find themselves troubled with qualms of conscience when invited to certify children whose family circumstances are poor but whose physique is apparently unimpaired. It would seem that medical selection of grantees for free milk, at least, should not be enforced, for the cost is not great and the mental, as well as the physical, benefits of extra milk rations have been so repeatedly and convincingly demonstrated among those otherwise normally fed that the case for raising the general standard of nutrition by its liberal administration is overwhelming. The British Medical Association has expressed its disagreement with the Board of Education's policy in this respect, and most school medical officers concur. The scheme could hardly be worked without an intolerable amount of friction and discontent—except in the spirit of make-believe which the Board tacitly encourages—unless the whole framework of the school medical service were radically reformed. Such a reform, involving continuous contact of the school medical department with each child throughout his school life, is perhaps desirable, but that is at the moment a reformer's dream.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 27TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1612; diphtheria, 983; enteric fever, 49; acute pneumonia (primary or influenzal), 386; puerperal fever, 36; puerperal pyrexia, 109; cerebro-spinal fever, 15; acute poliomyelitis, 18; acute polio-encephalitis, 3; dysentery, 13; ophthalmia neonatorum, 97. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 2nd was 2611, which included: Scarlet fever, 724; diphther[illegible] fev[illegible]; [illegible]ies [illegible] neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 9 (0) from measles, 2 (0) from scarlet fever, 20 (10) from whooping-cough, 23 (3) from diphtheria, 48 (8) from diarrhœa and enteritis under two years, and 19 (4) from influenza. The figures in parentheses are those for London itself.

Again no general increase is reported in the deaths from diarrhœa and enteritis, but Liverpool reported 14 and Birmingham 3. Fatal cases of whooping-cough increase as fatal cases of measles diminish: 15 of the 20 deaths occurred in Greater London, 2 in Manchester. Liverpool reported 5 deaths from measles, Sunderland 2. Of the fatal cases of diphtheria 3 occurred at Bradford, 2 each at Tottenham and Liverpool.

The number of stillbirths notified during the week was 275 (corresponding to a rate of 39 per 1000 total births), including 38 in London.

London Association of the Medical Women's Federation.—The July meeting of this association was held at the British Postgraduate Medical School, *Ducane-road*, Shepherd's Bush. After welcoming the members to this new school, Prof. F. R. Fraser noted the broad differences between the types of clinical cases seen at Hammersmith Hospital (London County Council) to which it is attached and the voluntary hospitals. He showed some typical cases of rheumatoid arthritis, demonstrating the difference in mobility of joints and in general well-being between cases which had come under observation and treatment at an early stage and those which had been neglected. He emphasised the importance of keeping the joints moving and the value of heat, however applied, in treatment He also showed cases of osteo-arthritis and contrasted cases of heart disease in which the primary failure was on the right and on the left sides. Finally he showed a child with blue sclerotics and fragile bones. After the meeting the members were shown round the pathological department of the school.

CORRESPONDENCE

THE TOXICITY OF AVERTIN

To the Editor of THE LANCET

SIR,—The report by Dr. Cole in your last issue of a case of tetanus treated with continuous avertin anæsthesia confirms the belief of many that the toxicity of this drug to the liver has been exaggerated. Prof. Anschütz, of Kiel, informed me in 1932, and again in November, 1934, that he does not believe that avertin is a liver poison even if this organ were diseased. He continues to have good results with avertin in jaundiced patients even when the bilirubin figure is four times the normal. After operation he gives a large intravenous infusion of 5 to 10 per cent. glucose solution. He stated also that Kirschner, of Tübingen, has given 250 g. avertin to a 9-year-old boy for the treatment of tetanus.

During a recent visit to the United States and Canada, where the use of avertin is increasing, I could not obtain any evidence of liver damage. Wesley Bourne, of Montreal, who has given avertin in well over 1000 cases, is now giving it in full doses to children, doses that is to say up to 0·15 g. per kg., to obtain complete anæsthesia.

I have administered avertin on nearly 1700 occasions; no fatality has occurred which could be even remotely ascribed to liver failure. Fifty-nine patients have been operated on under avertin for disease of the biliary tract; two were suffering from jaundice and toxæmia, one due to acute cholecystitis and the other due to peritonitis; they were given full doses of avertin and made uninterrupted recoveries. In the whole series jaundice has occurred on but two occasions. An alcoholic woman was given a full dose of avertin and gas-and-oxygen with a considerable quantity of ether; the operation for removal of the gall-bladder revealed a condition of early fatty cirrhosis of the liver. Slight jaundice developed and cleared up in three days. The other case was that of a child with a long history of acidosis, whose tonsils were removed under avertin, gas-and-oxygen, and ether. He made a good recovery, but whilst in the nursing-home developed symptoms of appendicitis. Three weeks after the first operation the appendix was removed, again under avertin, gas-and-oxygen, and ether. Jaundice of a mild degree started four days afterwards and quickly cleared up. I have given avertin twice to a child in 14 hours, normal recovery ensuing. It will be noticed that both patients in my series who developed jaundice had been given ether; neither of the patients who were jaundiced at the time of operation was given ether. I am upheld in my view that ether should be avoided in these cases by Prof. Anschütz who has completely given it up for patients with severe jaundice.

The oft-quoted experiments of F. B. Parsons have, I submit, received undue attention. Prof. E. D. Adrian who reported on this work states that "his results, though negative, are of considerable value as they show that avertin has not the toxicity to the liver which seemed probable from earlier work" (Brit. Med. Jour., 1932, ii., Suppt., 170).

I am, Sir, yours faithfully,

FRANCIS E. SHIPWAY.

York-terrace, N.W., August 6th.

PROCTALGIA FUGAX

To the Editor of THE LANCET

SIR,—In your last issue Dr. Hess Thaysen of Copenhagen has drawn attention to a peculiar visceral neurosis, which must, I think, be fairly common. A number of cases have come my way. Several have been in medical men. They tend to occur especially *at times of fatigue and stress.* I would particularly draw attention to the nocturnal incidence of the symptom, and agree with him that it is almost certainly a rectal rather than an anal phenomenon. One medical patient of mine tells me that she can obtain the quickest relief by inflation of the rectum with air, and for this purpose she keeps a rectal tube and bulb handy, both at her bedside and in her laboratory. Relief by this means suggests that the basis of the pain is probably spasm. Some of the painful colonic neuroses are similarly relieved by warm enemata.

I have notes of cases in which this tendency to acute but transient attacks of rectal pain occurred in association with colon spasm, or with other well-recognised allergic disorders. In none of my cases has there been any evidence of tabes dorsalis or of any local organic condition to explain the predisposition to these distressing crises. Not infrequently they engender a fear of organic disease, but the description of the attacks, their duration, and other associations, together with an ordinary examination usually allow a full reassurance.

I am, Sir, yours faithfully,

Wimpole-street, W., August 2nd. JOHN A. RYLE.

To the Editor of THE LANCET

SIR,—Dr. Thaysen's contribution on rectal pain is interesting, but raises one or two points which require comment. The histories of the cases cited resemble closely the stories told one by sufferers from rectal crises, so that unless a test was done in every case it would be difficult to exclude tabes as being an underlying cause. Another possible explanation of pains of such severity is dilatation of a hollow viscus. No amount of rectal dilatation will cause pain, so that it is possible that the rectal pain may be due to dilatation of a ureter, the nerve-supply, both spinal and autonomic, being similar. Extension of the pain peripherally could be accounted for by the distribution of the obturator nerve. Gravel has not the sonority of that hexameter ending proctâlgia fúgax, but I suggest that it may occasionally cause a true rectal crisis.

It is a pity that the patient who "thought he was able to detect some swollen veins in the rectum" was not further interrogated. It is impossible to feel swollen rectal veins digitally, so what ingenious arrangement enabled him to examine his own fundament?

I am, Sir, yours faithfully,

Harley-street, W., August 3rd. CHRISTOPHER HOWARD.

"NATUROPATHS"

To the Editor of THE LANCET

SIR,—In your issue of July 13th I gave an account of some recent activities of the medical herbalists. I would like to-day to refer to another cult, the "Naturopaths," who since 1934 have "established a register" which it is declared "is designed to protect the public and the fully trained naturopath from those who with inadequate knowledge claim to practise as "Nature-cure physicians."

I have before me a form of registration issued by this body on which the applicant is asked to specify types of treatment which he gives, and the following are cited as examples of such treatment: "psychoanalysis, colonic lavage, electrotherapy, biochemistry, herbal medicine, orificial surgery, &c." A circular issued with the application-form makes the following statement:—

> "Our standard of professional education is four years' full-time training with clinical experience. As the profession is still young, however, it has been impossible for many now in practice to obtain such a complete equipment. We are therefore following the example set by other young professions, and accepting proportionate experience in practice in lieu of a certain amount of training. Full information regarding both should be supplied on the printed form."

An applicant for registration may have to submit to an "examination" for which a fee of two guineas is payable on application. "Cheques to be made out to the treasurer of the Incorporated Society of Registered Naturopaths."

It seems to be common form with the irregular cults (probably in imitation of the most blatant of them, osteopathy) to name "four years' training" as the basis of "professional education," but no mention is made in the literature supplied to the applicant for registration in Naturopathy of any schools at which training can be given. The "British School of Osteopathy," "founded in 1917," posed, until its recent devastating exposure by the Select Committee of the House of Lords, as giving its "graduates" a "four years' course," the first two of which were declared to be "the same course as medical students take," and the dean of the school received the honour of publication of a half-column letter in large print in the *Times* of Nov. 6th, 1933. The recent Bill for Registration of Osteopaths gave the British School of Osteopathy the fullest recognition and proposed that it should be represented upon the board which was "to enforce a prescribed standard of education" and "keep a register similar to the register maintained by the General Medical Council," and yet the Lords' Select Committee found that the British School of Osteopathy "was exposed in the course of evidence before us as being of negligible importance, inefficient for its purpose, and, above all, in thoroughly dishonest hands."

The present rage for setting up "registers" of bodies of irregular practitioners and "schools" for their training is a phenomenon which I think deserves careful consideration by the medical profession. I have drawn the attention of the Minister of Health to the scandal presented by these schools which fraudulently pretend to qualify persons to practise various branches of medicine and surgery, and I have received to-day a letter containing his promise to look into the matter.

I am, Sir, yours faithfully,

House of Commons, August 2nd. E. GRAHAM-LITTLE.

HEADACHES

To the Editor of THE LANCET

SIR,—I am grateful for Dr. Geoghegan's kindly reference in your issue of July 20th to my Croonian lectures. As regards "neurasthenia" and "nervous exhaustion," there are two elements in any form of nervous breakdown, however slight: (1) the weakness or instability of the patient's nervous system, (2) the strain to which it has been subject. In some cases, after examination of the patient and consideration of his story, the physician forms the view that the first factor is the chief one. Among these were the neurasthenics. If the strain has been excessive and the patient is judged to have been less unstable before it than those in the first class, he is counted among the cases of nervous exhaustion. This is a clinical classification which I believe to be useful. It affects prognosis as well as diagnosis.

The word "worried" relates to external an sometimes lesser stresses in a person whose nervou system is thought to be of average stability. It i not really mine, and I do not like it. In the notes however, taken by various physicians and in th letters from the family doctors, it occurred so ofte —e.g., "worried about business," "worried abou children's health"—that I thought it better, in summary of clinical records, to put it in than t translate it.—I am, Sir, yours faithfully,

Ruthin Castle, N. Wales, July 31st. EDMUND SPRIGGS.

A LESSON IN ANATOMY

To the Editor of THE LANCET

SIR,—A neat though painful demonstration i practical anatomy which I had yesterday may interes some of your readers. While picking lavender i the garden, and sniffing it enthusiastically, I felt tingling in the left nostril. After sneezing convulsively for a few minutes, I finally blew hard an ejected an ant, which had evidently stung me Intense pain and a certain amount of swelling an lacrymation rapidly developed, and there was pai nearly as intense in the left upper alveolus and th left hard palate, illustrating most effectively th intimate connexion between the nasal branch o the mandibular nerve (second div. of the Vth) and the *anterior superior alveolar branch*. Some pain radiated into the left ear, but barely reached the eye.

What interested me was the feeling of familiarity about the pain in the alveolus, as I frequently have neuralgia there (where the teeth have long since gone); and a recurrent herpetic eruption and ulceration in the hard palate comes just where the pain was worst yesterday. I realised that I should have been treating the nose, where I did not suspect infection, for this troublesome condition. Swabbing inside the nose with hot sod. *bicarb.* solution gave a little relief, and after about an hour the pain and swelling died away.

The ant, I may say, was not dead, and I left it on the edge of my handkerchief to dry, whence it later took its departure.

I am, Sir, yours faithfully,

Princes Risborough, Bucks, August 2nd. J. WILTSHIRE.

A SALARIED SERVICE OF MIDWIVES

To the Editor of THE LANCET

SIR,—I have read in THE LANCET of August 3rd a letter from Miss Carter, organising secretary of the Midwives' Institute, and I would like to endorse all that she has to say. There can be no doubt that a salaried service of midwives will have to come and it is only right that those midwives who have been working for a number of years under unfavourable conditions should have an opportunity, as Miss Carter suggests, of being included in this service or should receive some compensation for giving up altogether.

After having watched the work of midwives for a number of years I most heartily agree with Miss Carter when she says that "it is generally recognised that midwives in this country . . . can show amazingly good results and an honourable record of the care of their patients." It is certainly high time that things were made more favourable for midwives, as the conditions under which they have been working in the past are truly deplorable and would not be tolerated by any organised trade-union for a moment. They are expected to work 24 hours a day, live in wretched quarters, and have nothing to look forward to in their old age. It is quite common for a medical man when he is called to a midwife's case to find that

that midwife has been on duty with that case 24 hours, and it is truly the duty of the medical profession to see that these things are altered. That they can be altered I have not the slightest doubt, and it appears to me that the easiest way to bring this about would be for medical men to refuse to work with any midwife who was not receiving proper remuneration and living under satisfactory conditions.

I do not think there can be any doubt that an important contributory factor to our maternal mortality is fatigue on the part of the attendant. The midwifery service of the future, I believe, will be one worked very largely by midwives who will work under proper conditions of service and will be allowed to administer to their patient some form of relief—chloroform or gas-and-air analgesia—during their labours. In this way both midwives and mothers will be greatly benefited.

I am, Sir, yours faithfully,

Station-road, New Barnet, August 2nd. JOHN ELAM.

THE EVOLUTION OF MEDICAL POLICY AND PRACTICE

To the Editor of THE LANCET

SIR,—Your leading article of August 3rd on contract practice foreshadows the development which is likely to occur. Will this be accompanied by an evolution in the present policy for the treatment of patients? There are several possibilities. Will the present system of individualism with a large measure of inevitable inefficiency be perpetuated?—That this is so now is shown by the crowded out-patient departments of the voluntary hospitals. Will there be a large extension of this system for suburban areas by municipal hospitals supported by the rates? Will there be an extension of the school medical service to deal in the first instance with adolescents and finally with adults?

Will a complete State medical service be formed to deal with all or nearly all the population? Or will doctors coöperate to provide at their own expense a first-rate medical service for the whole population, and will they make the health of all their aim in life, trusting to a wide extension of the insurance system to make this possible?

Medical work has become more exact and needs expensive apparatus and workers specially trained to use it. This is true not only for X rays and microscopy but also for investigating those areas in the body where special forms of illumination are needed. No single general practitioner or specialist is likely to be able to provide all the apparatus for the newer forms of physical treatment. A group of practitioners and specialists could do so? A "medical house" with a clerical staff, consulting-rooms, and nurses, a laboratory, X ray room, baths, and electrical treatment rooms would replace the usual consulting-rooms found in the houses of most doctors. The standard of practice where one of these existed would be raised in a whole district.

An imperfect analogy may make clear the main point in my mind. When a motor car needs attention would we prefer to take it to a small garage or to a modern service station? A motor car is simplicity itself compared to our bodies.

I am, Sir, yours faithfully,

August 5th. A. R. FRIEL.

BLEEDING OF TRANSFUSION DONORS

To the Editor of THE LANCET

SIR,—I have tried several devices for facilitating the removal of blood from the donor's vein, including the use of a pump. My present choice is not a complicated apparatus, but something very simple. I use an ordinary stainless Record needle, No. 15 B.W.G., with a sharp point and a short bevel, attached to about two feet of rather narrow rubber tubing, No. 10 Arnold. About six inches from the needle the length of tubing is broken by a glass connexion which acts as a window. At the operation the tubing hangs loosely and therefore almost vertically into a flask held just above floor level by an assistant. I have found that a pint of blood can almost invariably be collected in under ten minutes with the greatest ease. I think the secret lies in the long tubing which acts as a siphon.

In giving blood to the recipient, there is one problem which I believe has not yet been solved—how to insulate that tubing between the flask and the patient's arm to prevent the blood from cooling. Both a short tube and wrapping round the tube obstruct the ease of approach to the vein. I suspect cooling of the blood is one factor in subsequent reactions, and hence the problem is of importance.

I am, Sir, yours faithfully,

Nottingham, August 5th. P. H. O'DONOVAN.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Summer Adjournment

ON August 2nd both Houses of Parliament adjourned for the summer recess until Oct. 29th. Resolutions were passed to the effect that both Houses may meet at an earlier date at the discretion of the Lord Chancellor and the Speaker of the House of Commons. In the House of Lords the Royal Assent was given to 95 Acts, including the following: Appropriation Act, University of Durham Act, Diseases of Animals Act, Criminal Lunatics (Scotland) Act, Public Health (Water and Sewerage) (Scotland) Act, Housing Act, Housing (Scotland) Act, Government of India Act, National Health Insurance and Contributory Pensions Act, Restriction of Ribbon Development Act, Ministry of Health Provisional Order Confirmation (Leigh Joint Hospital District) Act, Ministry of Health Provisional Order Confirmation (Cuddington Joint Hospital District) Act, Ministry of Health Provisional Order Confirmation (Fylde, Preston and Garstang Joint Small-pox Hospital District) Act, Ministry of Health Provisional Order Confirmation (Ottershaw Joint Hospital District) Act, Hertfordshire County Council Act, and St. Bartholomew's Hospital Act.

On Wednesday, July 31st, the Voluntary Hospitals (Paying Patients) Bill was read a second time in the House of Commons.

University of Durham Commission

Under the University of Durham Act, 1935, which has now received the Royal Assent, the following Commissioners are entrusted with making Statutes for the University and its constituent Colleges: The Rev. F. H. Dudden, D.D. (chairman), Countess Grey, C.B.E., Sir W. Ross Barker, K.C.I.E., C.B., Mr. J. H. Priestley, D.S.O., Mr. C. Williams, O.B.E., M.A., Mr. G. R. Murray, M.D., D.C.L., F.R.C.P., Mr. T. F. Sibly, D.Sc. LL.D., Mr. A. Wood, D.Sc., with Mr. A. C. Dawes, B.A., LL.B., as secretary.

A New Attested Herds Scheme

In the House of Lords on Aug. 1st Earl DE LA WARR, Parliamentary Secretary to the Ministry of

Agriculture, admitted that the Attested Herds Scheme was not being taken up by the average farmer. They were, therefore putting forward proposals for altering the scheme. In addition to the bonus of one penny per gallon on milk from attested herds sold through the provisions of the Milk Marketing Scheme it was proposed to offer additional financial assistance to herd owners in suitable cases. Where an owner could produce veterinary certicates showing that he had reduced the number of reactors to the tuberculin test in his herd to not more than 10 per cent. the Ministry would be prepared to consider an application for a contribution towards further tests of the herd up to a maximum of four tests in order to assist the owner to complete the eradication of the disease and enable him to qualify for attestation. The contribution would be at the rate of £1 1*s.* plus 2*s.* 6*d.* for each animal tested in respect of each herd test.

Secondly, in place of the single official test at present required to determine the final qualification of a herd for a certificate of attestation, the Ministry would be prepared, in cases in which one or more reactors were found at such test, to repeat the official test at intervals of between 60 and 90 days for a maximum of three further herd tests before refusing the application. The cost of all official tests was defrayed by the Ministry.

Thirdly, herds undergoing a series of assisted or official tests under the foregoing provisions would be termed supervised herds and be subject to certain rules for the purpose of preventing the reintroduction of infection. To assist the owners of these supervised herds to obtain the right type of cattle to replace reactors the Minister would be prepared to make a contribution of from £3 to £5 towards the cost of replacing a reactor of the same class, except that no contribution would be paid towards the cost of an animal under 21 months' old unless the animal was a bull which had been licensed by the Ministry under the Improvement of Livestock (Licensing of Bulls) Act. The larger sum of £5 would be contributed towards the cost of obtaining an animal from an attested herd, £3 being the amount of the contribution in respect of an animal from any other herd. It was estimated that in the case of the average herd containing, say, twenty milking cows, the contribution towards the cost of testing would be £38, and on the assumption that a contribution would be made in respect of eight reactors on the average for each supervised herd the amount of such contribution towards the replacement of reactors would be £32, bringing the total additional financial assistance thus afforded to about £70. The operation of these provisions would be carefully watched, and in any event they might only be available during the period of four years specified in Section 9 of the Milk Act, 1934.

The intention of these proposals was to afford special assistance to the owners of suitable herds to complete the task of cleaning up their herds with a view to qualifying for attestation as tubercle-free herds, and it was hoped that they would produce a satisfactory response from herd owners.

Alcohol and Motor Driving

In the House of Commons on Aug. 2nd, on the motion for adjournment, Mr. ISAAC FOOT called attention to the report recently issued by the British Medical Association in answer to a request from the Minister of Transport (see THE LANCET, Aug. 3rd, p. 259) on the question of the effect of alcohol on motor drivers. The importance of the report lay in the attention it drew to the effect of the subintoxicant dose of alcohol, an amount less than that customarily regarded as rendering a person under the influence of drink or incapable of having proper control of a vehicle. The real danger upon the roads was not the drunken man but the man who was in charge of a dangerous machine and who had taken sufficient alcohol to give him a false confidence. There was, he thought, a definite obligation on the Ministry of Transport, and indeed on the House of Commons, to see that those facts were made known to all concerned. The fact that something like 80 to 90 per cent. of the municipalities of the country, and the great public utility companies, made abstinence a condition of service for men who were driving vehicles or acting as conductors was in itself conclusive evidence. He suggested that the report should be more widely published.

Captain AUSTIN HUDSON, Parliamentary Secretary to the Ministry of Transport, agreed that the more publicity the report obtained the better the effect would be. Between the time when the report was asked for and the time when it was received the Ministry, he said, inserted in the Highway Code a reference to the use of alcohol which said: "Before using the road be sure that your alertness or sense of caution is not affected by alcohol or fatigue." The Highway Code had a circulation of some 13,000,000 or 14,000,000, and was being widely read. He thought that Mr. Foot was wrong in thinking that the Ministry were not giving enough publicity to this question of alcohol. In the B.M.A. report the last sentence of all was, he thought, the most important. This ran:

> "After taking alcohol he may believe himself"—that was the driver—"to be driving better, but in fact, his body works less efficiently. This adverse effect generally occurs even if alcohol is taken in moderate quantities some hours before driving, and especially if taken in the absence of food."

He hoped that publicity would be given to that statement.

HOUSE OF COMMONS

WEDNESDAY, JULY 31ST

Nursing-homes and Traffic Noise

Mr. LENNOX-BOYD asked the Minister of Transport whether he was aware that there were one or more streets in London wholly occupied by nursing-homes and institutions; and whether, in the case of such streets, he would consider controlling heavy traffic, at any rate during the hours of the night and early morning.—Mr. HORE-BELISHA replied: If my hon. friend will furnish me with the names of the streets he has in mind I will have the matter examined.

Alcohol and Motor Driving

Sir FRANCIS FREMANTLE asked the Minister of Transport if he had considered the report of the committee of the British Medical Association on the influence of alcohol on motor driving; whether he would issue the report for the use of members of Parliament; and what action he proposed to take in the matter.—Mr. ISAAC FOOT asked a similar question.—Mr. HORE-BELISHA replied: The report to which my hon. friends refer was issued with the *British Medical Journal* for July 27th, and is therefore generally available. The report does not itself suggest to me any definite line of action, but I am sure that the public will be grateful to the British Medical Association for the time and trouble they have taken in carrying out this inquiry, and for the interesting material which it contains.

Dwelling-houses and Air Raid Protection

Mr. NEIL MACLEAN asked the Home Secretary the estimated cost of making the rooms in an average sized dwelling-house gas proof against air raids.—Sir J. SIMON replied: The cost of protecting rooms against gas would vary according to the size and construction of each room, the number of windows and doors and the state of repair. It is not contemplated that in an ordinary house more than one room should be made fully gas proof, but in addition a double gas-proof door, or air-lock, should be provided at the outer door of the house. I am advised that the cost of materials needed to construct this air-lock and to protect one room that was in reasonably good repair ought to be less than £1, exclusive of blankets and rugs which might be assumed to be available in the house. I am having special investigation made of the simplest methods of providing the necessary protection so that the cost of materials may be kept to a minimum and that the ordinary householder may, if he wishes, do the work himself.

THURSDAY, AUGUST 1ST

Miners' Nystagmus and Workmen's Compensation

Mr. GODFREY NICHOLSON asked the Home Secretary the terms of reference and the name of the chairman of the committee which he proposed to appoint to inquire into the operation of the Workmen's Compensation Act in relation to workmen affected by miners' nystagmus.—Sir J. SIMON replied: Briefly, the matters on which the committee will be invited to report are the operation of the Act in relation to miners' nystagmus; the position of the medical referees under the Act, and the arrangements generally for dealing with medical issues, and certain important questions arising in connexion with the settlement of claims by payment of lump sums. I am glad to state that His Honour Judge Stewart has consented to act as chairman of the committee.

Hospital Patients and Precautions against Air Raids

Mr. DOBBIE asked the Home Secretary whether, in the provision of gas masks for protection of the civil population during air raids, arrangements would be made for masks of a size and kind suitable to children; and if arrangements were being made to safeguard patients in hospitals and institutions where the inmates were unable to look after themselves.—Captain WALLACE, Under-Secretary, Home Office, replied: Yes, Sir; these matters will be considered.

Mr. MORGAN JONES asked the Home Secretary whether the gas-mask which was being advised by the Government for use by the civilian population would be able to resist the action of suffocating vesicant and corrosive gases; for how long the masks would offer protection in use; and whether materials were available for the making of such gas-masks in quantities for the whole civilian population, with quantities sufficient to allow for reserves and for deterioration and damage.—Captain WALLACE replied: The Government will only recommend the use of respirators which will afford protection against all known forms of gas which it would be practicable to use in war, for periods believed to be sufficient for the wearers to reach safety. Persons who might have to remain at work in gassed areas would need respirators giving a longer period of protection. It is not at present possible to quote precise figures of the duration of protection of different types of respirators. There is no reason to anticipate any difficulty in the supply of materials for the full number of respirators required.

Milk-supplies to Hospitals

Mr. LEONARD asked the Minister of Agriculture if he was aware that the vice-chairman of the Scottish Milk Marketing Board had stated that the Board were sympathetic to the request of hospitals and infirmaries for a special rate for milk-supplies, but were restrained by the fact that legislation bound them only to apply special rates to what could be termed a new demand; and if he would amend the Act so as to permit public institutions to have the advantage of special terms for milk.—Sir GODFREY COLLINS replied: The statement referred to has not come under my notice, but it is doubtless the case that the Scottish Milk Marketing Board are not in a position to give special terms to the hospitals and other such institutions in the absence of provision for Government assistance for such a purpose in the Milk Act, 1934. As stated in reply to previous questions, the matter raises large issues of policy, which will have to be considered in conjunction with the report of the Milk Reorganisation Commission.

Paratyphoid in Essex

Mr. THORNE asked the Minister of Health if he could give any information in regard to the outbreak of paratyphoid at Grays, Essex, and neighbouring towns; what action was being taken to prevent the disease from spreading; and what was the cause of the outbreak.—Sir KINGSLEY WOOD replied: I understand that 21 cases of paratyphoid were notified in the urban districts of Grays Thurrock, Purfleet, and Tilbury, and the rural district of Orsett, in the six weeks ending July 27th. The outbreak has been under investigation by the medical officer of health and a visit has been paid by a medical officer of my department. All cases were promptly isolated and the routine disinfection carried out. The cause of the outbreak has not yet been determined but investigations are still in progress.

OBITUARY

DAVID RICE, M.D. Brux., M.R.C.S. Eng., D.P.H.

WE regret to record the death of Dr. David Rice which occurred on Wednesday, July 31st, at Lower Hellesdon, where he had been lying ill for some three months. He was the son of the Reverend C. H. Rice, rector of Cheam, and was educated at St. Columba's College, Dublin, and Guy's Hospital. He took the English double qualification in 1898 and immediately started on his successful career as an alienist. He was for a time attached to the Bethlem Royal Hospital, and from 1899 to 1907 he was medical officer at Staffordshire County Asylum. He was later appointed medical superintendent of the Hellesdon Hospital, Norwich, a post which he held for 27 years, acting also as medical adviser to the Norfolk Committee for the Care of the Mentally Defective. He was particularly well read in his subject, was up to date in his views, and a capable administrator, so that he gained rightly a high reputation for his achievement at Hellesdon. Outside his professional work Dr. Rice was a great lover of music, while he had been a prominent cricketer. He leaves a widow, two sons, and a daughter.

EDWIN ALBERT CHILL, O.B.E., M.D. Edin.

THE death occurred suddenly on July 23rd of Dr. E. A. Chill, at his home at Battle where he was living in retirement. He was born in Burma in 1861 and educated at King's College School, London, proceeding for his medical training to the University of Edinburgh. He graduated in 1883 as M.B., C.M., proceeded to the M.D. degree, and held several appointments in London as clinical assistant, notably at Great Ormond-street Children's Hospital and the Central London Throat, Nose, and Ear Hospital. He was then for a period in practice in Ealing, a member of a very successful firm, and during the war as a captain R.A.M.C. was commandant of the Ealing V.A.D. auxiliary hospital at Southall. His connexion with the V.A.D. was important, for he was chief commandant of the Middlesex organisation and assistant county director of the British Red Cross and Order of St. John. At the conclusion of hostilities he received the O.B.E. He was a prominent freemason and published at various times lectures on anthropology and freemasonry.

ALFRED JOSEPH McCONNELL, M.B., Ch.B. Edin.

Dr. A. J. McConnell was born in Ballymena, Antrim, in 1886, the son of William McConnell, of Trostan, Ballymena. He was educated at Ballymena Academy and received his medical training at the University of Edinburgh. He graduated in 1909 as M.B., Ch.B., and following his qualification held the post of assistant resident medical officer at Smithdown-road Hospital, Liverpool, until 1912. He then settled down in general practice, but on the outbreak of war joined the R.A.M.C. with the rank of captain and served with the corps from 1916 until the conclusion of hostilities, spending the greater part of the time in Salonika. After the war he returned to Liverpool and resumed his practice, which he was carrying on at the time of his death, which occurred after a short illness at the age of 49.

J. C. R. writes: "The district of South Liverpool and those of his colleagues who knew him regret sincerely the recent death of Dr. A. J. McConnell. He was one of the most unassuming men in Liverpool, but both colleagues and patients alike were invariably impressed by his genial personality and unobtrusive kindliness. He was especially expert in midwifery, and many patients have good cause to thank him for his skill and judgment. He leaves a widow and a family of six children, two of whom are medical students."

ARTHUR ALAN MILLER, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng.

Arthur Alan Miller, who died on July 17th, had been in ill-health for some time though remaining courageously at work.

The second son of the late G. W. Miller, he was born in 1874 and educated at Forest School, Walthamstow, entering Guy's Hospital in 1893 where he had a successful medical career as a student. He was one of the most popular men who ever entered Guy's, for he was a clever amateur actor and also a good dramatic writer. He had a very large share in the Guy's Hospital paper, "The Guyoscope," the most successful of all hospital comic issues while it lasted. Thus he was invaluable at all hospital concerts and dramatic entertainments, and Mr. Eason, the superintendent of Guy's, writes that no one in the last generation has ever quite filled his place in the social life of the hospital. After qualification he was house physician at the General Infirmary, Northampton, and later took the degree of M.D. Durh. He now practised for a few years in Sutton, but moved to Westminster not long before the war, and while practising there and also in the City of London he published a book on the care of children, a subject where he was able to show the practical knowledge gathered from an appointment at the Evelina Hospital.

Early in the war he joined the R.A.M.C., and saw varied service in casualty clearing stations in France, Mudros, Egypt, and Italy, and was mentioned in dispatches. The end of the war found him acting lieut.-colonel in command of a casualty clearing station on the Italian front, and later he served for six years at the Ministry of Pensions. He then resumed his practice in the City where he was medical adviser to several important banks and companies.

In 1924 he married Eleanor, daughter of the late Rev. J. C. Street, and leaves a young son.

Throughout his life Dr. Miller remained interested in the stage. He wrote several sketches for Arthur Roberts and George Graves, and among his plays was "The Gipsy Princess," "A Night Out," "The Early Girl," and "Motherhood," while in conjunction with George Arthurs he wrote the Aldwych farce, "Marry the Girl."

MEDICAL NEWS

University of Oxford

On August 3rd the degree of B.M. was conferred on N. E. R. Archer, A. Fearnley, A. H. Hunt; T. W. H. Porter, and K. C. Royes.

University of Cambridge

The John Lucas Walker studentship for original research in pathology has been awarded to Mrs. M. E. Adair, Ph.D., who was recently a junior Beit memorial fellow. The Gwynaeth Pretty studentship for the encouragement of research in the ætiology, pathology, or treatment of disease, and the Nita King research scholarship for original research in the ætiology, pathology, and prevention of fevers have both been awarded to Dr. Reginald Passmore.

On August 3rd the following degrees were conferred :—

M.D.—G. J. V. Crosby.

M.B., B. Chir.—G. Blackburn, S. M. Evans, M. Hynes, H. B. D. Kettlewell, H. T. Laycock, C. W. A. Searle, T. M. Tyrrell, and J. N. Warren.

M.B.—W. S. Haynes, H. J. M. Robinson, and R. J. Still.

B. Chir.—A. W. Abramson, T. G. Armstrong, C. E. Bevan, W. G. Brander, G. R. Debenham, T. S. R. Fisher, A. R. Kelsall, W. A. Law, P. E. C. Manson-Bahr, J. H. Stothert, G. C. Tooth, and J. G. Webb.

University of London

Mr. Maxwell Ellis has been re-elected to the Duvene studentship in oto-rhino-laryngology for a further year. At the M.B. examination in May the university medal was awarded to Graham Hayward of St. Bartholomew's medical college.

At recent examinations the following candidates were successful :—

M.D.

Branch I. (Medicine).—F. R. Bettley, Univ. Coll. Hosp.; C. R. Birnie, King's Coll. Hosp.; K. C. Buck, St. Mary's Hosp.; Anthony Caplan, St. Bart.'s Hosp.; S. B. Dimson, Univ. Coll. Hosp.; A. E. Francis, St. Bart.'s Hosp.; D. H. Fulton, King's Coll. Hosp.; T. G. F. Hudson, St. Thos. Hosp.; I. G. Jones, Univ. Coll. Hosp.; Alexander Kahan, St. Thos. Hosp.; C. B. Lanyon, Univ. Coll. Hosp.; L. J. M. Laurent, Univ. Coll. and Univ. Coll. Hosp.; H. G. McComas, Guy's Hosp.; Ian More and R. S. Ogborn, Univ. Coll. Hosp.; Ruth Pumphrey, Univ. Coll. and Univ. Coll. Hosp.; R. S. Risk, St. Bart.'s Hosp.; K. M. Robertson, St. Thos. Hosp.; V. E. P. Senewiratne, Ceylon Med. Coll. and Univ. Coll. Hosp.; Rupert Shelley, St. Thos. Hosp.; Rupert Sykes, Victoria Univ. of Manch.; Joan B. Walker, Lond. (R.F.H.) School of Medicine for Women; Mary J. Wilmers, King's Coll. Hosp.; and J. L. Woodhouse, Guy's Hosp.

Branch II. (Pathology).—N. F. Maclagan, Middlesex Hosp.

Branch III. (Psychological Medicine).—J. G. Hamilton, Lond. Hosp.

Branch IV. (Midwifery and Diseases of Women).—Olive M. Midgley, London (R.F.H.) School of Medicine for Women; L. N. Reece and C. P. Scott, St. Thos. Hosp.

Branch V. (Hygiene).—V. F. Anderson, Westminster Hosp.; and Edith J. R. Browne, London (R.F.H.) School of Medicine for Women.

Branch VI. (Tropical Medicine).—K. V. Earle, Univ. of Camb. and St. Thos. Hosp.; and E. G. Wilkins, Middlesex Hosp. and London School of Hygiene and Tropical Medicine.

University of Bristol

The degree of M.D. has been awarded to A. C. Fisher for published work.

English Conjoint Board

At the recent final examination of the Board the following candidates were approved in the subjects indicated, but are not yet eligible for the diplomas of the colleges :—

Pathology.—O. B. Alakija, G. W. Alderman, J. D. F. Armstrong, Mary Barker, R. H. Barrett, E. A. Beet, R. H. Bembridge, C. Berens, Lily Black, E. Bolton, E. S. Bompas, G. L. Broderick, J. M. Brown, J. W. F. Brown, L. S. Calvert, P. C. Calvert, G. D. Channell, S. H. C. Clarke, J. C. Coates, W. A. Cobb, J. O. Collin, F. C. Collingwood, S. M. Cornes, B. K. Das Gupta, W. Davidson, D. L. Davies, L. E. C. Davies, W. H. Davies, L. J. D'Souza, J. Diver, H. G. Dowler, J. J. Dubash, P. S. Edgecombe, G. M. Fleming, H. R. W. Franklin, Joyce M. George, W. W. Gilford, E. Gillett, E. Gill-Carey, A. Gomez, A. C. F. Green, J. B. M. Green, L. Greenbaum, K. Hamiduddin, H. E. W. Hardenberg, A. J. Hardy, K. H. Harper, E. W. Hart, C. W. M. Harvey, F. E. S. Hatfield, W. H. Hayes, L. Heasman, R. K. R. Henry, A. G. W. Hill, J. E. Hill, G. T. Holroyd, T. H. Hughes, K. F. Hulbert, C. W. Hutt, G. A. Jackson, T. G. S. James, T. P. N. Jenkins, T. E. Johnson, H. Josephs, M. A. Kader, L. U. Kamm, E. Kaplan, R. G. M. Keeling, A. R. R. Kent, B. S. Kent, F. B. Kiernander, J. D. Kinnear, W. J. Latham, J. Lawson, A. R. Lee, I. Libman, A. B. Lintott, H. R. Loughran, A. A. Lovell, L. G. Lyle, L. McAskie, I. T. McGaw, D. H. Mackay, J. Mackellar, H. K. Meller, P. J. W. Mills, G. D. N. Milne, J. S. Minett, J. G. Mitchell, K. W. Monks, A. G. Moore, F. T. Moore, D. W. Moynagh, J. T. Murray-Aynsley, J. A. V. Nicoll, M. J. O'Donnell, M. G.

O'Flynn, N. O. Paterson, Nora M. Pettitt, W. J. E. Phillips, G. C. L. Pile, F. E. Pitt-Payne, Faith C. Poles, Helen S. Polson, Dorothy S. Pope, M. Price, P. J. Purcell, J. Razonsky, A. Reeves, J. L. D. Roberts, D. W. Rossiter, G. R. Royston, S. Sambandam, D. M. Samuel, H. V. Sankarayya, M. Schalat, G. E. B. Scott, J. S. H. Scott, Marjorie Smail. J. I. M. Smith, E. H. J. Smyth, J. B. Spearman, G. C. Steel, D. H. Swayne, R. D. Teare, R. F. Tredgold, R. C. Tudway, J. R. T. Turne, J. Vahrman, G. J. van der Merwe, G. O. Walker, S. Weinstcok, T. E. Whitby, A. M. Williams, H. T. H. Wilson, J. R. J. Winter, Ursula W. Wood, and C. A. Young.

Medicine.—M. A. Ahmad, I. C. Allen, S. Balasingam, E. J. W. Barnard, R. H. Barrett, P. N. Baruah, Agnes Y. Bowie, Josephine H. Campbell, S. S. L. Chiew, Priscilla B. Clark, J. D. Cooper, N. Cruickshank, G. G. Doel, J. J. Dubash, G. H. Ellis, Joan R. Franklin, D. W. F. Gotla, R. L. Hartley, R. A. Hoey, C. A. Hutt, M. Inayat-Ullah, J. I. A. Jamieson, H. G. Jones, D. B. Kulkarni, M. Lipson, H. S. Lohgarh, Ivy M. Massick, F. T. Moore, D. W. Moynagh, Moira Murray, J. A. V. Nicoll, Nora M. Pettitt, Dorothy S. Pope, R. R. Prewer, B. Robbins, W. A. H. Rushton, H. N. Savage, S. K. Sen, D. Singh, R. Srinivasan, J. S. Stuart, F. J. E. Stuhl, J. R. Sweeting, R. F. Tredgold, J. H. Ward, A. G. Waters, H. Weiner, Sheila M. R. Williams, S. L. Williams, and E. G. Williamson.

Surgery.—M. M. Ali, G. A. Armstrong, E. J. W. Barnard, H. F. Barnard, J. E. M. Barnes, F. G. A. Beckett, L. J. Blay, A. W. Bone, J. C. B. Bone, R. E. Bonham-Carter, C. M. Bowker, S. C. Buck, D. H. D. Burbridge, S. S. L. Chiew, T. K. Cooke, H. W. F. Croft, M. Curwen, B. J. Doran, C. H. Drake, T. P. Eddy, T. H. T. Gautby, T. D. Fraser, S. E. Furber, M. Gaba, D. R. Gibson, G. N. St. J. Hallett, R. L. Hartley, A. G. Hemsley, G. H. M. Hemsted, M. C. B. Heyns, B. B. Hickey, W. A. T. Hill, R. J. House, W. Hughes, C. W. Hutt, J. I. A. Jamieson, R. A. Johnson, W. E. Kershaw, F. B. Kiernander, M. Krone, J. W. Lacey, C. Langmaid, B. Lee, M. Lewis, R. G. M. Longridge, R. D. McDonald, K. G. F. Mackenzie, M. Mirsky, N. H. M. R. Monro, R. Mundy, R. O. G. Norman, K. J. O'Connor, T. D. W. Tredgold, R. C. Tudway, J. R. T. Turner, J. E. Underwood, W. M. Van Essen, J. R. Wardley, R. N. E. Watt, W. R. Welply, C. Weston, H. T. H. Wilson, Louise F Wilson, G. N. Wright, and P. J. M. Wright.

Scottish Conjoint Board

At recent examinations by the board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates were successful :—

F. C. Alexis, Paul Anyos, S. F. Aron, Komarraju Atchamamba, G. B. Beckner, W. M. Bennett, W. J. M. Beveridge, Aaron Caplan, A. S. Chiekrie, N. G. Clements, Michael Cohen, Hans Cohn, Albert Conn, Michael Dinner, A. H. Dobbin, A. H. Elder, I. J. Fernando, Harry Fischgold, J. A. Geerthsen, V. W. C. Gordon, J. E. Greene, H. R. Hagemann, Emmy Hahn, Meyer Hammer, D. T. Herkus, H. K. Hosny, H. N. Katz, T. S. B. Kelly, Ludwig Kleeberg, L. L. Kramer, Johan Kruger, Anna Lewin, Antony Lucas, Ilja Margolin, Ann W. M. Miller, Marjorie B. Morton, O. W. Nelki, C. B. Phillips, B. de F. Pieris, Egon Plesch, Abraham Rabinowitz, P. S. Reisman, L. A. St. L. Richards, Peter Salsberg, N. A. Samuels, M. J. A. Sandrasagra, Abraham Shechtman, H. B. Silverman, Herbert Simon, Simon Smulowitz, O. J. Sokoloff, L. N. Soon, Jack Squire, Hedwig Stern, Kurt Stern, W. P. Steyn, Samuel Stromberg, T. H. Thompson, A. S. Torrance, Ernst Widrich, G. E. W. Winter, and Ilja Wolpert.

Walsall General Hospital

Representatives of workpeople have visited this hospital to see how the money they collect is expended. The two new wards were made possible through the help of the workpeople's contributory fund.

King's College Hospital

Mr. Cecil P. G. Wakeley has been appointed by the council of King's College to be their representative upon the committee of management of King's College Hospital, in the place of Prof. E. Barclay-Smith, M.D., who served in that capacity for twelve years.

King's College Hospital Centenary

In 1939 King's College Hospital will celebrate its hundredth anniversary. It is over twenty years since the hospital moved from its original home in Portugal-street to Denmark Hill, the site of 12 acres being presented by the late Lord Hambleden.

Research Fellowships in Tuberculosis

The Medical Research Council have awarded Dorothy Temple Cross fellowships for the academic year 1935–36 for research in tuberculosis to Mr. G. B. Brook, D.Sc., senior assistant veterinary officer, Derbyshire county council ; Dr. J. W. Craig, assistant medical officer, King Edward VII. Sanatorium, Midhurst ; and Dr. A. H. B. Rhodes, house physician, Brompton Hospital.

Paddington Medical Society

A meeting of this society will be held on Tuesday, August 13th, at 9 P.M., at the Great Western Royal Hotel, Paddington, W., when there will be a clinical discussion by members on case problems in general practice.

National Hospital, Queen-square

A course of lecture-demonstrations on neurology will be held at this hospital from Oct. 7th to Dec. 6th. It will include demonstrations of anatomy, physiology, and pathology, and demonstrations on post-mortem material at noon ; lectures on the principles of neurology and on diseases of the nervous system at 3.30 P.M. ; and demonstrations of clinical methods of examination at 5 P.M. A second course will be held from Jan. 27th to March 27th. Further particulars may be had from the secretary of the hospital, Queen-square, London, W.C.1.

Invalid Children's Aid Association

This association will hold a joint conference with the Central Council for the Care of Cripples on the welfare of cripples and invalid children on Nov. 7th and 8th at the Drapers' Hall, Throgmorton-street, London, E.C. The conference will be opened by Sir Kingsley Wood, the Minister of Health, and the first session will be devoted to a discussion of infectious diseases, their after-effects, immunisation, and other preventive measures. The speakers will include Sir John Broadbent, Dr. Matthew Burn, Surgeon-Captain Sheldon Dudley, Dr. J. Alison Glover, and Dr. W. J. Pearson. At other meetings the after-effects of accidents will be discussed, and the speakers will include Dr. H. C. Cameron, Dr. Elizabeth Casson, Mr. S. A. S. Malkin, Dr. H. E. Moore, and Mr. Donald Norris. Further information may be had from the secretaries of the associations, 117, Piccadilly, W.1.

Presentations to Medical Men

On his retirement from the post of principal medical officer of the Welsh Board of Health, Dr. D. Llewellyn Williams received a presentation from the Welsh branch of the Society of Medical Officers of Health, meeting in Cardiff last month under the presidency of Dr. Thomas Evans, of Swansea. Dr. D. Rocyn-Jones, in speaking of Dr. Williams's great services to the public health service, recalled the time when there were only three county medical officers in Wales—Dr. Williams, Dr. W. Williams, of Glamorgan, and himself. Other speakers included Prof. R. M. F. Picken, Dr. Colston Williams, Dr. Dan Powell and Dr. T. B. Smith.—In the city council chamber at Leicester, on July 26th, Dr. C. Killick Millard received presentations and an illuminated address in recognition of his work as medical officer of health. References were made to his unselfishness and generosity and to the magnificent success that has attended his efforts to lower mortality and increase health. In the course of his reply Dr. Millard remarked that if he were dictator the first thing he would do would be to bring in compulsory superannuation.—After 21 years at Ravensthorpe, in Yorkshire, Dr. James A. Stewart is retiring to live at Brighton, and last month a meeting was held to express the respect and affection of the townspeople among whom he has been working. Part of the presentation was made on behalf of the local ambulance brigade, in which Dr. Stewart has successfully trained 200–300 candidates for examination.

NOTES, COMMENTS, AND ABSTRACTS

THE SIGNIFICANCE OF PERSISTENT HIGH BLOOD PRESSURE [*]

By L. N. Jackson, M.C., D.M.

I PROPOSE in this paper to deal with persistent arterial hypertension from the point of view of prognosis, and I have chosen this subject and this particular aspect of it for several reasons. I have chosen it first, because, I think, prognosis is a branch of medicine about which the general practitioner ought to know more than his consultant colleagues, since he has better opportunities of following up cases until they finally perish under his care. Secondly, I have chosen it because I believe that as prognosticians we doctors have a definite civic function to perform, quite apart from any other uses we may have to the community. If we cannot cure a patient we ought at least to be able to forecast with some degree of accuracy what measure of health he is likely to enjoy, and when he may expect to die, so that he may put his affairs in order. My third reason is that I happen to have been interested in essential hypertension for a number of years. It has been a sort of hobby of mine. Just as one man may collect stamps or old china, so may another collect hyperpietics. Finally, I have chosen it because, it seems to me, that many of my own and previous generations in the profession are hazy about the significance of persistent hypertension.

Persistent arterial hypertension nowadays is usually classified as follows :—

1. *Renal hypertension*, the type found in association with certain cases of that variety of Bright's disease usually known as chronic glomerulonephritis.

2. *Non-renal hypertension*, sometimes called essential or benign hypertension, a disease of unknown ætiology which was first differentiated from Bright's disease by Allbutt, and called by him hyperpiesia.

3. *Malignant hypertension*, about which I shall have something to say later.

Let us begin by considering the first group, renal hypertension. What happens to renal hypertensives ? How long do they live ? Statistics are dull things, so I will refer to them as briefly as possible. In 31 cases of renal hypertension which came to autopsy at the London Hospital, the average age at death was *forty-five*. Renal hypertensives do not make old bones. Why not ? What kills them ? The cause of death in 84 cases which came to autopsy was as follows :—

1. Uræmia (facile princeps) accounted for 49 cases (about 60 %).
2. Cerebral hæmorrhage ,, ,, 18 ,, (,, 20 %).
3. Cardiac failure ,, ,, 7 ,, (,, 8 %).
4. Other causes ,, ,, 10 ,, (,, 12 %).

Thus the common fate of the renal hypertensive is to die in the fifth decade of life. The kidney lesion is the nigger in the woodpile. In two cases out of *three*, the kidney lesion comes to dominate the clinical picture, and the patient dies of renal failure.

Now we come to the second group, the non-renal or essential hypertensives. How long do they live ? In 86 cases of essential hypertension which came to autopsy at the London Hospital, the average age at death was found to be *sixty*, and many of these cases were complicated by *other* life-shortening diseases such as rheumatic endocarditis. What do essential hypertensives die of ? The cause of death in 123 autopsy cases was found to be :—

1. Cardiac failure .. .. 56 cases, that is 45 % (nearly half).
2. Cerebral hæmorrhage .. 33 ,, ,, ,, 27 %
3. Other causes .. .. 34 ,, ,, ,, 28 %

Uræmia, nil.

So much for hospital records. What about cases observed in general practice ? In 20 cases of essential hypertension dying under our care, the average age at death was nearly *seventy*. I have 26 patients who have been under observation for periods varying from fourteen years to two months and whose average age is nearly *sixty-nine*. This series includes a young man of twenty-five in whom the diagnosis is doubtful ; without him, the average age would be *seventy-two*.

Thus, the fate of the non-renal hypertensive is very different from that of the renal. The subject of uncomplicated essential hypertension may reasonably expect to live into the seventh or even the eighth decade. The kidneys, though they share in the arterio-sclerotic process, are not seriously functionally impaired. Death occurs from cardiac failure or cerebral hæmorrhage, and *not from uræmia*.

We therefore have to deal with two morbid conditions which when first seen may be clinically almost identical but in which the prognosis is very different. Obviously the differential diagnosis is worth making. How is it to be done ? Sometimes it is so easy that a policeman, or perhaps a surgeon, can make it. In other cases it is so difficult as to defy even a general *practitioner*. It must be admitted at once that, in doubtful cases, repeated observation at infrequent intervals may be necessary before the diagnosis can be established with anything like certainty. Remember, the blood-chemistry will not help, for by the time that a high blood-urea indicates renal insufficiency the diagnosis of renal hypertension can be made by looking at the patient's face. To wait for a rising blood-urea before making the diagnosis is like waiting for fæcal vomiting before diagnosing acute intestinal obstruction.

Renal or Not ?

When confronted by a hypertensive patient, what are the points that will help us to decide whether he is suffering from renal or non-renal hypertension ? No single one of them is infallible though some are more suggestive than others. Neither condition is rare, though there is no doubt that essential hypertension is far commoner than renal hypertension.

First, the *history*. If there has been an illness in the immediate or remote past suggesting acute glomerulo-nephritis, or other acute infection, such as scarlet fever, which is liable to kidney complications, suspect renal rather than non-renal hypertension. Secondly, the *age-incidence*. Renal hypertension is a disease of young middle-age, say thirty to forty-five. Essential hypertension, so far as we know, is not usually present before the fifth decade. Therefore, in a young subject, say under thirty, be very chary of diagnosing essential hypertension even when no abnormality is found other than a persistently raised blood pressure. Thirdly, the *appearance* of the patient may help. The renal hypertensive is apt to be pale, thin, and lethargic ; the essential hypertensive is apt to be ruddy, often fat, and energetic. Fourthly, as to the *height of the blood pressure*. In renal hypertension, blood pressures, both systolic and diastolic, tend to run higher than in non-renal hypertension. Moreover, in renal hypertension, blood pressures tend to rise as time goes on, whereas the non-renal may be stationary or nearly so for many years. There are, however, plenty of exceptions to this rule.

Cardiac hypertrophy is common to both conditions and is of no importance in differential diagnosis. The same applies to arterio-sclerosis. Arterio-sclerotic changes in the retinal vessels occur in both conditions, and I have never met an ophthalmic surgeon who would commit himself to a differential diagnosis on the retinal picture alone, though there seems to be evidence that multiple flame-shaped hæmorrhages and exudate speak in favour of renal hypertension, and are of sinister prognostic significance. I have no doubt that hæmorrhages do sometimes occur from the arterio-sclerotic retinal vessels of non-renal hypertensives, but often they are solitary and clear up.

---

[*] A paper read before the Exeter Medico-Chirurgical Society on April 25th, 1935.

Fifthly, the *urine*. Fixation of the specific gravity at a low level, say 1010, is an important point in favour of renal hypertension. Twenty-four hourly specimens are hard to come by in general practice. The patients are apt to send up all the urine passed in twenty-four hours, which sometimes entails their hiring a cart to convey it to the surgery. A good substitute method is that described by Fishberg.

"About 6 o'clock of the evening before the test, the patient has his usual supper, which should not contain more than at most 200 c.c. of fluid, but in which it is advantageous to have a considerable amount of protein food. After this he neither eats nor drinks anything until the test is over. Before retiring, he empties his bladder; this urine is discarded as is any urine passed by the patient during the night. On wakening in the morning he passes urine which is kept in a separate bottle. He remains in bed and again empties his bladder one hour after awakening. He is then up and about (if able to do so) for an hour and at the end of this time voids into a third bottle. Each of the three bottles should be labelled with the time when the urine was passed. Thus, if the patient awakens at 8 o'clock the three specimens will be passed at 8, 9 and 10 o'clock. The patient has had sixteen hours in which to "concentrate" with little inconvenience. In private practice with morning surgery hours, it is also a convenience that the patient can bring the three specimens to the surgery soon after 10 o'clock. The specific gravity of each of the three specimens is then taken. If kidney function is unimpaired, the specific gravity of at least one of the specimens will exceed 1022, often going as high as 1032. Older individuals often do not concentrate as well as the young. In very severe impairment of renal function the maximum specific gravity is only 1010, and in intermediary cases figures between these extremes are obtained. In patients with true uræmia the maximum is under 1020 and usually much closer to 1010." From "Hypertension and Nephritis" by A. M. Fishberg. London, 1930, p. 51.

Polyuria is, I think, of no great significance. Both renal and non-renal hypertensives may be polyuric at least until renal or cardiac failure develops in the former, or cardiac failure develops in the latter. Albuminuria is fairly constant in renal hypertension and albumin is often present in large amount; it is inconstant and scanty in essential hypertension in the absence of chronic myocardial failure.

The presence of casts is not of much help. Granular casts tend to be more abundant in renal than in non-renal hypertension. Red blood-cells and leucocytes on the other hand, if present in any number, speak for renal hypertension, assuming, of course, that the urinary tract is otherwise healthy, and free from such conditions as pyelitis or renal calculus. To exclude leucorrhœal contamination catheter specimens are advisable in women.

Two Typical Cases

Perhaps I may shortly quote a typical example of each. First a case of renal hypertension.

A tall, puffy, pasty boy of seventeen, had measles followed by broncho-pneumonia in infancy. At the age of nine he had a short febrile illness. A cloud of albumin was found in the urine which was clear within a week. At the age of twelve he was sent home from school with a temperature of 102° F. and an enlarged tender right post-auricular gland. His eyelids were puffy and the urine showed a heavy cloud of albumin, which persisted as a faint haze. At the age of fourteen he had a cold followed by persistent pyrexia, up to about 100° and highest at midday. He had large tonsils, puffy eyelids, and a cloud of albumin. The blood pressure was 150/100. The fundi were normal. The specific gravity of the urine was 1010. Later a trace of blood appeared in the urine. Albuminuria and pyrexia persisted. His tonsils were removed without improving his general condition. Meanwhile his cardiac apex had moved out to the left.

He was investigated in hospital. Blood cultures and agglutination reactions were negative for the typhoid group and *Brucella abortus*. His blood-urea in April, 1932, was 53 mg. per 100 c.cm. and during his stay in hospital he showed renal inadequacy in the urea-concentration test. In November, 1933, the urine had a specific gravity of 1018, contained a heavy cloud of albumin, and microscopically showed leucocytes, red cells, hyaline, granular and leucocytic casts. The blood count showed a slight secondary anæmia. Since then he has persistently shown mild pyrexia. The urine examined on twelve occasions has always contained albumin, varying from a heavy cloud to a 1/12 volume. The specific gravity of twenty-four hourly specimens of urine has varied between 1020 and 1010. The blood pressure is rising steadily, and recently has always been in the region of 165/75.

I think that there is no reasonable doubt that this boy is suffering from chronic glomerulonephritis of the hypertensive type, and that he is doomed to die young, and most probably of uræmia.

Now compare and contrast that case with the following:—

Five years ago an old lady of seventy-four, complained of a blind spot in her right eye which developed quite suddenly and was like a tea-cosy in shape. She was seen by Mr. P. D. Warburton who observed a retinal hæmorrhage in the macular region. Mr. Ransom Pickard saw her about a month later. His report was as follows: "At the right macula there was a circular patch, deep red in colour, with a border of grey pigment. At the edge of this below was a small hæmorrhage. The right fundus showed slight cutting of the retinal veins by their arteries, but was otherwise normal." Except for this blind spot she felt quite well, though she confessed to slight dyspnœa on exertion. There was no œdema, no headache or vertigo, and in fact no other symptom. The urine had a specific gravity of 1011, and there was a haze of albumin. The blood pressure was 220/140. Two years ago she had an attack of abdominal discomfort and flatulence, and also attacks of tightness in the chest at night which made breathing difficult, and lasted for perhaps an hour or two. Her apex-beat was observed to be just outside the nipple line. These symptoms rapidly subsided with rest, and when seen about a month ago at the age of seventy-nine, she said she felt very well. There was no headache, vertigo, or tinnitus. Her hearing was fair. There was slight dyspnœa and palpitation on exertion, but she could hurry upstairs. Her eyesight was now good. The blind spot had cleared up gradually, taking about a year to do so. There was no œdema. Her blood pressure was 200/140. The radial artery was just palpable, and the apex-beat just outside the nipple. She looked extremely well. The urine was normal, the specific gravity being 1020, and microscopically showed nothing except a few oxalate crystals, epithelial cells, and amorphous urates.

Here is a patient with essential hypertension who feels very well at the age of seventy-nine, and who, when she does die, if indeed she ever does, will die of progressive heart failure or cerebral hæmorrhage, *but not of uræmia*.

Does Malignant Hypertension Exist?

Now what is this thing called malignant hypertension? Some competent clinicians, notably Fishberg and Volhard, in America, whilst agreeing that 90 per cent. of essential hypertensives never show impaired renal function, maintain that the remaining 10 per cent. show evidence of renal destruction and die of uræmia. They say that, in these cases of essential hypertension, which behave normally for years or even decades, a malignant phase arises leading to rapid death. They claim to find at autopsy on these cases a necrosis and endarteritis of the renal arterioles which is followed by acutely progressive renal insufficiency. Other clinicians and pathologists disagree. Dr. Dorothy Russell, who can speak with authority on the pathology of Bright's disease, says that these cases of so-called malignant hypertension are merely cases of exceedingly chronic glomerulo-nephritis. She maintains that these vascular lesions in the kidney are part and parcel of Bright's disease, wrought by the same toxin which produces the glomerular changes. She adds that these same vascular lesions may occur in the early stages of Bright's disease before there is any question of hypertension.

Another argument against the existence of malignant hypertension is the difference in age-incidence. Malignant hypertension so-called occurs between the ages of thirty and forty. Essential hypertension arises between forty and sixty. This surely argues against malignant hypertension being a complication of essential hypertension.

Personally I am on the side of the pathologists. I think these cases in which malignant hypertension is said to supervene on essential hypertension are really mistakes in diagnosis, and that the case was really one of chronic glomerulo-nephritis—i.e., renal hypertension—all along. In my humble opinion, if one sees uræmia developing in a case which one has diagnosed as essential hypertension, the best way out is to admit to oneself (if to nobody else) that the original diagnosis was wrong, and not talk about malignant phases in the hope of laughing it off.

Morbid Adventures

It is probably true to say that, once established, essential hypertension seems to be permanent in the majority of cases, though there is evidence to show that hypertension arising during pregnancy and at the menopause sometimes disappears spontaneously.

Another interesting point is the extraordinary stability of the blood-pressure readings, both systolic and diastolic, in the majority of cases, except when the heart is failing. In some of my cases which have been under observation for years, the variations in individual blood pressures are extremely slight. A man whose blood pressure was 190/125 fourteen years ago, had a blood pressure of 185/110 when last seen a few weeks ago. A woman whose blood pressure was 210/115 nine years ago, when examined recently had a blood pressure of 200/115. The height of the blood pressure seems to bear no relation to the severity of the symptoms. A man with a blood pressure of 270/150 suffered no discomfort except for occasional slight headaches, and was able to do heavy manual work for years. Another man with a blood pressure never higher than 185/105 is permanently miserable with tinnitus, vertigo, and headache.

Essential hypertension is often said to be a disease of civilisation. The hardworking, hard-driving, hard-drinking business man is especially prone to it. I can only say that it is extremely common among the peasantry of Devon, some of whom have never hurried in their lives.

Apart from death in the seventh or eighth decade, various other morbid adventures are apt to befall the subject of essential hypertension. *External hæmorrhages* for example are very common, especially epistaxis which has occurred in 11 of my 46 cases, and hæmoptysis which has occurred in 3. Hæmatemesis and melæna from hypertension no doubt occur, but I have not encountered them, though I daresay that hæmorrhage from a gastric ulcer in one case was aggravated by coexisting hypertension. As a rule these patients seem to be rather refreshed by hæmorrhages, as by venesection; though, of course, the effect of hæmorrhage on the permanent level of the blood pressure is negligible. External hæmorrhages are not always, however, to be looked on with complaisance. In one of my cases a severe hæmoptysis immediately preceded death and, in another, severe epistaxis very nearly resulted in death from the hæmorrhage.

Diabetes mellitus is a well-recognised complication of essential hypertension. I have seen it in five cases, three of which have died. The prognosis, however, does not appear to be seriously affected by this complication unless insulin is given, in which case the patient does badly, since arterio-sclerotic vessels cannot stand it. A woman, aged fifty-three, with a blood pressure of 250/150 and chronic myocardial failure developed glycosuria. She was given insulin 10 units twice daily, and died suddenly four months later.

Cerebral hæmorrhages have been the sole or a contributary cause of death in at least 9 of my cases. Non-fatal strokes, probably due to small hæmorrhages, and ranging from complete hemiplegia to slight monoparesis, have occurred in 7 patients—four of these are still alive. One of them, a woman aged fifty-three, had a hemiplegia sixteen years ago, and is now able to get about with no more disability than a slight limp. Her B.P. is 200/115. Another woman, aged eighty-three, suddenly developed a paresis of her right upper limb nine years ago. She is now quite well, except for a slight clumsiness of her right hand. Her B.P. is 200/120. I have seen herpes zoster twice. This may be mere chance or due to small hæmorrhages in spinal vessels which have become sclerosed as a result of prolonged high pressure. Persistent hypertension though an undoubted cause of arterio-sclerosis is by no means the only, nor indeed, the most potent one. The *pipe-stem radial artery* appears to occur rather in what Allbutt called decrescent arterio-sclerosis—i.e., lean old men who have low blood pressures, small pulse pressures, and small atrophic hearts.

Gout has occurred only once in my series. There is no reason to believe that gout and hypertension have anything more in common than a tendency to occur in the same type of person.

Chronic *cholecystitis* and hypertension seem to have more in common. Cholecystitis occurred in 5 of my patients, all of whom have died. Three of these were not considered fit for operation. One died very shortly after operation, and one several years after a successful cholecystectomy. This was the patient already referred to who died suddenly after hæmoptysis. It should be mentioned in passing, that simple hypertension per se is no contra-indication to giving a general anæsthetic.

Mild *general infections* are stood as well by essential hypertensives as by anyone else, but severe infections try them more than they do normal persons. An old woman of seventy-three went fairly well through a lobar pneumonia despite a B.P. of 190/115. Shortly afterwards, however, she developed signs of progressive heart failure. A man, aged forty-nine, with a B.P. of about 260/150 lived almost symptomless and was able to do hard manual work for eight years, but died in twenty-four hours from broncho-pneumonia.

There is no doubt that *cardiac failure*, or cardiac defeat as Allbutt called it, is the commonest cause of death in essential hypertension. Chronic myocardial failure is, or has been, present in at least 15 of my cases. Other cardiac disease accounts for another 7. Angina has occurred in 4, coronary embolus probably in 2, and Stokes-Adams disease in 1.

In conclusion, then, my advice to intending centenarians is, on the whole, to avoid hypertension if you can. If you cannot, choose the non-renal rather than the renal, and you need not despair.

THE HEAD OF OLIVER CROMWELL[1]

Canon Horace Wilkinson is in possession of a head impaled upon a rusted iron spike fixed on a decayed oak pole. This head is reputed to be that of Cromwell, and for a century past has been the subject of keen controversy, but until recent years no single trustworthy measurement of it had been undertaken, nor had any attempt been made to fit it to any of the known portraits of Cromwell. Canon Wilkinson, with much public spirit, gave permission to Prof. Karl Pearson and Mr. G. M. Morant, D.Sc. (1) to retain the head long enough to carry out a comparison with the available busts, masks, and portraits of

---

[1] The Portraiture of Oliver Cromwell, with special reference to the Wilkinson Head, by Karl Pearson, F.R.S., and G. M. Morant, D.Sc. Issued by the Biometrika Office, University College, London, and printed at the University Press, Cambridge. 1935. Pp. 116. 36*s*.

Cromwell; and (2) to state freely the conclusions reached as the result of their investigations.

The anatomical studies undertaken have been enriched by a wealth of historical and antiquarian information collected on the subject. Cromwell died at 3 P.M. on Sept. 3rd, 1658, aged 59. There appear to have been an autopsy and an embalmment. The authors suggest that the autopsy may have taken place soon after death from a suspicion of poison, and the embalming on the following day. As the brain was examined and apparently weighed, there can be little doubt that the skull cap was sawn off. At the autopsy the vessels of the brain are said to have been "overcharged," and the weight is said to have been 6¼ lb.—a figure which the authors reject as an exaggeration, the authority for the statement being far from clear.

An attempt was made, apparently with success, to give him the greatest funeral that had been seen in England; its cost was estimated as not more than £80,000. The effigy was adorned with crown, orb, and sceptre. This was probably one of the chief reasons for the subsequent (political) proceedings.

On May 25th, 1660, Charles II. landed in England, and ten days before that the House of Commons ordered that "John Bradshaw deceased, late Sergeant at Law, be one of those that shall by Act of Parliament be attainted of high treason for murthering of the late King's Majesty." The same order was made concerning Oliver Cromwell, Henry Ireton, and Thomas Pride deceased, and on Dec. 6th the House ordered that the bodies be taken out of their graves and drawn on a hurdle to Tyburn where they were to be hanged and then buried under the gallows. On Dec. 8th the Lords amended the order in the sense that the bodies should be hanged up in their coffins before burial. This "post-mortem" execution was carried out on Jan. 30th, 1661, the anniversary of the execution of Charles I. The sergeant-at-arms appears to have disregarded the order of the Lords and to have permitted the executioner to remove the bodies from their coffins for the hanging. Cromwell's body was encased in six layers of green cerecloth which made the task of the executioner who had to remove the head very difficult; according to an eye-witness he had to make eight cuts before he got the head off. The bodies were tumbled together into a pit already prepared beneath the scaffold; the heads were removed and placed over the south end of Westminster Hall, where Pepys saw them on Feb. 5th.

Applying this and other information to the Wilkinson head Karl Pearson and Morant show that it possesses a number of peculiar characteristics that go far towards establishing it as the genuine head of Cromwell. In the first place the head shows the circular saw cut made at the autopsy in order to remove the brain. Secondly, the head had been embalmed before decapitation, and had been cut off in the crudest possible manner: the first blows with the axe missed the vertebral column and later blows several centimetres further down left four vertebræ attached to the skull. The colour of the hair on the skull agrees with that of Cromwell's hair. The place where his celebrated wart was can still be seen and, lastly, careful anatomical measurements of the skull are compatible with those of the death mask and portraits of Cromwell. The authors found that a skiagram of the Wilkinson head showed the presence of a number of whitish spots chiefly on the frontals and parietals and sought the opinion of Sir Arthur Keith without informing him of the possible identity of the head. Sir Arthur expressed the view that they were Pacchionian depressions and added that: "It should be the skull of an oldish person and the bone formation is not normal. The condition is one of those classed as osteophoresis. I have seen the condition in the skulls of the insane." The authors add that in their opinion Cromwell was certainly not insane, but did suffer from a religious monomania.

The beautiful reproductions of the various portraits and miniatures of Cromwell greatly enhance the value of this book. Now that the identity of the skull is practically certain, might it not be reinterred—e.g., beneath Cromwell's statue outside Westminster Hall?

SOCIAL HYGIENE

THE value of the work done by the British Social Hygiene Council has lately been brought before our readers both by an appeal (March 23rd, pp. 688 and 702) and by reports of the proceedings of the seventh Imperial congress, held last month in London. The need for sympathy and support is again made clear by the annual report.

The year saw the first appearance of the Empire Social Hygiene Year Book (reviewed in our columns in September), which includes, besides particulars of the health services and vital statistics of the Empire, a careful survey of the problems of marriage, child welfare, delinquency, venereal diseases, tuberculosis, mental disorder and allied problems throughout the world, and also offers a number of essays on such subjects as biological studies in the universities and training colleges of the Empire, juvenile delinquency in the Dominions and Colonies, international aspects of the film, the social work of the League of Nations, and a study in comparative legislation. A second volume of this useful work of reference has now been published.

The report itself particularly emphasises the need of determined efforts to prevent inherited disease, and stresses the importance of the labours of almoners and trained social workers, who are, unfortunately, as yet available in less than a quarter of the treatment centres. Among the many subjects which have engaged the activities of the Council during the year are the welfare of members of the mercantile marine, sex delinquency in girls and general delinquency in boys, and the increase in tuberculosis and venereal disease in Bechuanaland. The sub-committee which has prepared a memorandum on marriage recommends special preparation for those about to be married, including instruction in the physiology and psychology of the married state. Voluntary submission to medical examination before marriage is also advocated. Since the only way of reaching those intending marriage is through ministers of religion and registrars, the coöperation of those people is essential, and the council proposes to call a conference and put the problem before them. The council is also using its influence to promote the appointment of trained married men and women probation officers to handle separation cases and conciliation proceedings in connexion with the courts. The medical advisory board is considering the whole question of securing the help of medical psychologists for magistrates.

NEW PREPARATIONS

OSTOCALCIUM TABLETS.—The conditions that are now recognised to call for the exhibition of calcium are receiving wide attention, directed especially towards the provision of salts of calcium in a readily assimilable form. The tablets, manufactured by Glaxo Laboratories, (56, Osnaburgh-street, London, N.W.), each contain grs. 7½ of calcium sodium lactate in combination with 500 international units of Ostelin vitamin D (Calciferol G.L.). The advantages claimed for the double calcium salt are that it is more palatable than other salts of calcium, and that the addition of calciferol renders assimilation more simple. The tablets are recommended for use in all conditions to which calcium prophylaxis is applicable as in allergic disorders, or to compensate for undue calcium drain. The Glaxo Laboratories have also added to their preparations CALCIUM LEVULINATE, which in the forms of 10 and 15 per cent. sterile aqueous solution of the calcium salt of levulinic acid, has been found useful for administration by injection.

ERGOMETRINE. (Allen and Hanburys Ltd., London, E.2, and British Drug Houses Ltd., London, N.1).—The isolation of ergometrine, an alkaloid of ergot, was described in the *British Medical Journal* of March 16th last, by Mr. H. W. Dudley, F.R.S., and Dr. J. Chassar Moir. Other references to the remarkable drug have appeared in medical literature, indicating that ergometrine may establish a claim to be an active principle of great practical importance, appearing indeed to have the action for which ergot was originally introduced into obstetrical and gynæcological practice. Ergometrine prepared in the laboratories of Messrs. Allen and Hanburys has been found to exhibit the characteristic effects of the crude drug, it is indicated therefore in all cases where ordinary ergot is indicated but might have the disadvantage of nauseating the patient. Messrs. Allen and Hanburys supply a sterilised solution in double ended ampoules, to meet employment by injection or by mouth.

The British Drug Houses have placed on the market ergometrine in tablet form for oral administration and samples are available for practitioners.

Appointments

DAVISON, GEORGE, M.D. Durh., has been appointed Medical Registrar at the Royal Victoria Infirmary, Newcastle-upon-Tyne.

KELLETT, C. E., M.D. Camb., M.R.C.P. Lond., Medical Registrar at the Royal Victoria Infirmary, Newcastle-upon-Tyne.

OSBORNE, R. P., M.B. Manch., F.R.C.S. Eng., Resident Surgical Officer at Park Hospital, Davyhulme, Manchester.

PHILIP, J. F., M.B. Aberd., Senior Resident Officer at Aberdeen Royal Infirmary.

Certifying Surgeon under the Factory and Workshop Acts: Dr. H. G. YOUNG (Hatfield, Hertford); Dr. R. A. F. CREET (Ripley, Surrey); and Dr. D. L. FREW (Greenlaw, Berwick).

London County Council Hospital Staff.—The following appointments, promotions and A.M.O. (I.) and (II.) and assistant . and II.:

CRAWFORD, D. K., F.R.C.S. Edin., St. Mary, Islington (has since resigned);

BEATTIE, D. A., F.R.C.S. Eng., A.M.O. (I.), Fulham;

MACKENZIE, E. F., M.B. Sydney, A.M.O. (II.), St. James'.

SINGER, J. P., B.A. Camb., M.R.C.S. Eng., A.M.O. (II.), St. George-in-the-East.

ROBINSON, M. H. B., M.B. Melb., F.R.C.S. Eng., Senior A.M.O. (II.), St. Charles';

GISSANE, W. C., M.B. Sydney, F.R.C.S. Eng., Senior A.M.O. (II.), St. James';

DEVIN, C. H., M.R.C.S. Eng., A.M.O. (I.), St. Luke's, Chelsea;

SMITH, D. W. G., M.B. Edin., A.M.O. (I.), St. Giles';

WILKIE, D., M.D., F.R.C.S. Edin., Senior A.M.O. (II.), St. Pancras.

Vacancies

For further information refer to the advertisement columns

Aberdeen University.—Lecturer in Morbid Anatomy in Dept. of Pathology. £400.

Aylesbury, Royal Buckinghamshire Hospital.—Second Res. M.O. At rate of £150.

Barnsley County Borough.—M.O.H., &c. £900.

Bath, Royal United Hospital.—H.S. and H.P. Each at rate of £150.

Birmingham, Ear and Throat Hospital.—Third H. S. At rate of £150.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Res. M.O. £300.

Birmingham United Hospital.—First Asst. for Neurological Dept. £200.

Birmingham and Midland Eye Hospital.—H.S. At rate of £130.

Bolton Royal Infirmary.—Res. Surg. O., also Asst. Res. Surg. O. £250 and £200 respectively.

Bradford, Grassington Sanatorium.—Asst. Res. M.O. £175.

Bradford Royal Eye and Ear Hospital.—H.S. £160.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £120.

Brighton, Sussex Eye Hospital.—Hon. Clin. Asst.

Cardiff, King Edward VII. Welsh National Memorial Association.—Half-time Asst. Tuber. O.'s. Each £250.

Cardiff, *South Wales, &c.*—Asst. Lecturer in 400.

Chelms —H.P. At rate of £150.

City of London Hospital for Diseases of the Heart, &c., Victoria Park, E.—H.P. At rate of £100.

Croydon Mental Hospital, Upper Warlingham, Surrey.—Sen. Asst. M.O. £600.

Dewsbury and District General Infirmary.—Sen. H.S. £200.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts. £175.

Durham County and Sunderland Eye Infirmary.—H.S. £350.

Fareham, Hants, Knowle Mental Hospital.—Jun. Asst. M.O. £350.

Glasgow, Lightburn Joint Hospital, Shettleston.—Res. Physician. £350.

Greenwich Metropolitan Borough.—Jun. Asst. Maternity and Child Welfare M.O. £500.

Hove General Hospital, Sussex.—Res. M.O. At rate of £150.

Huddersfield, Storthes Hall Mental Hospital, Kirkburton.—Fifth Asst. M.O. £350.

Hull Royal Infirmary.—Third H.S. At rate of £150.

At rate of £125.

At rate of £130.

Deputy Med. Supt. £700.

Liverpool, Alder Hey Hospital.—Res. Asst. M.O. £200.

Liverpool Heart Hospital.—H.P. At rate of £100.

London Homœopathic Hospital, Great Ormond-street, W.C.—Gynæcological H.S. At rate of £100.

Macclesfield General Infirmary.—Second H.S. £150.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Sen. Res. M.O. At rate of £125.

Manchester Ear Hospital, Grosvenor-square, All Saints.—H.S. At rate of £150.

Middlesbrough, North Riding Infirmary.—Third H.S. £125.

Middlesex Education Committee.—Teacher in Anatomy 2 gns.

reenwich-road, S.E.—2 Cas. O.'s. Each and H.S. Each at rate of £100.

Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. or H.S. At rate of £100.

Northampton General Hospital.—H.S. At rate of £150.

Northumberland C.C.—Asst. County M.O.H. £500.

Norwich, Norfolk and Norwich Hospital.—Cas. O. £120.

Nottingham General Hospital.—H.S. to Ear, Nose, and Throat Dept. Also Casualty Officer. Each at rate of £150.

Plymouth, City General Hospital.—Asst. M.O. Also Jun. Asst. M.O. £300 and £250 respectively.

Plymouth, Prince of Wales's Hospital.—H.P. At rate of £120.

Portsmouth Royal Hospital.—H.P. At rate of £130.

Post Office (Western District).—Medical Officer. £500.

Preston and County of Lancaster Royal Infirmary.—H.S. £150.

Hospital for Children, St. Quintin- .—H.S. At rate of £100.

Battle Hospital.—Res. Asst. M.O. £300.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Rotherham Hospital.—Cas. H.S. £150.

Royal Chest Hospital, City-road, E.C.—Med. Reg. £50.

Pall Mall East, S.W.—Milroy Lect.

.C.—Dental H.S. At rate of £80.

—Asst. M.O.H. £500.

es of the Genito-Urinary Organs, &c.

Second Asst. Cas. O. At rate of £80.

Shrewsbury, Royal Salop Infirmary.—Two Res. H.S.'s. Each at rate of £160.

Southampton Free Eye Hospital.—Locum Tenens Ophth. H.S. £6 6s. weekly.

South-Eastern Hospital for Children, Sydenham, S.E.—Two Res. M.O.'s. Each at rate of £100. Also Hon. Pathologist. £50.

Taunton and Somerset Hospital.—H.P. and H.S. Each at rate of £100.

Torquay, Torbay Hospital.—Hon. Surgeon.

University of Lc Pathology. £300. Also \ £200.

Ventnor, Isle of W *Consumption, &c.*—Jun. Asst. Res. M.O.

Warwick, King Edward VII. Memorial Sanatorium, Hertford Hill.—Jun. Asst. M.O. At rate of £200.

Wimbledon Hospital, Thurstan-road, S.W.—Res. M.O. At rate of £150.

Wolverhampton, Prestwood Sanatorium.—Asst. Res. M.O £400.

Wolverhampton, Royal Hospital.—H.S. for Fracture and Orthopædic Dept. At rate of £100.

Woolwich and District War Memorial Hospital Shooter's hill, S.E.—Res. M.O. £175.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Troon (Ayrshire), Rothes (Morayshire), Caerleon (Monmouthshire), and Milborne Port (Somerset).

Births, Marriages, and Deaths

BIRTHS

BROWN.—*On July 27th, at Selkirk, the wife of John Scott Brown, M.B. Edin., Uganda Medical Service, of a son.*

LAW.—*On July 30th, at Devonshire-place, the wife of Frank W. Law, F.R.C.S. Eng., of a daughter.*

SMITH.—*On July 28th, at Eton-villas, N.W., the wife of K. Shirley Smith, F.R.C.P. Lond., of a son.*

TINCKER.—*On July 30th, at Painswick, the wife of Surg. Lt.-Comdr. R. W. Holden Tincker, M.R.C.S. Eng., R.N.V.R., of a daughter.*

MARRIAGES

WINTER—RICHARDSON.—*On July 31st, at Newcastle, Lewis Bland Winter, M.D. Camb., Ipswich, to Ella, only daughter of Mr. J. G. Richardson, of Newcastle-on-Tyne.*

DEATHS

BIGGS.—*On July 28th, M. G. Biggs, M.D. Durh., of Rottingdean Heights, aged 86.*

FARIE.—*On August 5th, at Wimbledon Hill, S.W.19, Gilbert John Farie, M.C., M.B. Edin., in his 54th year.*

MCCALDIN.—*On August 3rd, at Wymeswold, Cecil McCaldin, F.R.C.S. Edin., of Nottingham.*

NASH.—*On August 2nd, suddenly, at Bedford, Walter Gifford Nash, F.R.C.S. Eng., aged 72.*

NEVILLE.—*On July 3* after a long illness, Thomas Neville,

RICE.—*On July 31st,* Norwich, David Rice, M.D. Brux., M.R.C.S. Eng., aged 64.

ADDRESSES AND ORIGINAL ARTICLES

THE MORBID ANATOMY OF CARIES OF THE THORACIC SPINE IN RELATION TO TREATMENT*

BY H. J. SEDDON, M.B. Lond., F.R.C.S. Eng.

RESIDENT SURGEON, COUNTRY BRANCH OF ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, STANMORE, MIDDLESEX

A CONSIDERATION of the treatment of spinal caries must still be based on a clear understanding of the morbid anatomy of the disease. As yet, no specific remedy has been discovered for the treatment of tuberculosis and the proven value of rest and open-air treatment in the cure of joint lesions has not abolished the need for rational mechanical treatment, founded on anatomical and physiological principles.

The morbid anatomy of caries of the thoracic spine is so wide a subject that I propose to refer only to certain aspects of the disease that have received little or no attention in the past. Spastic paraplegia, the most important complication of thoracic caries, has been dealt with recently by Butler and myself[1] and I shall not make more than a passing reference to this condition.

Anatomical Types of Spinal Caries

1. True *tuberculous arthritis* as found in the diarthrodial joints of the extremities, though occasionally seen in the spine, is relatively unimportant. It occurs most commonly in the occipito-atlanto-axial group of joints, and as a secondary condition in the posterior articulations of the cervical, thoracic, and lumbar vertebræ. So far as is known it never occurs as a primary lesion in these small joints.

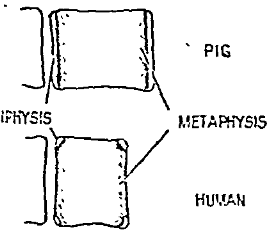

FIG. 1.—Diagram showing vertebral epiphyses of man and pig.

2. *So-called tuberculous epiphysitis* of a vertebral body is a well-known condition, and extremely common in the thoracic and lumbar regions. Strictly speaking, it is not an epiphysitis but rather a metaphysitis. In the typical vertebra of most young mammals the vertebral body is exactly like a long bone. There is a short shaft and two epiphyses. A few years ago the madder feeding experiments of John Hunter were repeated by Prof. J. C. Brash, who has been particularly interested in working out the growth of the mandible.[2] He has allowed me to examine the spines from several of his pigs that were fed on madder from an early age until a few weeks before death. The bones show clearly that all the longitudinal growth in the vertebral body takes place at the metaphyseal regions of the shaft exactly as in a long bone and that the epiphysis contributes little or nothing to the increase in length. In the human vertebra the epiphysis is reduced to an insignificant ring appearing at about the 12th year, and fusing at about the 24th. It contributes nothing to the growth in length, and it never appears to be the primary focus for tuberculosis of the spine (Fig. 1). The lesion is found on the upper or lower surface of the body and is therefore metaphyseal; for this reason the term epiphyseal tuberculosis should be discarded.

An interesting growth phenomenon connected with the metaphyses must also be mentioned. It is sometimes seen in the later stages of spinal caries in children. It has long been known that a prolonged increase of the blood-supply in the neighbourhood of an epiphysis may lead to increased activity of the growth centre. Excessive growth at the lower end of the femur in chronic osteomyelitis of the shaft and in protracted tuberculosis of the knee is familiar to all of us (Fig. 2). A few years ago J. G. Johnstone[3] pointed out that an overgrowth phenomenon may sometimes be observed in spinal caries, though he gave no explanation of the condition. In the cases he reported the rate of bone production in the surviving growth centres of diseased vertebræ was about twice as great as that in the normal vertebræ above and below the lesion. This must be due to long-continued hyperæmia of the growth discs immediately adjoining the lesion (Fig. 3).

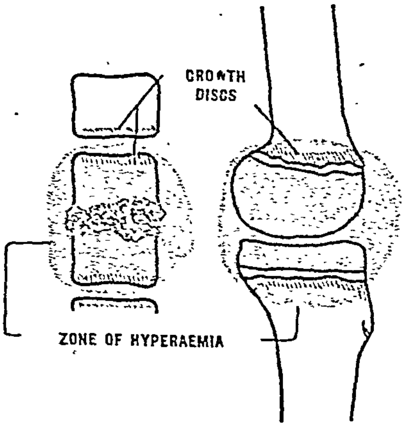

FIG. 2.—Diagram showing how a zone of hyperæmia due to chronic infection may influence adjacent growth-discs.

The earliest X ray sign of metaphyseal tuberculosis is narrowing of the joint space, due to simultaneous involvement of two adjoining metaphyses, and collapse of the intervening disc from interference with its nutrition.

Leriche[4] has stated that the narrowing of the joint space is due to compression of the disc brought about by spasm of the muscles around the lesion. This is hard to believe. The turgidity of the normal disc is so great that it cannot be compressed even by violent flexion of the spine; the vertebral body is crushed before the disc will yield. How could any muscles, however powerful, keep up the terrific force necessary to compress a disc for weeks on end? There is ample anatomical evidence to show that the disc is actually destroyed though not directly by the disease (Fig. 4).

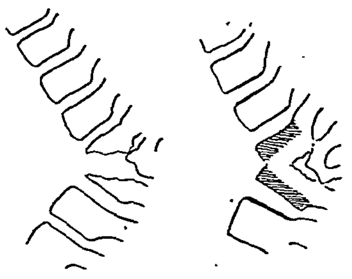

FIG. 3.—Tracings from strictly comparable radiograms of a child's spine showing (on the right) the new bone (shaded) laid down during the course of two years. There has been remarkable activity at the two growth, discs adjoining the tuberculous focus.

At this stage, no destruction of bone may be demonstrable radiographically, nevertheless the primary focus is not in the disc but in the bone.

3. A *diffuse osteomyelitis* is also common. In the early stages it is sometimes apparent in the radiogram

---

* Hunterian lecture delivered before the Royal College of Surgeons of England, 1935.

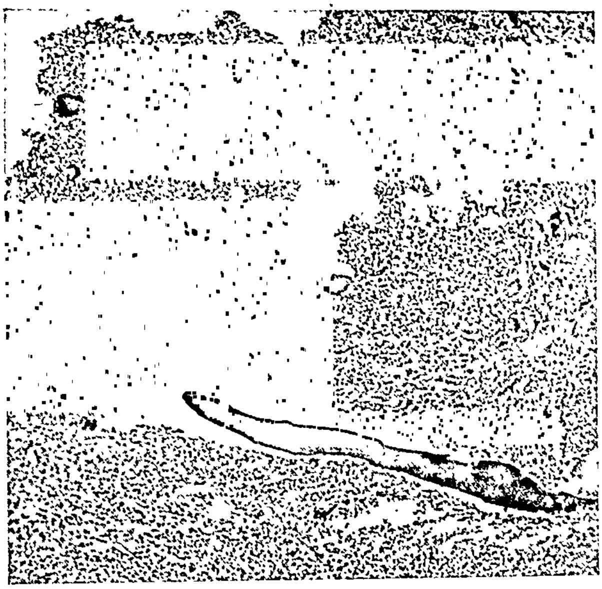

FIG. 4.—Microphotograph of a very early metaphyseal lesion. Tuberculous granulation tissue with giant cells on both sides of an intervertebral disc which is melting away, but shows no signs of actual disease.

as an increase in density of the vertebral body, which is of value in diagnosis. In two cases where secondary foci were suspected in a known tuberculous spine, a diffuse increase in density of two or three vertebral bodies enabled one to localise the new focus. A similar appearance is sometimes found in metaphyseal lesions. It may represent a miliary necrosis of bone with deposition of lime salts. In some cases massive necrosis follows with wholesale destruction of bone; in other cases a more slowly developing rarefaction appears in the usual way. The danger is to mistake this increased density for a sign of healing.

The osteomyelitic focus may lead to widespread destruction of bone within a single body, which may collapse like a concertina, slowly or suddenly. If the collapse is sudden, some of the inflammatory products may be squirted backwards into the vertebral canal and inflict irreparable damage on the cord.[1]

A less malignant infection leads to cavitation of the vertebral body and sometimes the formation of sequestra.

4. Very occasionally the primary focus may appear on the anterior or, less commonly, the posterior surface of a vertebral body—a *so-called periosteal lesion.* It cannot be diagnosed until erosion of the bodies has occurred or until the cord has been compressed—if the disease has commenced under the posterior common ligament.

The spread of a thoracic abscess upwards or downwards causing elevation of the anterior common ligament and erosion of the anterior surfaces of the vertebral bodies adjoining the primary focus is thought by some to be a secondary periosteal lesion (Fig. 5 A). Ghormley and Bradley [5] have pointed out that a collection of pus, tightly compressed between the anterior surfaces of vertebral bodies and the anterior common ligament, may well transmit the pulsations of the aorta to the bone in much the same way as the sac of an aneurysm, and that the erosion so frequently found in tuberculosis is therefore probably of mechanical origin. Four points may be advanced in favour of this suggestion:—

(*a*) The intervertebral discs are often spared, though not to the same degree as in true aneurysm.

(*b*) The aneurysm-like erosion is never found above the arch of the aorta, although anterior abscesses are not infrequent above this level.

(*c*) When an abscess spreads longitudinally under the posterior common ligament such bony involvement as does occur is never of the type found anteriorly—that is, uniform cupped excavation of each vertebral body.

(*d*) In two recent specimens that I have been able to examine there was no tuberculous disease of the eroded vertebræ.

The condition is easily recognised radiographically and it is well to look for it seeing that true involvement of a body may develop anywhere along the course of the abscess. In a number of specimens I have found that the infection has broken in at a higher level—a true secondary focus has formed (Fig. 5 B).

Having defined the four general types of spinal caries; the diarthrodial joint infection, the epiphyseal or rather metaphyseal lesion, infection of the cancellous bone (osteomyelitis), and lastly periostitis, we may now consider the chief forms of the disease as it affects the thoracic spine.

The Typical Lesion

The typical thoracic lesion commences either as an osteomyelitis or a metaphysitis of one or more vertebræ. The tendency to extensive spread of the disease is far greater than in the cervical or lumbar regions, and the reason for this is to be found in the peculiarities of the thoracic spine. In the first place, the thoracic spine is subject to constant respiratory movement much of which takes place between the diseased vertebræ, a point that can easily be verified during the performance of a costo-transversectomy. Many years ago Ménard [6] pointed out that bone destruction in tuberculosis is the result either of *tuberculous ulceration* or *mechanical ulceration,* or both. Tuberculous ulceration is due solely to the activity of

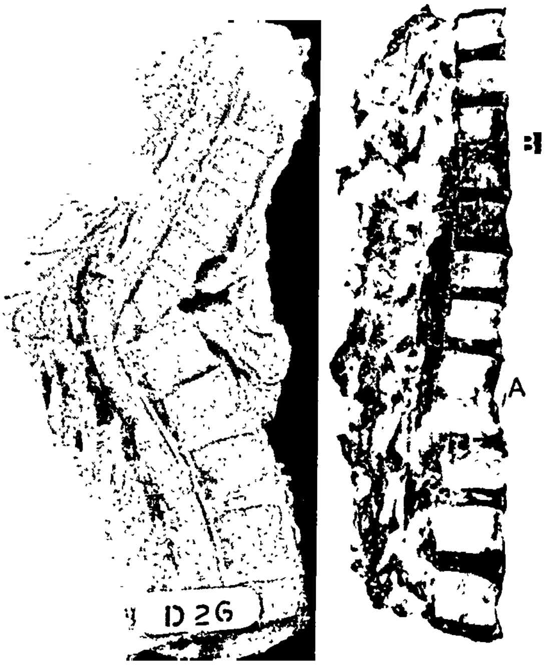

FIG. 5.—On the left is an excellent example of aneurysm-like erosion of several vertebral bodies. (Middlesex Hospital Museum.) I am indebted to Prof. James McIntosh for permission to reproduce this photograph. In the photograph on the right A is the primary focus. A large fusiform abscess has gradually spread upwards and led to anterior erosion of seven vertebræ and the development of a secondary focus at B. The progress of the condition was followed radiographically.

the disease: mechanical ulceration is the result of movement—friction between inflamed and softened joint surfaces. The thoracic movement in a case of caries leads to mechanical ulceration equalled in severity only by that found in neglected hip disease. The natural thoracic kyphosis also encourages this process. Another factor tending to produce widespread destruction is the close confinement of a thoracic abscess by the strong anterior common ligament and its lateral expansions. In the cervical or lumbar regions, abscesses track away from the spine with the greatest ease. This is rare in the thoracic region, and the extension of a fusiform thoracic abscess may lead to aneurysm-like erosion of many vertebræ and the development of secondary foci above or below the original lesion (Fig. 6 A and B). Where the erosion is purely of the aneurysm type no great damage is done, but the appearance of secondary foci is a serious matter.

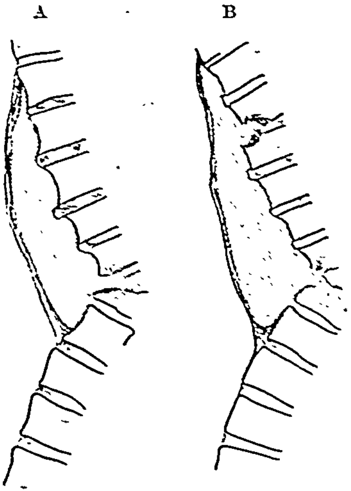

FIG. 6.—The drawing on the left is traced from a radiogram showing an aneurysm-like erosion of four vertebræ above a typical thoracic focus. That on the right shows a similar erosion with a secondary lesion at the upper limit of the abscess cavity. It made its appearance 2¼ years after the primary focus was detected.

With further local spread of the disease certain other conditions may arise, concertina collapse and sequestrum formation (to which reference has already been made), and lastly pathological dislocation of the spine. The importance of these three conditions is that they may give rise to severe and often fatal paraplegia.[1]

The evil effects of widespread bone destruction in the thoracic spine are sufficiently grave during the active stage of the disease, but if the patient escapes all these evils his troubles may not be over. Even when the lesion is quiescent or apparently healed further complications may develop.

The Late Complications of Extensive Thoracic Disease

When a number of vertebræ have been destroyed angulation of the spine invariably occurs; the process often begins during the active stage of the disease and may continue for years after the lesion has healed, while the patient is leading a more or less normal life. No form of external support will arrest this bending, and a bone-graft, at least in children, is equally ineffective.

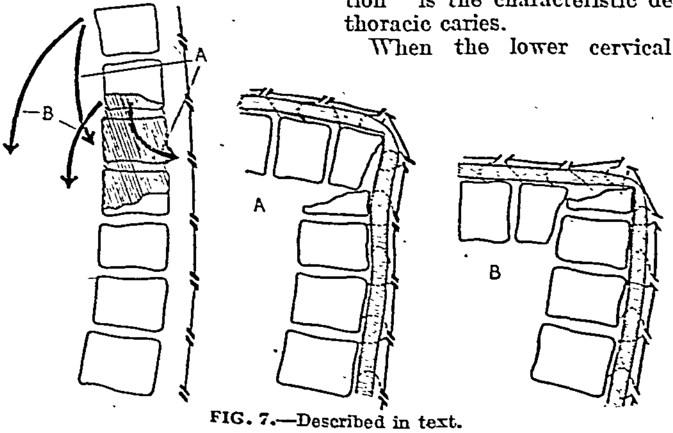

FIG. 7.—Described in text.

If the lesion is not extensive such small gaps as exist during the active stage of the disease are closed ultimately by the apposition of the surfaces of the involved vertebræ. When, however, a number of vertebral bodies have been completely destroyed, the segment of the spine above the lesion swings down through a quadrantal path in such a way that the lower surface of the vertebra above the gap cannot possibly come into contact with the upper surface of the vertebra below. The spinous processes, laminæ, pedicles, and articular processes of the vertebræ that have lost their bodies are responsible for this mechanism. For the sake of simplicity the loss of bone has been represented in the diagrams as confined to three vertebræ (Fig. 7). In actual fact the average number of bodies lost before any of these changes takes place is six. The segment of the spine above the lesion may travel in one of two directions: it may swing posteriorly over the upper surface of the vertebra below the gap (A), or slide down along the anterior face of the lower segment of the spine (B). Let us consider the latter first.

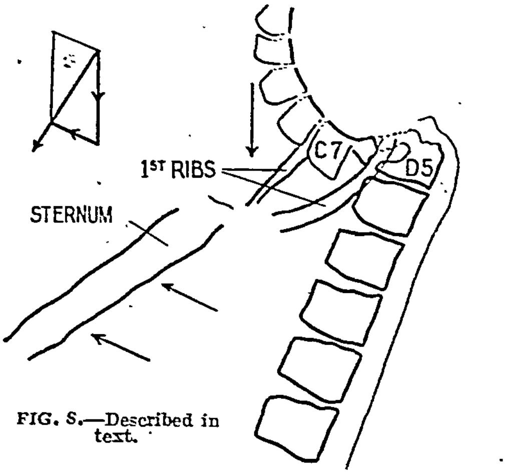

FIG. 8.—Described in text.

ANTERIOR LUXATION OF THE UPPER SEGMENT OF THE SPINE

In all cases where this condition was demonstrated the lesion was situated above the level of the sixth thoracic vertebra. It appears that "anterior luxation" is the characteristic deformity in severe high thoracic caries.

When the lower cervical and upper thoracic vertebræ have been destroyed, the cervical spine has no choice but to luxate anteriorly; it behaves in much the same way as the lumbar spine in spondylolisthesis, the only difference being that in the former the neural arches of the destroyed vertebræ are interposed and compel the cervical column to make its descent with ever-increasing angulation. If the lesion is a little lower —i.e., centred in the upper thoracic spine—an additional factor must be considered. During inspiration in the normal subject the upper end of the sternum moves very little on account of its firm anchorage to the vertebral column by the short immobile first ribs. If there is a solution of continuity in the upper thoracic spine and the first ribs are attached above the gap, it is possible for the whole sternum to be carried forward during inspiration (Fig. 8); its posterior anchorage is lost and through its attachment to the first ribs it can drag forward the segment of the spine above the lesion. It is clear from the diagram that the interaction of this force and gravity produces the characteristic deformity. Once this state of affairs has arisen, the deformity is likely to progress. The upper and lower segments of the spine can never come into adequate contact, consequently bony fusion cannot occur; indeed, there is often a gap between the two, filled only with fibrous tissue. Spontaneous bony fusion of the posterior elements occurs at the apex of the kyphos, but even if it were supplemented by extensive bone grafting, it is difficult to see how the strongest posterior fusion could support almost the whole of the weight of the head and neck.

POSTERIOR LUXATION

The deformity found in extensive lesions of the lower thoracic region is posterior luxation of the upper segment of the spine.

During inspiration in the normal subject the ribs and sternum are elevated, the antero-posterior and transverse diameters of the thorax are increased. Without describing the mechanism of respiration in detail it must be evident that it is only the relative rigidity of the vertebral column that prevents it from sharing in this otherwise symmetrical expansion of the thorax. If there is a gross defect in the thoracic spine there is no reason why the inspiratory force should not carry back the spine above the lesion in the same way that it carries the sternum forward (Fig. 9). The resultant of this force *In* with gravity *G* follows approximately the same path as that taken by the spine in "posterior luxation," and it is not unreasonable to suppose that this resultant force is the one producing the deformity. Whatever may be the exact cause of "posterior luxation" the frequency with which it occurs after extensive tuberculous lesions in the lower thoracic spine is in no doubt.

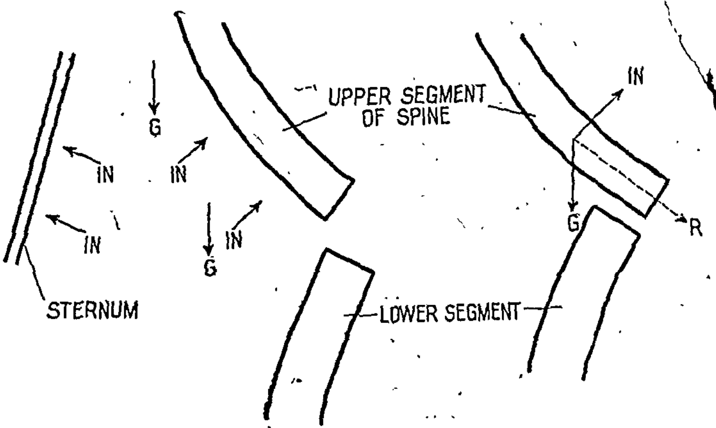

FIG. 9.—Described in text.

The prognosis as regards deformity is better in posterior luxation than in anterior luxation. There is no reason why bony fusion should not take place seeing that good contact between broad bony surfaces is generally present, and solid fusion is often found in spines showing posterior luxation.

Almost everyone has seen patients with severe deformity who lead active and useful lives—suffering, apparently, no inconvenience from marked anatomical changes in the spine and chest. Nevertheless certain serious conditions may arise in cases of gross deformity following thoracic caries.

1. A general lack of development is noticeable in many cases where the disease commenced early in life. In addition to the shortening resulting from the deformity of the spine, there is a definite general dwarfism.
2. There is a diminished resistance to chest infections, and an apparently trivial bronchitis may lead to death at an early age.
3. The cardiac efficiency is sometimes impaired and Carey Coombs has drawn attention to the association of severe kyphosis with sudden fatal cardiac failure.[7]
4. Intractable backache inevitably develops sooner or later in the movable segments of the spine, generally those below the lesion.
5. Lastly, a paraplegia of late onset, developing even 30 or 40 years after the active disease, is not uncommon in patients with severe deformity. In a series of 186 cases of Pott's paraplegia, Butler and I found that half of the cases fell into this group.[1] It is due either to reactivation of a small focus of disease in the spinal canal, or, less commonly, to involvement of the cord by bone. The important point is that late onset paraplegia is rarely found except in cases with gross deformity.

It must now be evident that, apart from the question of the patient's appearance, there is a strong case for every effort being made to reduce bone destruction during the active stage of caries of the thoracic spine.

Treatment

I propose to limit my remarks almost entirely to one form of conservative treatment—namely, rest in hyperextension. It appears to offer certain benefits not conferred by any other type of treatment, and as its value is by no means generally appreciated a revival of interest in this form of treatment is definitely called for.

The value of rest in the treatment of tuberculosis of joints, and particularly the spine, has slowly gained universal recognition since the days of Jean Pierre David. It is only in the methods employed for securing this end that differences are found between one school of surgeons and another. However, rest in hyperextension is a very definite departure from the beaten track, and it is necessary for us to inquire into the origin of this form of treatment.

Hyperextension of the spine in the treatment of Pott's disease first came into prominence towards the end of the last century when Calot introduced his operation of "redressement brusque"—forcible straightening of the deformed spine under anæsthesia. He did not advocate this operation as a form of treatment for the active disease, but rather as a means for correcting the deformity. Calot still believed in the value of rest, though probably not with the fervour that characterised David, Hilton, Hugh Owen Thomas, or Robert Jones. His aim was to hyperextend the spine to such an extent that the line of gravity would fall through the pedicles at the level of the lesion, thus producing stability even though a number of vertebral bodies were absent. We now know that this is impossible, at least in the thoracic region, and his successes must have been due to the production of good compensatory curves above and below the lesion. Calot reported some encouraging results, and such was his enthusiasm that surgeons all over Europe began to practise his operation.

Then came news of disasters following forcible correction of the deformed spine—sudden death, permanent paraplegia, and recrudescence of the disease being the most serious. Calot finally recognised that his operation, like most others, had its limitations, and he was compelled to modify his original technique to the point of "une douceur extrême." After enjoying a few years of extraordinary popularity "redressement brusque" ended its days in neglect and disrepute, but it led nevertheless to the recognition of a new and valuable principle in the treatment of spinal caries.

Following Calot, Goldthwait, Tunstall Taylor, and many others practised hyperextension in modified forms until finally a new conception of treatment by rest developed: why not nurse the early active case in hyperextension from the first, so that deformity with all its attendant evils could never develop? This was the beginning of the various forms of hyperextension apparatus in use to-day—the frames associated with the names of Bradford, Whitman, and Silver, and the ingenious appliances devised by Gauvain.

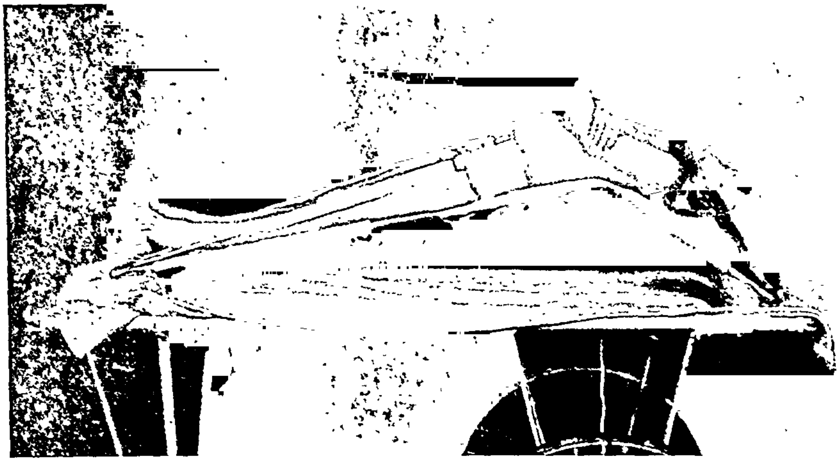

FIG. 10.—The Stanmore frame. The angulation is made exactly opposite the lesion. The pelvic band and head sling prevent longitudinal movement. The frame is no broader than the patient's trunk, and lateral movements are impossible. Almost the whole body surface is available for insolation.

Attractive as this may seem it is, however, a sad fact that a case of thoracic caries diagnosed early and treated from the first by hyperextension may lose several vertebral bodies. A gap in the spine is created, though it may only be demonstrable radiographically. It was the ambition of most of the early advocates of hyperextension to maintain the normal alignment of the spine even though several vertebral bodies might have disappeared during the course of the disease. They hoped to accomplish this during the healing or ambulatory stage by the application of a suitable jacket.

They had fallen into the same fundamental error as Calot, and this mistaken idea is responsible for the strong antagonism to treatment in hyperextension that is found in many quarters to-day. Pott believed that apposition and finally bony fusion of the involved vertebræ was the natural process of healing in spinal caries, and all our experience of tuberculosis of joints goes to confirm his view. Firm ankylosis, preferably bony, is, to use Pott's words, "the thing aimed at." Rest in hyperextension with any other end in view is entirely wrong.

However, rest in hyperextension may be assigned a most valuable place in the treatment of spinal caries on strictly orthodox lines, and I hope to show that it possesses certain merits not found in any other form of treatment.

Let us turn for a moment to the treatment of tuberculosis of the hip. In hip disease, as in spinal caries, bone destruction is the result of the activity of the disease, and of mechanical attrition of inflamed and softened bone brought about by the combined action of muscle spasm, movement, and weight-bearing. Tuberculous ulceration and mechanical ulceration of bone, to borrow Ménard's terms, are present in tuberculous disease of the hip and spine alike.

In the hip, mechanical ulceration can be almost entirely eliminated by combined traction and immobilisation, and Pugh has demonstrated very clearly that strong traction even in the absence of thorough immobilisation reduces bone destruction very considerably.

It is clear that immobilisation combined with powerful traction would be of the greatest possible value in the treatment of caries of the thoracic spine where bone destruction is often so extensive. Fixation does not present great difficulties, but powerful longitudinal traction for any length of time is out of the question. Yet the same effect may be obtained without difficulty, by hyperextension of the spine, provided that constant pressure is applied at the level of the lesion. We must aim at nothing less than the maintenance of a definite gap between the diseased surfaces; only in this way can the constant respiratory grinding be prevented from producing mechanical destruction of the vertebral bodies. That it is possible to produce such a gap is evident from radiograms.

ADVANTAGES OF REST IN HYPEREXTENSION

The peculiar virtues of rest in hyperextension are as follows:—

1. Bone destruction is reduced to a minimum; such destruction as does occur is due solely to the activity of the disease, a factor over which we have only a very limited control. I have been able to compare the bone loss in a number of cases of thoracic caries in children under treatment at the country branch of the Royal National Orthopædic Hospital, one group being treated by hyperextension, the other by simple recumbency. There is no doubt that the average number of vertebræ lost was less in the children treated in hyperextension than in the second series.

It has already been shown that the loss of a number of vertebral bodies results not only in the development of severe deformity of one or other of the types described but that cardiac inefficiency, lowered resistance of the lungs to infection, and late onset paraplegia must all be reckoned among the possible sequelæ of extensive thoracic disease. Treatment in hyperextension is the only measure known which aims directly at diminishing the incidence of these *complications.*

2. The accidents resulting from flexion of the spine during the active stage of the disease may all be prevented if hyperextension is begun early. Three conditions have been described: concertina collapse of a single body, the posterior displacement of sequestra, and pathological dislocation of the spine. It is admitted that these accidents are rare, but they are nevertheless of great importance for they are all capable of producing severe and generally permanent paraplegia.

3. The compensatory overgrowth phenomenon in children described by Johnstone has been noted only in cases treated in hyperextension. As this overgrowth has the effect of partially correcting such deformity as is present, everything must be done to encourage its development—another argument in favour of hyperextension. I am not yet in a position to say how frequently compensatory overgrowth occurs, but Johnstone who has devoted a number of years to the treatment of surgical tuberculosis has said that it is by no means uncommon.

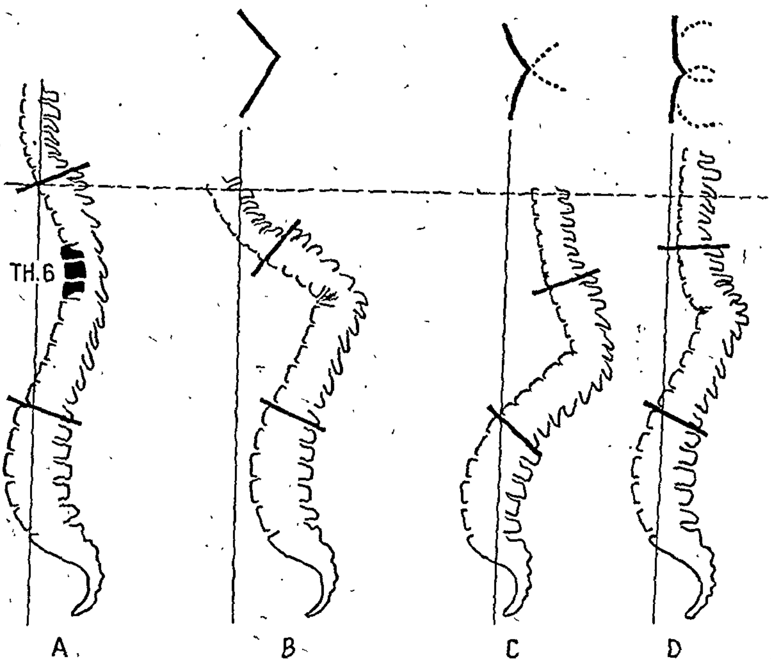

FIG. 11.—(A) Lesion involving body of Th. 6, and adjoining portions of Th. 5 and 7. (B) Uncompensated kyphosis. (C) Natural compensation. (D) Ideal compensation.

APPLICATION OF THE METHOD

What is the best form of hyperextension apparatus? There is no one answer to this question. Any apparatus complying with the conditions already laid down is satisfactory provided that it is used intelligently. I have found that the narrow gas-pipe frame as used by Whitman leaves little to be desired (Fig. 10).

For how long should hyperextension be continued? It is obvious that no change of treatment should be contemplated until there is definite evidence that the disease is becoming quiescent. As in tuberculosis of the hip, our main guide is the appearance of the lesion as seen in radiograms taken at regular intervals of three or four months. One maintains hyperextension until radiography shows, first, cessation of bone destruction over a period of about eight months; secondly, recalcification of the involved vertebræ; and thirdly, improvement in the definition of the bone where erosion has been taking place.

When these signs of quiescence are present (and it may be two or three years from the inception of treatment before they appear) it is time to allow the vertebræ to fall together and fuse. In most cases, in spite of our efforts, several vertebral bodies have been attacked and a definite gap is present. This must be allowed to close; it is the natural process of healing in this disease. The patient should be turned on to his face and nursed in an anterior shell. There is now nothing to prevent collapse at the level of the lesion, and an opportunity is provided for the development of the erector spinæ muscles which suffer considerably when a patient is immobilised for many months on a frame.

When good apposition of the diseased vertebræ has occurred (and it is easily demonstrated radiographically) many surgeons are satisfied that treatment in recumbency has come to an end. A brace is supplied and the patient is discharged from hospital.

But there is another phase of treatment, the development of compensatory curves—a form of treatment that has received more attention on the continent than it has in this country, although the valuable work of Pugh at Carshalton, Waldenstrom[8] in Stockholm, and Calvé[9] at Berck, was recognised long ago.

It is clear that the kyphotic spine tends to become more angulated under the influence of gravity the moment the patient begins to walk (Fig. 11). An increase in angulation means movement at the site of disease and crushing of the involved vertebræ, both extremely undesirable processes. The natural defence against increasing angulation is the development of compensatory lordoses above and below the lesion. Unfortunately the natural curves are often incomplete or even absent, particularly in the thoracic spine, and when such curves do appear they are always long and are segments of large circles. Furthermore, as Calvé has pointed out, and emphasised again recently,[10] the natural compensatory curves not only look ugly but result in considerable shortening of the trunk.

The effect of a compensatory curve is to shift the line of action of gravity posteriorly, so reducing the force acting on the arm of the lever formed by the segment of the spine above the lesion.

Butler is strongly of the opinion that an uncompensated spine is always liable to reactivation of the disease and the development of late onset paraplegia, and the case reports that he has collected seem to bear out his contention.[1]

Where bone destruction has been negligible the natural compensatory curves that develop when a patient is nursed on his face after the termination of hyperextension on a frame are quite adequate. In cases where bone destruction has been marked more active measures are necessary: short curves forming segments of small circles must be induced above and below the lesion. This may be accomplished by keeping the patient on the posterior frame, and placing thick pads of suitable material, such as spongy rubber, immediately above and below the kyphos, so as to produce curves in the most advantageous positions. Where a curve is required in the interscapular region, a central pad is used which presses on the spine between the scapulæ.

The lumbar and cervical curves are only too easy to produce; the difficulty is to produce a marked lordosis in the thoracic region, where one's efforts are resisted by the lack of extension normal to the thoracic spine, and by the rigidity of the thorax. But it can be done.

Let us suppose that the tuberculous focus is quiescent and that adequate curves have been developed above and below the lesion. How is this ideal position of the spine to be maintained? Most surgeons fit the child with a brace, and in many cases it is sufficient. Yet one is tempted to consider spinal fusion as a better form of treatment—a grafting operation designed not only to fix the affected vertebræ and their immediate neighbours, but extending to the adjoining parts of the compensatory curves. Waldenstrom [8] has pursued this policy for a number of years, even in children, and his results are most impressive. If we regard spinal fusion as the most perfect form of spinal support at our disposal, then we have here an admirable field for the operation worthy of wide exploration. Spinal fusion for active disease in children has been tried and found wanting, but it may well be that the operation will prove useful in rendering permanent the good results of conservative treatment.

THE ANEURYSM PHENOMENON

The condition that I have called the aneurysm phenomenon in thoracic caries generally passes unrecognised and consequently the question of special treatment is never considered. Ghormley seems to be the only surgeon who has taken the matter seriously, and he has discussed the possible indication for operation in cases where the condition is present.

He was of the opinion that collapse of all the eroded vertebræ would occur ultimately, even where no true secondary foci had appeared. Costo-transversectomy at an early stage was recommended to empty the abscess, so limiting its longitudinal spread and the depth of the mechanical erosion of the vertebræ adjoining the primary focus. If collapse of the eroded vertebræ does occur, then operation would certainly be justifiable. But in all of the 12 cases that I have followed, there was no suggestion of collapse in any single case. In one case of unusually deep erosion the child has been under constant observation for five years, and there has never been any sign of curvature except at the primary focus of disease. There is, therefore, no justification for interference in the purely aneurysmal type of destruction, and if spinal fusion is contemplated during the later stages of treatment the eroded vertebræ may be regarded as normal for the purposes of operative fixation.

But the possibility of secondary foci making their appearance suggests that the aneurysm phenomenon may after all call for operative intervention, and costo-transversectomy is the only operation that might be of value.

Yet we must remember that secondary foci appear only occasionally, and it would hardly seem right to subject all cases of aneurysmal erosion to costo-transversectomy for the sake of avoiding the secondary foci that might appear in a few cases if the operation were not performed. The conclusion is, therefore, that aneurysmal erosion does not call for any special treatment, but vigilance is required to detect the appearance of secondary foci: routine lateral radiography of the spine is the only means at our disposal for following the progress of this interesting complication of caries of the thoracic spine.

Much of the work embodied in this paper is based on the routine radiographic examination of a large number of cases, and I must express my thanks to my colleague Mr. C. W. Durward for the infinite pains that he has taken in the production of several hundred faultless X ray pictures.

CONTROL OF WHOOPING-COUGH WITH SERUM AND VACCINE

THE USES OF A NEW SKIN TEST

BY DONALD PATERSON, M.D. Edin., F.R.C.P. Lond.

PHYSICIAN FOR DISEASES OF CHILDREN, GREAT ORMOND-STREET AND WESTMINSTER HOSPITALS

R. H. BAILEY, M.B. Camb.

WANDER SCHOLAR AND REGISTRAR TO THE CHILDREN'S DEPARTMENT, WESTMINSTER HOSPITAL; AND

R. G. WALLER, M.R.C.S. Eng.

ASSISTANT PATHOLOGIST, WESTMINSTER HOSPITAL

THE object of this paper is to give a short review of efforts made during the past ten years to combat and control pertussis, and to put forward (1) a method of preventing the disease in susceptible contacts, and (2) a method of vaccination, controlled by skin test, which affords active immunity.

There are, on an average, 40,000 cases of whooping-cough [1] annually in London alone, and Stocks and Karn [2] maintain that "it is the most important epidemic disease in the great Metropolis in causing physical suffering, loss of school attendance, impairment of physique, and mortality." At its worst it is the cause of between 2000 and 3000 deaths per year in England and Wales.[3] Much work has been done in an attempt to control the disease, as has been done in the case of diphtheria and small-pox, but so far with small success. Methods of treatment are of two kinds:—

(1) Treatment *during an attack*, in an effort to alleviate the symptoms and shorten the course of the disease.

(2) Treatment by *prevention of an attack*, in an effort to immunise the child in infancy.

Treatment with Convalescent Serum

Various remedies have been tried for this acute disease, with little or no success. One worker, however, stands out, in that his line of approach was from a different angle. Jundell [4] in Stockholm aimed at procuring human serum with a high antibody content to treat children already infected with whooping-cough. His method was to raise the antibody titre in the serum of adults, who had had pertussis previously, by injecting three five-daily doses of whooping-cough vaccine, and bleeding them five days later. The serum was then given to the infected child, the total quantity being not less than 60 c.cm. Jundell [4] prefers to treat children in the catarrhal stage, or the first two days of the spasmodic stage, and in the five cases which he describes in detail all the children had fewer and milder paroxysms than the non-treated control children.

One of us (R. G. W.) working at the Westminster Hospital for the past four years, has made use of convalescent human serum, first in treatment and later in prophylaxis. In the treatment some 25 to 30 consecutive cases, which had been admitted to a fever hospital as clinical whooping-cough, received, on admission, doses of serum varying from 5 to 25 c.cm. No apparent improvement in the clinical condition, such as reduction in the number of whoops per 24 hours, occurred, nor was the total period of illness diminished. It is of interest to note that though these cases were unselected as regards the day of the disease, or severity of illness, none of the patients developed complications, and all recovered.

Prophylaxis with Serum

Since the therapeutic effect of convalescent serum was doubtful, it was decided to try convalescent serum as a prophylactic agent. At the time this portion of the work was undertaken it was not possible to select known susceptible cases on which to practise prophylaxis. Natural immunity was an unknown factor always to be considered.

The ideal method of approach seemed to be the selection of cases in families of children living under conditions of overcrowding. On the first diagnosis of the disease in one child, half the remainder of presumably susceptible children received serum, whilst the other half received no serum. This apparently ideal method did not, however, take into consideration the fact that those who received serum might be naturally immune, or already well advanced in the incubation stage. The results accordingly might well be inconclusive. Further difficulties were encountered, since the number of occasions on which a family was large enough for the satisfactory performance of this experiment was necessarily limited.

Where possible, this method, with controls in the same family, was employed, but there have of necessity been far greater opportunities of attempting prophylaxis in families of two children only. In these cases it was usual to find one child in the whooping stage, whilst the other presented no clinical evidence of the disease. In such cases it was the investigator's practice to give the unaffected child a dose of serum immediately the nature of the disease in the affected child was recognised. Since the incubation period of whooping-cough is a matter of speculation, but is probably in the neighbourhood of 14 days, one is always in doubt as to the stage of incubation which may already have been reached by a presumed susceptible who is to receive serum.

In a series of 95 definite "contacts"—not previously infected, as far as could be ascertained—between the ages of 1 month and 4 years, the majority of whom were not at any time satisfactorily segregated from the source of infection, treated with convalescent serum before there was any clinical evidence of whooping-cough :—

40 (42 %) did not develop the disease.
31 (32 %) developed the disease, but had a "mild" attack.
24 (26 %) developed the disease in an unmodified form.

In a series of "control contacts" in the same age-class, and similarly only partially segregated from the source of infection, and who did not receive serum :—

6 (11 %) did not develop the disease.
11 (20 %) had a "mild" attack.
38 (69 %) developed the disease in an unmodified form.

That is to say, 42 per cent. of patients receiving serum appear to have been fully protected against the disease, but it was not possible to say for certain whether this represents a higher proportion than that of the naturally immune portion of the child population, though it is a higher proportion than in the control series.

In the case of the 32 per cent. who developed the disease in a mild form, it was noted that the catarrhal stage began within ten days of receipt of the serum, and usually within a week. The disease was presumably approximately half-way through the incubation period before serum was administered.

The 26 per cent. of cases developing the disease in the unmodified form were represented by 21 patients to whom serum was given at the end of the incubation period, as evidenced by the fact that the disease was clinically recognisable within two days of receipt of the serum, and by 3 who had received serum early in the incubation period, as evidenced by the fact that the disease was not clinically recognisable until a fortnight or three weeks had elapsed. Again, it is of interest to note that no case developing the disease after serum injection developed complications or proved fatal.

Since this work has been carried out the development of an intracutaneous skin test suggests a modification which may usefully be employed in future investigations, and which would have materially enhanced the value of the preceding work; that is, the skin-testing of patients before administration of serum with a view to determining whether they are susceptible to pertussis, and after receipt of serum to determine whether they have become immune.

PREPARATION OF SERUM, DOSAGE, AND INJECTION

Blood was collected from convalescents not earlier than one week after all whooping had ceased, and preferably within a month of the termination of the illness. Serum was separated, and the sera from several cases were "pooled." The pooled serum was filtered through Seitz filters, and 0·5 per cent. phenol was added as preservative. The serum was then put up in 10 c.cm. ampoules and kept cool. Various doses have been employed, but it is now the practice to give 10 c.cm., irrespective of age, in one dose, deeply into the gluteal muscles. No untoward "reaction" has been observed to follow such treatment.

Prophylaxis with Vaccines

In 1921, one of us (D. P.)[8] conducted an investigation into 1000 cases, with James Smellie. Actually in 100 cases, those treated with vaccine (first injection containing 500 million, second injection 1000 million, third injection 2000 million, at weekly intervals) took longer to stop coughing and whooping than those cases of whooping-cough which were untreated.

Again in 1931, one of us (D. P.) took part in a large-scale investigation into the treatment of whooping-cough by a fresh vaccine prepared by Bordet himself. The investigation was undertaken by the Ministry of Health, who asked the London County Council, the Great Ormond-street Hospital, and St. Thomas's Hospital to coöperate. The results were uniformly unsatisfactory, those cases treated being as prolonged, or more prolonged, than those cases untreated. Some hundreds of children were injected.

Quite recently Stalling and Nichols [7] have reported good results with an active undenatured antigen.

Sauer [6] attempted to immunise children by the use of a vaccine, and in its preparation he observed that hæmolysis was more pronounced in the cultures of freshly isolated strains than in cultures of long standing. He therefore made a vaccine from fresh strongly hæmolytic strains of the Bordet-Gengou bacillus, grown on human blood for 48 hours, mixed with 0·5 per cent. phenolised physiological solution of sodium chloride. Sauer states that it is diluted so that 1 c.cm. equals 10,000 million bacilli. He injected 394 selected non-immune children, and gave a total of 7–8 c.cm. (70–80 thousand million bacilli), divided into three weekly injections. During five years the 31 *control children* in 24 of the families contracted whooping-cough, 29 of the injected children were exposed throughout the incubation, catarrhal, and paroxysmal period, but *none* contracted the disease. Although the dose Sauer gives is three times as strong as Madsen[9] gave, no marked local or general reaction occurred, and he believes the immunity is completed in four months, and lasts for years.

The Skin Test

Realising the importance of Sauer's work, and the possible potency of the vaccine prepared according to his directions, an effort has been made to produce a satisfactory test which could be used in the consulting-room to show—

(*a*) Whether a child has had an infection of the Bordet-Gengou bacilli, on some previous occasion.

(*b*) Whether specific treatment in a non-infected child had been of any avail after a course of injections.

To this end various efforts have been made. An agglutination test was first attempted, but proved inadequate, owing to the fact that human serum was used in the preparation of the vaccine, which completely distorted any results obtained, and also the test was considered too elaborate for most medical practitioners to perform. Marshall Findlay (Wellcome Laboratories), working in connexion with the authors, found that on immunising rhesus monkeys with Sauer's vaccine they gave a positive intracutaneous skin test 10 days after the second injection of vaccine. (The first injection of vaccine had been given 10 days previously.)

The vaccine is injected intradermally into the flexor surface of the forearm, the result being read at 24 and 48 hours. A positive test is seen as an area of hyperæmia around the site of the injection, ranging in size from a sixpence to a shilling in diameter. It is transitory in nature, and some experience is required to make accurate readings. It should be seen in 24 and 48 hours, and tends to disappear after this. Just as a marked reaction may be expected in adults with the Mantoux test, the same marked reaction may be expected in adults with this pertussis test, and smaller quantities, even 0·05 c.cm., will give a very definite positive.

THE TEST IN USE

Observations have been made on four groups of children—

(*a*) Seventeen children were seen in the catarrhal stage of whooping-cough, and gave a negative skin-test, but developed a positive skin-test later on in the disease. The following are examples:—

A. B. 3½ years. Cough for 14 days. Skin-tests: May 28th, negative; June 11th, positive.

C. D. 6 years. Cough began Dec. 11th, 1934. Vomited, whooped. Skin-test done at various intervals was negative. Became positive Jan. 1st, 1935, 4–5 weeks after infection.

(*b*) One hundred children were tested in the ward and at out-patients, some with a history of having had whooping-cough, and others with no such history. Of these, 52 cases gave a positive skin-test, and 48 a negative.

(1) 45% gave *negative* skin-test and had a *negative* whooping-cough history.

(2) 33% gave a *positive* skin-test and had a *positive* whooping-cough history.

(3) 3% gave a *negative* skin-test with a *positive* whooping-cough history.

(4) 19% gave a *positive* skin-test with a *negative* whooping-cough history.

(*c*) Seven children who gave no history of pertussis, but whose parents desired them to be immunised, gave a negative test before the injections with Sauer's vaccine, and developed a positive skin-test at a later date. The following are examples:—

I

Baby, aged 9 months. Negative skin-test.

Right arm (deltoid).	Jan. 8th..	1·0 c.cm.		
Left ,, ,,	,, 11th..	1·0 ,,		
Right ,, (triceps).	,, 15th..	1·5 ,,		
,, ,, ,,	,, 18th..	1·5 ,,		
,, ,, (biceps).	,, 22nd .	1·5 ,,		
,, ,, ,,	,, 25th..	1·5 ,,	=8 c.cm.	
Intracutaneous test.	Jan. 25th..	Positive.		

No effect on the child was noticed by the mother, except slight fretfulness on the night of the first injection.

II

Boy, aged 2 years 11 months. Negative skin-test.

Right arm (deltoid).	Jan. 11th..	1·0 c.cm.	
Left ,, ,,	,, 15th..	1·0 ,,	
Right ,, (biceps).	,, 18th..	1·5 ,,	
Left ,, ,,	,, 22nd .	1·5 ,,	
Right ,, (deltoid).	,, 25th..	1·5 ,,	
,, ,, ,,	,, 29th..	1·5 ,,	=8 c.cm.

Skin-test, Jan. 29th, positive; March 20th, positive.

III

Boy, aged 11 months.

Right arm (deltoid).	Jan. 11th..	1·0 c.cm.
Left ,, ,,	,, 15th..	1·0 ,,
Right ,, (biceps).	,, 18th..	1·5 ,,
Left ,, ,,	,, 22nd .	1·5 ,,
Right ,, (deltoid).	,, 29th..	1·5 ,,
Left ,, ,,	Feb. 2nd .	1·5 ,,

This child was under observation in Westminster Hospital for the whole course of the injections. After the first injection a rise of temperature was observed, and subsequently on each occasion, but less marked each time.

Skin-test: Feb. 5th, positive.
Blood count: Normal, after course of injections.

Recent inquiry revealed that none of the children who were vaccinated have come into contact with active pertussis up to the present time, nor have they developed the disease.

Technique of Immunisation

The procedure of active immunisation of suitable cases is as follows. It varies slightly from that recommended by Sauer in that three bi-weekly injections are made instead of three weekly ones. Alternate arms are used each time, the deltoid region being injected the first week, and the triceps region the second week, the deltoid region again being used the third week. The dose is—

1st injection	right deltoid	..	1·0	c.cm.	3 days later.
2nd ,,	left ,,	..	1·5	,,	4 ,,
3rd ,,	right triceps	..	1·5	,,	3 ,,
4th ,,	left ,,	..	1·5	,,	4 ,,
5th ,,	right deltoid	..	1·5	,,	3 ,,
6th ,,	left ,,	..	1·5	,,	
Total	.. ..	..	8·5	,,	=85 billion bacilli.

Skin-tests are performed before, during, and after the injection. The skin-tests became positive approximately one week after the last injection. This appears to show that, contrary to what Sauer claims for the vaccine, an allergic state is developed which gives a hypersensitiveness to the skin 3–4 weeks after the initial dose of vaccine, and the child then shows a positive skin-test. This gives the physician some idea as to whether or not the treatment is effective, and agrees with the result of vaccination in other diseases. Whether or not immunisation is complete then it is difficult to say. Possibly it reaches its height at four months, as Sauer suggests.

Summary

(1) Convalescent serum from cases of whooping-cough has been used with definite benefit in the prophylaxis, but doubtful benefit in the treatment, of pertussis. (2) A preliminary description is given of a skin-test which can be used both to diagnose whooping-cough in an early stage, and also to pick out those children who are susceptible to the disease. (3) The pertussis skin-test is further evidence that children can be immunised against whooping-cough by the giving of a suitable vaccine. (4) Children who give a negative skin-test can be made to give a positive skin-test by the injection of the vaccine.

Our thanks are due to Dr. Marshall Findlay and the Wellcome Laboratories for help with the experimental side of this investigation, and we are indebted to Dr. Findlay for demonstrating the intracutaneous pertussis test experimentally first on monkeys. We are also indebted to Eli Lilly and Co., Ltd., for supplying us with the necessary amount of Sauer's vaccine required in carrying out these tests.

THE "PREGNANCY" TEST IN RELATION TO DEATH OF THE OVUM

By P. M. F. Bishop, B.M. Oxon.

LECTURER IN CHEMICAL PHYSIOLOGY, GUY'S HOSPITAL MEDICAL SCHOOL; CLINICAL ASSISTANT TO THE OBSTETRIC DEPARTMENT, GUY'S HOSPITAL, LONDON

THE practical value of the Aschheim-Zondek and of the Friedman tests for pregnancy is now clearly established. In the diagnosis of uncomplicated pregnancy the tests are extremely reliable and most workers report an accuracy of about 98 per cent. The test has also been employed in the diagnosis of hydatidiform mole and chorion-epithelioma, both of which conditions give very strong pregnancy reactions, as little as 1/2000 of the normal dose of urine being required in some cases to give a positive result. Recently studies have been made on the hormone content of the blood and urine in connexion with certain complications of pregnancy, such as hyperemesis, toxæmia, and eclampsia.

It is therefore natural that the clinician should now appeal to the laboratory worker to assist him in diagnosing death of the fœtus in utero.

Of what value are the biological tests for pregnancy in the diagnosis of intra-uterine death? How long after the death of the fœtus do the tests remain positive? The present communication is an attempt to solve this question. It summarises the results given by the test in a consecutive series of cases in which the date of fœtal death could be determined clinically with some degree of certainty.

The Friedman test was employed in all the cases of the present series. The method of performing the test has been described in detail elsewhere (Bishop, 1933), and will therefore be briefly summarised only:—

An adult doe rabbit which has been segregated for 24 hours is submitted to abdominal laparotomy for inspection of the ovaries. 10 c.cm. of filtered urine for diagnosis is injected intravenously in a single dose. After a minimal interval of 36 hours the ovaries are again inspected by laparotomy. Three possible changes may occur, either singly or in combination: (1) increase in size and prominence of pre-existing ripe Graafian follicles; (2) the appearance of fresh corpora lutea; (3) hæmorrhage into unruptured follicles, the so-called corpora hæmorrhagica. The first of these changes represents a weak positive result. Should either or both of the other reactions occur the result is definitely positive. If none of the changes occurs 10 c.cm. of urine obtained from a woman known to be pregnant are injected intravenously, and again, after a minimal interval of 36 hours, the rabbit is submitted to operation and the ovaries inspected. If the typical changes are present it has been shown that the rabbit will react to urine of pregnancy, and the test can be confidently reported as being negative. If the ovaries still remain unchanged it is obvious that the particular animal employed is resistant to urine of pregnancy, and it is therefore discarded as being an unsuitable test animal, and the procedure is repeated on another rabbit. This modification of the original Friedman technique is designed to eliminate the rabbit as a source of error in the test.

The series is summarised in the accompanying Table. It will be seen that on two occasions (Cases 2 and 5) the test was still positive six weeks after death of the fœtus. Apart from these two cases the test tends to become negative between 10 and 24 days after intra-uterine death has taken place.

Table giving Summary of Cases

No.	Interval between death of ovum and performance of test.	Result of test.	Interval between death of ovum and expulsion or delivery.	Stage of pregnancy at which ovum died.	Condition of placenta and remarks.
1	3 d.	P.	3 d.	7 m.	Placenta 4 lb. Very bulky and pale. Section: active chorionic tissue. Fœtal ascites.
2	6 w.	P.	10 w.	6 m.	—
3	1 w. 3½ w.	P. N.	5 w.	—	— —
4	9 w.	N.	—	4½ m.	—
5	6 w.	P.	—	5 m.	—
6	6 d.	P.	—	—	—
7	14 d. 21 d. 28 d. 35 d.	W.p. W.p. N. N.	52 d.	8 m.	Placenta completely infarcted. Hormone excretion normal at fifth month.
8	10 d.	P.	10 d.	8 m.	Placenta normal. Section: active chorionic tissue.
9	8 w.	N.	8 w.	5½ m.	No gross infarction. Healthy villi. Some degeneration of connective tissue.
10	36 h.	W.p.	6 w.	—	—
11	47 d. 56 d.	N. N.	72 d.	6 m.	Grossly infarcted.

W.p. = weak positive; N. = negative; h., d., w., m. = hours days, weeks, months.

These observations are supported by the reports of other workers (see bibliography). I have been able to find reports of only 31 cases in which the exact date of fœtal death was determined clinically. In most of these the Aschheim-Zondek rather than the Friedman test was performed, and many of the tests were positive as long as 40 days after death of the ovum. The reason why the Aschheim-Zondek test remains positive rather longer than the Friedman test is because infantile mice are more sensitive to prolan of pregnancy urine than adult rabbits, and will therefore detect smaller concentrations of the material. For instance, in normal pregnancy the Friedman test becomes negative within 48 hours of parturition (Bishop), whereas the Aschheim-Zondek test usually takes about 7 days (Aschheim).

Both Aschheim and Bulliard report cases in which the test was positive three months after fœtal death.

Bué, Palliez, and Gernez describe a case in which the test was positive 10 weeks after the fœtus had died at 3½ months.

Brouha and Hinglais, using infantile male mice as the test animals, obtained a positive result 2 months after death of the ovum.

Stewart investigated a case by the Aschheim-Zondek method, and found a positive reaction 1–2 months after the ovum had died.

Runge and Clausnitzer made very complete quantitative observations on the hormone content of the urine in two cases of intra-uterine death. They report that both the œstrin and the gonadotropic hormone concentrations are considerably less than they are at the same period before normal parturition, but that the œstrin level falls very much more rapidly than the gonadotropic hormone level.

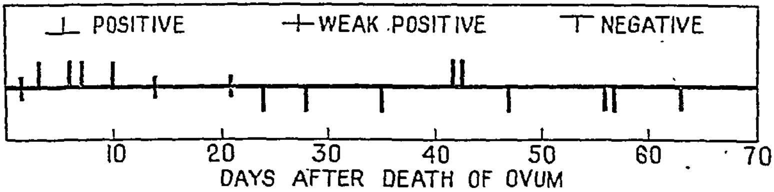

Chart showing 16 reactions obtained in 11 consecutive cases in which the date of the death of the ovum was known.

Westman investigated a case of intra-uterine death of a 7 months' fœtus. Immediately after the death of the fœtus the patient developed rapidly progressive signs of a pregnancy toxæmia. Three weeks after the fœtal movements had ceased to be felt an Aschheim-Zondek test was positive. Six days later a macerated fœtus was delivered by Cæsarean section, and the placenta was examined histologically. Apart from some thrombosis of the stromal vessels the tissue appeared normally active. Implants of the placental tissue were made into infantile mice, as the result of which a fairly strong œstrin reaction developed in the uterine horns, but there was no evidence of ovarian stimulation. From this it appeared that though œstrin was still present in the placenta, the gonadotropic hormones had completely disappeared. Westman suggests that the anterior pituitary had taken over the secretion of the gonadotropic hormones at the time of fœtal death. This would explain the positive Aschheim-Zondek reaction in the urine and the negative reaction with the placental implants. He further postulates that the pituitary may continue to elaborate an excess of gonadotropic hormones for some time after death of the fœtus, so that the urinary Aschheim-Zondek reaction is relatively slow in becoming negative as compared with the rapid disappearance of œstrin.

Spielman, Goldberger, and Frank report a series of 33 cases, but in only 12 of them does the exact date of fœtal death appear to have been clinically determined. In most of the cases both the œstrin and the Aschheim-Zondek tests were performed, the former becoming negative much earlier than the latter, though on one occasion the œstrin test was still positive 23 days after fœtal death.

DISCUSSION

The subject under review is of importance not only from the practical point of view but also from the scientific standpoint. There is sufficient evidence to make it clear that during pregnancy the placenta takes over the function of the anterior pituitary and elaborates a gonadotropic substance, the excess of which is excreted in the urine. That the tissue responsible for the secretion of this factor is the chorionic villus is shown by the fact that in hydatidiform mole the amount of hormone excreted is hundreds of times more than in normal pregnancy. Furthermore, this enormously increased excretion may occur even in the absence of pregnancy, as in the case of chorion-epithelioma, either in the female or in the testis of the male. It would appear, therefore, that the Aschheim-Zondek and Friedman tests depend primarily on the *presence or absence of functional chorionic tissue* and *not on the life or death of the ovum*. Since, however, the main function of the placenta is to provide a means of nourishing the living embryo, one would expect it to become inactive on the death of that embryo. Aschheim states that the factor responsible for a positive "pregnancy" reaction is the biological contact between the maternal blood and the chorion-epithelium; but this is not always true. It is quite common to get a moderately severe post-partum hæmorrhage after the abortion or delivery of a macerated fœtus, showing that there is an adequate maternal circulation in the intervillous spaces, and in some of these cases the pregnancy test at the time of delivery has been negative. For instance in Case 9 the patient had a post-partum hæmorrhage of a pint. Furthermore, the strength of the pregnancy reaction is not necessarily proportional to the amount of placental tissue. In normal pregnancy the reaction is stronger in the earlier months when the placenta is small and growing than it is towards term, when the placenta is fully grown and bulky. Finally, the activity of the chorionic tissue, as measured by the pregnancy reaction is not necessarily reflected in its microscopical appearance. It is quite possible for the pregnancy reaction to be negative in the presence of apparently healthy villi, as seen under the microscope. This occurred also in Case 9, and on another occasion I obtained a negative Friedman test in a case of retained products, where quite a large piece of placenta had shown perfectly healthy villi in contact with the maternal circulation.

The results cited in this paper make it clear that there is no direct relation between the death of the ovum and the disappearance of gonadotropic substance from the urine, nor should we expect this to be so, on theoretical grounds, for there is no reason to suppose that the fœtus itself produces the gonadotropic factor. Furthermore, the time after the death of the ovum at which the placenta ceases to elaborate the gonadotropic hormone seems to vary considerably in individual cases, and to be determined by no mechanism so far understood. Westman's theory that the anterior pituitary takes over the function of secreting the gonadotropic factor from the placenta immediately after the death of the embryo is interesting, but is not, to my mind, proved by the case which he has studied. In this case 6 days intervened between the collection of the sample of urine which gave a positive Aschheim-Zondek reaction and the implantation of the placental tissue into the infantile mice, which resulted in no ovarian stimulation. Had a second specimen of urine been taken at the time of the Cæsarean section, and had it again given a positive Aschheim-Zondek reaction, Westman's case might have been more convincing. His theory requires thorough experimental investigation before it can be accepted.

CONCLUSIONS

(1) Where intra-uterine death is suspected clinically, a negative pregnancy reaction will confirm this suspicion; but a positive reaction may still occur as long as three months after the death of the ovum, and cannot therefore be accepted as showing that the fœtus is still alive. (2) A comparison between the œstrin reaction and the Aschheim-Zondek and Friedman tests shows that the former becomes negative considerably sooner after fœtal death than the latter. It may, however, still be positive three weeks after death of the ovum, so that a positive result is by no means certain evidence of a living embryo. (3) The results obtained in the cases investigated throw no fresh light on the factors which regulate the secretion of gonadotropic hormones by the placenta.

I am indebted to Mr. G. F. Gibberd, assistant obstetric surgeon to Guy's Hospital, for the interest he has taken in this work, for supplying me with the clinical details of some of my cases, and for having the placenta histologically examined in a number of the cases.

THROMBO-ANGIITIS OBLITERANS

(BUERGER'S DISEASE)

GASSING AS AN ÆTIOLOGICAL FACTOR

By J. B. McDougall, M.D. Glasg., F.R.C.P. Edin. F.R.S.E.

MEDICAL DIRECTOR, PRESTON HALL, KENT; AND

J. H. Crawford, M.B. Leeds

ASSISTANT MEDICAL OFFICER, PRESTON HALL

The following case was referred to us because the patient thought of claiming a pension for thrombo-angiitis obliterans on the ground that it was a disability arising from gassing.

He was a man aged 44 at the time of examination in May, 1934, and he had always enjoyed good health until joining the Army in 1914, at which time he was classed as A1. In 1915 he was severely gassed, and after this he suffered considerably from a troublesome cough and increasing breathlessness. On his discharge from the Army in 1919, he attempted to continue at his former work as a bricklayer but had to give up because of his cough and breathlessness, and in 1922 he obtained a pension for bronchitis as "a permanent disability resulting from his gassing." About this time he developed cramp-like pains in the calf of his right leg, with numbness and coldness of the toes. These symptoms were apparently worse in cold weather and also after resting. With the passage of time the symptoms became progressively more marked, and in 1924 he developed an ulcer under the nail of the second right toe which proved resistant to treatment and became septic, the toe having to be amputated in October, 1924. The amputation wound never healed satisfactorily. The Wassermann reaction of both blood and cerebro-spinal fluid was negative; tubercle bacilli were never found in the sputum and tissue examination for tuberculosis and leprosy also proved negative.

In October, 1928, the third toe of the right foot was amputated for gangrene, and in December of the same year the limb had to be amputated above the knee because of extension of the gangrene up the leg. The amputated limb was sent for full pathological examination and the report confirmed the diagnosis of thrombo-angiitis obliterans. The left leg became involved in a similar manner, and in April, 1931, amputation above the knee was carried out.

On examination in 1934 he was found to be in fair general health only. The pulse-rate taken at the precordium was 84 per minute. No radial pulse could be made out on the right side and the pulse on the left side was only just palpable, and easily obliterated with slight pressure; the vessel wall was somwhat thickened. The blood pressure on the right side was 124/66, and on the left was 140/78. The pupils were equal in size and shape and reacted to light and accommodation. There was no conspicuous sepsis in the teeth or gums. An interesting feature was the presence of multiple lipomata on the right arm and back. There was discoloration and dystrophy of the nails of the right hand with trophic changes at the bases, these being most marked on the little finger where there was also some superadded sepsis. Both hands were cold and cyanosed.

The chest was well covered, with no definite impairment of the percussion note on either side. Breath sounds were a little harsh at the apices, but no adventitious sounds were heard. A good deal of bronchitis was present on both sides of the chest, and even on rest there was a good deal of dyspnœa. The veins of the face and neck were somewhat dilated. The X ray picture of the chest showed no pulmonary infiltration due to tuberculosis, but there was increased translucency over both sides due to a considerable degree of emphysema. The heart sounds were normal except for some accentuation of the second sound at the pulmonary area. Abdominal examination was negative and the urine was normal. The patient has no foreign blood in his veins, and is neither a heavy smoker, nor a heavy drinker.

The diagnosis was clearly chronic bronchitis and emphysema following gassing, with thrombo-angiitis obliterans as a complication.

ÆTIOLOGY OF THROMBO-ANGIITIS OBLITERANS

Thrombo-angiitis obliterans was first fully described by Buerger[1] in 1908 and he suggested the name by which it is now known. His monograph on this and allied conditions (the "Circulatory Disturbances of the Extremities," Philadelphia, 1925) is probably the most comprehensive work on the subject. According to him, thrombo-angiitis obliterans is a condition manifesting itself most usually by indefinite or cramp-like pains in the leg, trophic disturbances, and a discoloration of the limb.

As a result of careful study on the pathology of the condition, he described three stages in the progress of the disease.

(a) A stage of acute inflammation of the vessels, the inflammatory process involving particularly the deeply situated and larger arteries and veins of the lower and upper extremities, and being rapidly followed by an extensive occlusive thrombosis.

(b) A stage of healing or organisation, characterised by the gradual disappearance of the inflammatory products.

(c) A final stage in which fibrosis of the adventitia occurred and the vessel was converted into a fibrous cord.

Thus the final result is the obliteration of arteries and veins over a large part of their course by vascularised and canalised connective tissue.

Despite the increasing attention which of late has been paid to this condition, with the subsequent clarification of its pathological features, its ætiology remains obscure. Brown, Allen, and Mahorner[2] show that the cause has been laid successively at the door of tobacco-smoking, the Hebrew race, the male sex, exposure to cold, a shortened coagulation time of the blood, and various nutritional deficiences. Meyer[3] even cites a particular birthplace as a causative factor of importance, believing that patients coming from the belt of land between the Black Sea and the Baltic Sea were particularly liable to this disease.

More important than any of these, however, is the rôle of infection. In Brown, Allen, and Mahorner's series of over 300 cases,[2] the Wassermann reaction was positive in 3 per cent. Evans[4] reports, as leading factors, the occurrence of dental sepsis, nose and throat infections, tuberculosis, prostatitis, typhoid, amœbiasis, and other chronic gastro-intestinal infections. No specific infectious agent has been isolated bacteriologically. Rabinowitz[5] has described an organism which on injection into a rabbit produced an auricular thrombus, but this work has not been confirmed and organisms are not often found in either the acute, subacute, or chronic stages. One is therefore forced to the conclusion that of the many ætiological agents which have been suggested, none fulfils the requirements of a direct causal factor.

A new method of approach to the problem was suggested by Riesman[6] in a lecture on phlebitis and thrombosis. He said, "Barcroft and other English physiologists have shown the fundamental importance of oxygen for the life of the tissues. May not, in Buerger's disease, a lack of oxygen be as important an element in the devitalisation of the tissues as the lack of non-gaseous constituents of the blood?" Meakins and Davies[7] have shown that gas-poisoning provides an example of severe and progressive oxygen-want. These workers have shown that this result, in particular, follows gas-poisoning with phosgene, which liberates hydrochloric acid in the alveoli, with a resultant local necrotic action on the alveolar epithelium and the production of an insidious œdema. Owing to its greater solubility, carbon dioxide passes out more readily than oxygen passes in—and thus a condition of progressive oxygen-want is produced. With a more severe action of phosgene in those exposed to larger and more concentrated doses, there is produced an actual necrosis of the cells with thrombosis of the capillaries. In such cases, oxygen-want becomes well marked. Meakins and Davies[7] have also shown that oxygen-want is a characteristic feature of such conditions as emphysema, chronic bronchitis, pulmonary fibrosis and chronic bronchiolitis—conditions seen in the end-results of gassing.

RELATIONSHIP BETWEEN GASSING AND THROMBO-VASCULAR LESIONS

In emphasising the importance of gassing in the production of thrombotic vascular lesions, the occurrence of such lesions both as an immediate and as a remote result may be noted. Thandavaroyan[8] reports a case of gangrene of the extremity following carbon monoxide poisoning, and a similar case is reported by Briggs.[9] Reidell mentions a case of gangrene of the leg following poisoning with illuminating gas.[10] But on the whole, extensive vascular thromboses as an immediate effect of gas-poisoning are rare, and most of the cases reported are of such lesions as a remote sequel of gassing. Thus Cole,[11] in a study of the remote effects of gassing, is struck by the fact that patients who recovered often showed gangrene of the extremities and various thrombotic tendencies throughout the body. This work was confirmed by Koch,[12] who made a careful study of autopsy material furnished by German soldiers who had been severely gassed and then died some years later. He found that thrombi were particularly liable to form in the femoral veins, the cardiac vessels, and the heart.

The consideration of the formation of thrombi as a particular sequel to gas-poisoning may be taken under three headings.

(a) *Alteration in the constituents of the blood.*—The large amount of hæmatin present in the circulating blood after gas-poisoning (particularly after phosgene) is a well-recognised fact, and according to Mayer[13] this is due to the effect of hydrochloric acid produced by the breaking down of the phosgene, as mentioned above. Vedder,[14] in a monograph on the medical aspects of chemical warfare, reports that at the height of gas-poisoning, the erythrocyte count in man was found to be well over 9,000,000. The same polycythæmia occurred experimentally in animals. The peripheral vessels are markedly contracted and the thickened blood flows feebly at the height of poisoning. A similar polycythæmia and also a marked increase in the hæmoglobin percentage was found by Barcroft and his co-workers[15] in their studies of chronic cases of gas-poisoning.

(b) *Slowing of the blood stream.*—This is noted as a secondary result to the increase in cellular content of the blood. Buerger[16] considers that the increased viscosity of the blood is one of the most important pathological results of gas-poisoning, and believes that it is partly due to the increased carbon dioxide content of the blood which produces a certain degree of swelling of the red blood corpuscles. Hergt[17] considers that the tendency to thrombosis is due to the increased concentration of the blood (Bluteindickung), the heightened coagulability, and the retardation of the blood flow.

(c) *Damage to endothelial tissue.*—The development of pulmonary œdema was referred to in the work of Meakins and Davies, and Gilchrist and Matz[18] have shown this œdema to be due to local injury of the endothelial cells which results in an increased capillary permeability. The actual mechanism in the production of the œdema is due to the increased permeability in association with the acid reaction produced by the hydrolysis of the phosgene.

Thus we see how the three main factors in the production of thrombi—viz., alteration in the constituents of the blood, slowing of the blood stream, and damage to the endothelial cells—are all intimate parts of the sequelæ of gassing.

In the case described, syphilis, tuberculosis, leprosy, gastro-intestinal disease, chronic naso-pharyngeal sepsis, and dental sepsis were all absent. The only factor left which could have produced the pathological changes in the patient's vascular tree described above, was the gassing which he sustained whilst on service, with the subsequent development of chronic respiratory disease, and we are of the opinion that the action of gassing, both directly and remotely, was an effective contributing agent in the production of the vascular lesion.

SUMMARY

1. A case of chronic bronchitis and emphysema following gassing, with subsequent development of thrombo-angiitis obliterans, is described. (2) The general ætiology of thrombo-angiitis obliterans is discussed. (3) The influence of gassing in the production of thrombotic vascular lesions is shown.

We wish to express our gratitude to Dr. L. Buerger, of New York, for his kind coöperation in this case, and for the trouble he has taken, despite his illness, to send us a lengthy personal communication in support of the view which we have advanced.

THROMBOSIS OF THE PAMPINIFORM PLEXUS

BY DONALD MCGAVIN, M.B. Camb., F.R.C.S. Eng.

DEMONSTRATOR OF PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL, LONDON

THROMBOSIS of the pampiniform plexus is a well-recognised result of injury or infection, but its apparently spontaneous occurrence is not so familiar. The condition is certainly not common, for, in searching the records of the surgical unit of St. Bartholomew's Hospital from 1921 to 1934, inclusive, and those of all surgical cases admitted to the same hospital from 1921 to 1928, reports of only two cases could be found. This probably under-estimates its true incidence, since, as it is rarely suspected, a certain number of cases will not have been recorded. The two following histories are reported here not only because well-authenticated examples of thrombosis of the pampiniform plexus are not common, but because the sufferers are liable to be treated by orchidectomy.

CASE 1.—A meat porter, aged 41, was admitted under Prof. G. E. Gask on April 10th, 1928. Five weeks before admission he began to feel pain in his left testicle, and this pain was increased by coughing or by lifting heavy weights, but was not affected by prolonged standing. It became worse during the first few days after the onset, then remained at about the same intensity.

During the five weeks before admission the patient had been kept under observation by his own doctor who noticed a moderate swelling in the left side of the scrotum, which had become smaller by the time he came to hospital. There had been no micturition symptoms, no cough, no night sweats, no weakness and no loss of weight.

On examination there was a hard, nodular swelling, slightly tender, of the globus major of the left epididymis. The body of the testis was normal. The vas was a little thickened but not beaded and there was no thickening of the spermatic cord. On rectal examination the left side of the prostrate was felt to be rather larger than the right, but there was no other abnormality. The patient was apyrexial, his urine was normal and general examination revealed nothing of note.

Although on consultation a diagnosis of tuberculous epididymitis was made, Mr. Paterson Ross, who was the surgeon in charge of the case, said that the short history, the diminution in size, the affection of the head of the epididymis without the tail and the absence of swelling of the left seminal vesicle made him doubtful. Orchidectomy was performed, when the epididymis and the body of the testis were seen to be macroscopically normal. At the lower end of the spermatic cord, in contact with the epididymis, was a mass of fibrous tissue apparently connected with the pampiniform plexus. Microscopical section showed a mass of fibrous tissue surrounding vessels of the spermatic cord. The walls of these vessels were thickened and they contained organised blood-clot. In the epididymis some tubules were normal and some showed in their cells dark brown granules which may have been altered hæmoglobin. There was no evidence of tuberculosis.

The patient was discharged with the wound soundly healed on the eighteenth day after operation.

CASE 2.—A shopkeeper, aged 57, was admitted under Mr. R. M. Vick on Jan. 22nd, 1935. Four weeks before admission there had been a sudden onset of severe pain in the left testicle. The pain radiated from the region of the left anterior superior iliac spine down to the scrotum, but did not go up to the back. *There had been no injury.* The pain was brought on by standing and was relieved by rest.

The patient had lost one stone in weight during the preceding year. He had no other symptoms of disease. On examination the body of the testis was found to be normal, with normal testicular sensation. The epididymis was moderately enlarged and was hard. The spermatic cord was thickened and nodular. There was no tenderness; no hydrocele was present. Rectal examination showed no abnormality. The patient was apyrexial and nothing of importance was revealed by the general examination.

A provisional diagnosis of tuberculous epididymitis was made, although the patient's age was thought to be against it and the condition was not considered typical. Orchidectomy was performed.

The gross specimen showed the body of the testis to be a little larger than normal. The epididymis and vas were normal, spermatozoa being recovered in large numbers from the latter. The veins of the pampiniform plexus were extensively thrombosed and their walls were thickened and varicose. In microscopical sections the testicle and epididymis were seen to be normal. The veins in the spermatic cord were much dilated and the largest of them was thrombosed, the clot being of varying ages. Beside the oldest part of this thrombosis the vein wall was completely destroyed and in that area there was organisation and recanalisation of the clot. The opposite region of the vein wall showed no abnormality and had no clot attached to it. *Most of the arteries showed intimal proliferation and fatty changes.* The vas was healthy and spermatogenesis appeared to be normal. The patient was discharged with the wound healed on the ninth day after operation.

DISCUSSION

Although no conclusions can be drawn from two cases, certain points may be noted. Both patients were of middle age, and in both the left side was affected. In neither was there an obvious exciting cause, such as trauma or infection, nor had there been any history of preceding varicocele or an abnormal position of the testicle. In neither case were the seminal vesicles diseased, nor were there firm nodules or softened areas in the prostrate. Active spermatogenesis was proceeding in one case and there was no reason to believe that it had been stopped in the other. Microscopically the walls of the vessels in both spermatic cords gave evidence of degeneration. The pain of one patient was of sudden onset, whereas that of the other began more gradually. The pain of the one was brought on by standing, while that of the other was not affected by standing although increased by coughing or lifting.

The differential diagnoses to be considered depend upon the stage at which the patient is first seen.

If he is examined soon after the onset, epididymo-orchitis is most likely to be simulated, whether gonococcal, coliform or the uncommon acute tuberculous type. Torsion of the spermatic cord may be suggested although in the thrombosis there would not be the associated shock and the testis would be well in the scrotum and not acutely tender. A diffuse hæmatocele of the cord would give a history of sudden onset of severe pain during some effort. Those cases which are seen a few weeks after the onset are liable to be diagnosed as tuberculous epididymo-orchitis. In these the mode of onset, the short history, the absence of any beading of the vas, and the negative rectal examination would be valuable points. The probable freedom of the tail of the epididymis from involvement may also be useful, but a hæmatogenous tuberculous epididymitis starting in the head is a possibility that impairs the value of this criterion. These later cases may occasionally resemble malignant disease of the epididymis. Mr. Russell Howard[1] mentions such a case and he has kindly supplied me with such details as can now be discovered. The man was a patient of Jonathan Hutchinson, junior, and there was an acute onset with symptoms resembling an epididymo-orchitis. After the acute stage had passed a hard lump remained just over the body of the testis. A sarcoma was diagnosed and orchidectomy performed. The specimen is now in the museum of the London Hospital (Genito-Urinary Section, No. 1584), and clinically this case resembled the first history reported in this paper.

The importance of recognising a thrombosis of the pampiniform plexus lies in its bearing upon treatment. Should it be confused with certain other diseases there is a possibility of an unnecessary orchidectomy. This is especially to be avoided, since the microscopical appearances reported here suggest that active function continues in the testicle on the affected side.

I wish to thank Prof. Gask, Mr. Vick, and Mr. Russell Howard for permission to use their cases, and Mr. Reginald Payne for kind assistance.

CONGENITAL MALARIA

WITH REPORT OF A CASE IN ONE OF TWINS

By N. Cecil Tanner, M.B. Brist., F.R.C.S. Eng.
ASSISTANT MEDICAL OFFICER, HIGHGATE HOSPITAL; AND
R. F. L. Hewlett, M.R.C.S. Eng.
ASSISTANT PATHOLOGIST, ARCHWAY GROUP LABORATORY, LONDON COUNTY COUNCIL

Although, rare the occurrence of congenital malaria appears to have been proved. Non-congenital malaria in infants is very common; in the hyperendemic areas of Senegal, M. Adam concluded from his observations that every child was infected by the age of three. Congenital infection has been proved in two ways, either by finding plasmodium in the blood of the child immediately after birth, or by demonstrating it in the blood of the offspring of malarious mothers born in non-malarial districts. In the case to be described the child was born in London, and so comes under the latter heading. A case of congenital malaria occurring in England was recorded in 1924 by Llewellyn Jones and Brown,[1] when a child developed pyrexia, associated with the presence of benign tertian parasites in the blood on the sixteenth day after birth. Our case is of particular interest in that it occurred in one of twins, and we have been unable to find any previous similar record.

CASE REPORT

The infant was the second born of dizygotic twins, born at St. Pancras Hospital on Jan. 14th, 1935. The parents were a Bengali, aged 28, and an Englishwoman, aged 25. They went to live in the Rajshi district of Bengal in 1931, and the mother had her first attack of malaria in October of that year. She has had repeated attacks since, the last being in March, 1935. They had five children, the two eldest, aged seven and five, had acquired malaria in Bengal. The third, born in October, 1933, died 12 hours after birth—the mother described it as being "born with malaria, stone cold, but with its head hot and sweating." No blood examination of this child was made. *During the whole of this pregnancy, the* mother stated that she was never free from malaria.

The mother returned to England in September, 1934, during her last and twin pregnancy. During pregnancy she had one or two attacks of malaria nearly every month, the last being ten days before delivery. She suffered from slight swelling of the feet, but no other symptoms or signs of pregnancy toxæmia. She suffered no abdominal trauma or pain, and there was no evidence of concealed or evident accidental placental hæmorrhage. The labour took place in St. Pancras Hospital and was uneventful; the first born was a male (weighing 6 lb. 7 oz.) and had the fairer complexion. The second, a female, weighed 6 lb. 11 oz., and was darker, with Indian features. Both appeared to be healthy. Obstetric forceps were not used, there was no undue post-partum hæmorrhage, and no bruising of the babies was noticed. No injections of maternal blood were made into the children. Both were breast-fed for 12 days and then bottle-fed.

The female child was admitted to Highgate Hospital under the care of one of us (N. C. T.) at the age of 50 days, with a history of "crying and doubling up its legs" for four days. It had not been feverish, nor had it had any rigors. Though heavier at birth, it was now lighter and shorter than the male twin (it weighed 6 lb. 12 oz.). The child was pale. The spleen was enlarged to 4 cm. below the costal margin.

Blood examination on March 8th, 1935, revealed the following: red cells, 2,310,000 per c.mm.; white cells, 6800 (polymorph, 10 per cent.; lymphocytes, 88 per cent.; large mononuclear, 2 per cent.). Parasites of benign tertian malaria were seen. The van den Bergh test gave negative direct and indirect results. Wassermann and Kahn reactions were both negative. No active treatment was given at this stage beyond the administration of ferri et ammon. cit., grs. 12 per diem. Ten days later blood examination showed: red cells, 4,928,000 per c.mm.; hæmoglobin, 70 per cent.; colour-index, 0·72; white cells, 12,400 (polymorph, 19 per cent.; lymphocytes, 72 per cent.; large mononuclear, 9 per cent.). Malarial parasites (*Plasmodium vivax*) were still present and showed rings, half and three-quarter grown schizonts, and gametocytes. Schüffner's dots were seen in the affected red cells. Three successive examinations of the male twin showed no blood abnormality or parasites. It appeared also to have no splenic enlargement. The mother's blood showed the following: red cells, 5,024,000 per c.mm.; Hb., 90 per cent.; C.I., 0·9; white cells, 5200 (polymorph, 66 per cent.; lymphocytes, 27 per cent.; large mononuclear, 7 per cent.). Parasites of benign tertian malaria were present. Wassermann, Kahn, and gonococcal fixation tests were negative.

Progress and treatment.—During the whole of the time the child has been under our observation there has been a complete absence of pyrexia or rigors. The child was treated with Atebrin, 0·05 gramme daily (in divided doses) for five days, followed by a further course of 0·05 g. daily for four days, after a six-day interval. There was some vomiting and slight diarrhœa during each course, but no other toxic symptoms or skin pigmentation. Films taken on four successive occasions have shown absence of malarial parasites in the blood. On April 23rd the count was as follows: red cells, 5,040,000 per c.mm.; Hb., 80 per cent.; C.I., 0·8; white cells, 8800 (polymorph

14 per cent.; lymphocytes, 80 per cent.; large mononuclear, 6 per cent.). The spleen also appears to be diminishing in size. The child appears well, and has steadily gained weight (12 lb. on May 10th shortly before discharge from hospital).

DISCUSSION

As this child was born in January, infection by mosquito bite seems to be almost impossible, especially as a mean temperature of 60° F. for at least 16 days must be maintained for *Plasmodium vivax* to develop in anopheles.[2]

In 1910 Beckel[3] recorded 12 cases of undoubted placental transmission of malaria. Griffiths and Mitchell[4] cite several cases described between 1893 and 1928. Thonnard-Neumann[5] reports a case where he found parasites of æstivo-autumnal malaria in the umbilical cord and in the peripheral blood at birth in the child of a syphilitic mother.

Clarke[6] found among 400 placentas that 4·7 per cent. were infected with malaria, but only found parasites in the umbilical cord in one case. Graham Henson[7] made frequent examinations after birth of children whose mothers had been treated for benign and malignant tertian and quartan malaria, but found no parasites in the blood, although they were detectable in the maternal blood just before and after labour. Thibault[8] examined 246 new-born infants whose mothers had active malaria, and found only three with malarial parasites in the blood.

The actual mode of transmission of congenital malaria has not been satisfactorily proved. Blacklock and Gordon[9] found that of pregnant women examined in Sierra Leone, 30 per cent. sustained placental infection, often leading to death of the fœtus in utero or of the child within a week of birth. They never found parasites in the umbilical cord or in the infant's blood, and considered death to be due to absorption of malarial toxins. Wislocki[10] made careful histological studies of the placenta and thought it unlikely that malarial organisms could penetrate the chorionic syncitium. In this instance it is interesting to record that Ascione and Marriotti[11] claimed to produce malarial infection in ten cases by injecting blood (5 cases) and cerebro-spinal fluid (5 cases) from malarial subjects, which had been passed through a Berkefeld V. and N. filter. Panagia[12] suggested that the merozoites might go through a "filterable phase" and then regenerate. If such be true, it is possible that they could pass the chorionic syncitium in such a phase. Zozaya and Sabogal[13] were, however, unable to confirm this mode of malarial inoculation. Such a mode of infection would also be disproved in our case, as only one of twins was affected.

The general opinion is that infection follows gross placental changes or placental trauma at birth. Concetti[14] believes that a placental infarct is the antecedent. Forbes[15] thought that some abnormality of gestation or delivery could be presumed as the parasite passes the placenta so rarely. It appears that malaria in the mother need not be active in order to give birth to an infected child (Beckel and Forbes).

CONCLUSIONS

In the case which we are reporting, where the first child of twins is non-infected and the second has malaria, it might be postulated that after the birth of the first child and the commencing separation of its placenta, the uterine contractions would have caused some separation of, and damage to, the fastening villi of the second placenta before the birth of the second child, and thus enabled parasites from the maternal blood sinuses to enter the child's circulation. We think that the absence of typical bouts of temperature and rigors may be explained by a transferred immunity from the mother during pregnancy.

SUMMARY

(1) A case of congenital malaria in one of twins is recorded. (2) Treatment with iron, without specific drugs, rapidly improved the anæmia. (3) Treatment with atebrin seems to have cured the malaria. (4) It appears that, in the absence of a known placental trauma or infarct, premature placental separation was the most probable cause of the transmission of the infection.

We wish to acknowledge our indebtedness to Sir Frederick Menzies, county medical officer, for permission to publish this case, and to Dr. P. Manson-Bahr for his help and advice.

THE EFFECT OF
SUDDEN SEVERE ANOXÆMIA ON THE FUNCTION OF THE HUMAN KIDNEY

BY R. A. MCCANCE, M.D., Ph.D. Camb.,
F.R.C.P. Lond.

ASSISTANT PHYSICIAN IN CHARGE OF BIOCHEMICAL RESEARCH
KING'S COLLEGE HOSPITAL, LONDON

IN human nephritis the excretion of urea, creatinine, and ammonia are usually simultaneously impaired. Following diabetic coma, however, as McCance and Lawrence[1] have shown, the kidney may temporarily become disorganised, so that the excretion of urea and creatinine may be practically in abeyance, while that of ammonia may remain quite normal. The present paper records another example of selective functional disorganisation.

The subject of these observations was a healthy male aged 36. For experimental purposes he had on four previous occasions overbreathed for 45 minutes, and did so for the fifth time on the day in question. Everything went according to plan until the subject had finished overbreathing. Then, either from carelessness or over-confidence, he did not voluntarily begin to breathe again as he had intended to do, and as he had always done before. Acute anoxæmia inevitably followed and was sufficiently severe to cause unconsciousness for about eight minutes. For the next two hours the subject was in a very collapsed state. He sweated profusely for a few minutes and began to feel very sick. He lay in an easy chair for about an hour and then, on attempting to get up, vomited much of the water which he had drunk

during the course of the experiment. Feeling a little better after this, he moved about the laboratory for a short time, went home by taxi, had a hot bath and got into bed. During all this time he felt intensely cold and miserable. Soon after getting into bed he began to feel better and after about 1½ hours to feel hungry. Accordingly he ate a substantial meal and went to sleep soon afterwards. On the following morning he was normal in every way.

Five specimens of urine were obtained and analysed, and the times at which they were obtained and their relation to the salient events are recorded in the Table. It is unfortunate that no record of the blood pressure was obtained, but the subject, who was himself in charge of the experiments and the only person present likely to realise its significance, omitted to have this measurement made. The oversight however does not in any way invalidate the reported observations. In the Table also will be found a record of the analytical results.

The methods used have been those described by McCance and Lawrence[1] except that (*a*) the urea in both blood and urine was determined by modifications of Beattie's method[2] which is a colorimetric xanthydrol procedure. (*b*) The ammonia was separated from the urine in Conway and Byrne's apparatus[3] and determined colorimetrically by Nessler's reagent. (*c*) The sulphates were determined by Fiske's[6] method.

It will be noticed that the volume of urine became very small during the period of collapse and that the percentage of urea in the urine fell to about one-third of its original figure. In consequence the urea clearance (van Slyke's formula) fell from 107 per cent. of normal, before overbreathing, to 17 per cent. of normal during the period of collapse. A fall in the urea clearance of this subject during overbreathing had been observed before, but on previous occasions the clearance rose again at once. That it did not do so on this occasion but fell still further seems to have been the direct result of the anoxæmia. The clearance remained subnormal for nearly 3 hours and then rose to 114 per cent. of normal. Since no determination except that of urea was made upon the blood, no other clearances can be discussed. It will be seen from the Table, however, how "rates" of excretion were affected. The rate of excretion of urea fell to about one-fifteenth of its original figure, while that of sulphate fell only to about two-thirds. The excretion of creatinine was still less affected. The rates of excretion of sodium, potassium, chlorine, and phosphorus fell to values between one-tenth and one-fifteenth of their initial figures. The relative rates of excretion of the ions was no doubt altered to some extent by the rapid changes of pH in the urine, but the general reduction is obvious. The fall in phosphorus may have no bearing on renal function after anoxæmia, since a fall has been observed to follow overbreathing on other occasions. Turning to the excretion of ammonia, all the evidence goes to show that this was not impaired by the anoxæmia. During the period of collapse the pH of the urine fell to 4·8 and the titratable acidity rose to ten times its previous value. The percentage of ammonia in the urine increased even more and the ratio NH_3/NH_3 plus titratable acidity actually rose a little after the anoxæmia. At this time also the "ammonia coefficient" rose to the remarkably high figure of 24. If, in fact, one assumes this ammonia to have been made from urea, the very great fall in the rate of urea excretion (and the urea clearance) is in part explained. Further, the changes of urinary pH show that the kidney had lost none of its capacity to concentrate hydrogen ions. This is true also of the kidney after diabetic coma.

The theoretical interpretation of all these observations is at present rather obscure because not enough is known of the way in which urea, creatinine, and sulphates are normally excreted; and particularly of how the clearances of these three substances are related to the true glomerular clearance. The observed falls in the excretion rates of creatinine, urea, sulphates, and possibly the other salt ions, coupled with the probability that some fall in blood pressure took place, indicates some fall in glomerular filtration. Since however one cannot assume that the change in the rate of excretion of either creatinine, sulphates, or urea is proportional to the change in the rate of glomerular filtration, especially under circumstances such as these, closer analysis becomes extremely difficult and would be of little value at this stage.

On the other hand, the excretion of ammonia is known to be a special function. The process is stated to be highly susceptible to poisoning by uranium.[4 5] The present results show that, apart from diabetic coma,[1] ammonia excretion may be left unaffected by agents which interfere with the excretion of many of the other urinary constituents.

SUMMARY

After overbreathing and accidental anoxæmia with unconsciousness it was found that: (1) The process of ammonia excretion and the ability to concentrate hydrogen ions were totally unaffected. (2) The rates of excretion of creatinine and of sulphates were reduced respectively to three-quarters and two-thirds of their initial values. (3) The rate of excretion of urea was reduced to one-fifteenth of its original value. Part of this reduction may have been due to the great increase in the excretion of ammonia. (4) The rates of excretion of water, sodium, potassium, chlorine, and phosphorus were reduced to between one-fifth and one-fifteenth of their original values. (5) Recovery was apparently complete in three hours.

The author is indebted to E. M. Widdowson, L. R. B. Shackleton, and R. J. Millar for assistance with some of the determinations.

Clinical and Laboratory Notes

ERYTHROMELALGIA AND PROCTALGIA FUGAX

BY H. S. CARTER, M.D. Leeds, D.P.H.
SENIOR ASSISTANT BACTERIOLOGIST, PUBLIC HEALTH DEPARTMENT, GLASGOW

THE paper on "proctalgia fugax" by Dr. Hess Thaysen in THE LANCET of August 3rd, 1935, reminds me of a patient I attended when I was in practice in 1920, whose symptoms were unusual and interesting. On notes of the case then taken I draw for this account.

Mrs. A., aged 52, complained of paroxysmal pain in the right foot with redness and swelling of the dorsum and toes. She had had five or six such attacks during a period of three years, the attacks lasting from three weeks to two months, during which times she had severe pain on many occasions lasting from a few minutes to about an hour. Between the periods of illness the foot gave no trouble; during the bouts, even when the pain was not active, the foot did not feel quite normal and, though not obviously swollen, felt "sort of numb and too big for my shoe." This condition of affairs, I was told, had variously been diagnosed as gout, erysipelas, and inflammation of the foot. Being at that time in the throes of the composition of a thesis on causalgia, I had a mind above common diseases, and boldly diagnosed erythromelalgia, which in the light of a little more wisdom I think was correct.

The earlier attacks had consisted solely of pain in the toes and anterior part of the sole of the foot, and the redness and swelling had supervened in later attacks. Heat aggravated the condition, and she had been worse in South Africa whence she had come, than since she had been in our cooler climate. She could not bear to be near a fire during the attacks, most of which, though not all, had occurred in hot weather. The pain was an intense burning pain accompanied by sensations of throbbing, and worse when the leg was dependent. She got most comfort by lying down, elevating the leg on a pillow, and covering the foot with cloths soaked in cold water. The redness during a paroxysm, as I saw it, was quite bright and affected chiefly the great toe and little toe and the outer side of the foot. There was nothing above the ankle. As an attack subsided and the pain diminished, the skin of the foot was hyperæsthetic, stroking or gently scratching giving rise to unpleasant paræsthesiæ, and the colour of the skin became a curious pale mauve or heliotrope. No hyperidrosis, thinning of the skin, delayed desquamation, deformity of the nails or other trophic change was observed. During an attack the foot felt hot, the vessels were distended, and there was distinct swelling without pitting.

It was in the course of the treatment of this disability during an exacerbation lasting about six weeks that the disconcerting symptom of rectal pain appeared. She had four attacks of this, three in the daytime and one at night at intervals of several days. The duration was short, and on the two occasions I was sent for the pain had subsided by the time I arrived. Her description of it was graphic enough. She experienced a slowly increasing sense of fullness about four inches up in the rectum, as though there was "a small ball expanding slowly." This sensation of expansion or tension soon turned to pain which increased to an intense ache in a few minutes and which at its zenith became almost unbearable, and caused profuse local sweating of the nates sufficient to leave a damp area on the clothing nearest the skin. This pain never lasted more than five minutes at most and subsided fairly quickly, leaving a feeling of weakness and comparative exhaustion. No associated sensations in the præcordium or epigastrium as described by Dr. Thaysen were complained of, though the exhaustion after the attack amounted to a feeling of faintness. There was no accompanying feeling of tenesmus or passage of flatus. The whole attack was over well inside fifteen minutes. This rectal pain never occurred simultaneously with a paroxysm in the foot.

The patient was a woman of average build in good general health who had just passed through an easy climacteric. She had had one child with easy labour and no pelvic complications or sequelæ. There was no history of intestinal illness such as dysentery. A rectal examination revealed nothing. There were no hæmorrhoids and no trouble with defæcation or micturition. The urine was normal, the blood pressure 148/95 mm. Examination of the heart, lungs, and abdomen yielded no help, and there were no signs in the nervous system suggesting syringomyelia or disseminated sclerosis or tabes. The fundi appeared normal. Unfortunately the Wassermann tests on the blood and cerebro-spinal fluid were not carried out, but there was no history or evidence of earlier syphilis. In short, nothing was found to account for the distressing symptoms, which I did not understand.

The attacks of rectal pain were four only and did not recur at that time, and the erythromelalgia becoming quiescent I ceased to see the patient and have no further history. The whole condition was treated with belladonna, valerian, and bromide, with aspirin during the attacks of pain in the foot, together with applications of menthol and cold to the foot. No special treatment was directed at the rectal pain for which no specific cause was found and of which the evanescence probably impressed me more than its severity which I never witnessed. I have thought since that it might have been one of those painful spasms of tubular structures which are far from uncommon in neuropathic individuals.

The coexistence of the conditions erythromelalgia and proctalgia is interesting and rare and suggests a common origin. I have since seen a second case of erythromelalgia in a war pensioner, but he had no rectal pain. The ætiology of "red neuralgia" is obscure but it has been suggested that it may originate in an affection of the vasomotor centres in the cord.

Possibly some minute disturbance in the region of the lower lumbosacral roots may account for these phenomena. The equally intense and similar pain of causalgia (thermalgia) may be caused by a microscopic non-progressive lesion of a peripheral nerve. A similar lesion in another place may account for erythromelalgia and proctalgia, contemplation of which provides an interesting speculative study in neurological localisation.

A CASE OF PSITTACOSIS

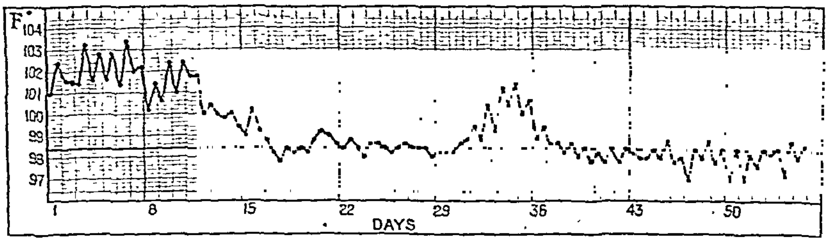
By Smeeton Johnson, M.D. Lond.

HON. PHYSICIAN TO THE GENERAL HOSPITAL, KIDDERMINSTER

With a note by

Walter Levinthal, M.D. Munich

Psittacosis or parrot disease became widespread in Western Europe in 1929–30, and the importation of parrots and parakeets has been prohibited in certain countries. It has been suggested that the budgerigar, which is less susceptible to psittacosis than the parrot, may become a carrier of the disease,[1] and this suggestion lends interest to the following case.



Temperature chart from May 15th.

The patient is a man aged 63. He has a study in his garden connected to his house by a covered glass passage, which for the last eighteen months has been used as an aviary for 10–14 budgerigars. Consequently he has walked through the aviary several times daily. No particular illness has been noticed amongst the birds, but two or three have mysteriously died. These were purchased from two independent dealers earlier in the year.

On May 15th, 1935, the patient was seen for the first time. He gave a history of headache, pains in the back and limbs, and general malaise of twenty-four hours' duration. He was emotional and evidently felt very ill. His temperature was 101° F., pulse-rate 90, respirations 20, and his tongue was moist and coated at the back. There were no other signs of disease. On the third day of the illness an area of dullness was discovered below the angle of the right scapula. Breath sounds were diminished and heard with difficulty in this region, but there was no cough or expectoration and no pain. The temperature was maintained at 101–3°, with pulse-rate 90 and respirations 24. There was profuse sweating at night and constipation. The patient had intense headache of a throbbing character, stuffiness of the nose, and occasional slight epistaxis. He was apathetic and took little notice of his surroundings, but roused up when spoken to. At the end of the first week the symptoms were much about the same, but he was more apathetic and drowsy. The patch of dullness in the right chest was still present, and there was almost complete absence of breath sounds in this region. There was no abdominal distension or enlargement of the spleen, and there was no rash.

The Widal reaction on the ninth day of the illness was negative to typhoid, paratyphoid A and B, and *Bacillus melitensis.* Bacteriological examination of the fæces was also negative. On May 24th a specimen of sputum was sent to Dr. Walter Levinthal, at the National Institute for Medical Research, Hampstead. As a result of his tests, which are described later, he was able to demonstrate the presence of the psittacosis virus.

On May 30th crepitant râles were heard in the right chest in the scapular region, and cough and expectoration became more frequent, but were never profuse. The temperature reached the normal line and the patient felt very much better. Convalescence continued, and on June 11th, all symptoms having disappeared, the patient was allowed to get up.

A specimen of blood was sent to Prof. S. P. Bedson at the London Hospital on June 13th. Prof. Bedson later reported that the serum gave a positive reaction with the complement-fixation test for psittacosis.

On June 14th the patient complained of pain in the right scapular region. Examination revealed an area of dullness corresponding with the original patch of dullness, and there was absence of breath sounds. There was occasional cough which was painful, and expectoration of mucus streaked with a little dark blood. The temperature was 100°, with pulse-rate 90 and respirations 24. The temperature continued to rise for three days and then gradually fell to normal on the seventh day. On the fourth day the pain had practically gone, and on the sixth day breath sounds began to return, accompanied by fine crepitant râles. There was no severe headache, and perspiration was not excessive.

This case at first resembled a typhoid septicæmia. Certain features, however, distinguished it from the typhoid group of diseases. The onset was sudden and the temperature rapidly rose to its maximum. Headache was intense and perspiration profuse, necessitating the changing of the night attire two or three times a night. Constipation was the rule throughout the illness, and there were no other abdominal symptoms. The spleen was never palpable and there was no rash. During the height of the fever the patient was apathetic and drowsy, and on one or two occasions only was there a little muttering delirium.

The lung symptoms were certainly unusual. The toneless dullness, with very faint or absent breath sounds and normal or slightly increased vocal resonance, and the absence of pain, cough, and expectoration, gave a picture very different from that of lobar pneumonia. Evidently there was some consolidation of the lung, probably associated with obstruction of the smaller bronchi. Resolution was accompanied by fine râles. The fever was maintained for two weeks and subsided to normal during the third week. Throughout the illness the pulse-rate was between 80 and 90, and the respirations were never more than 24. The rise in temperature on June 14th and the return of the lung symptoms were evidence of a mild relapse.

Experimental demonstration of the virus of psittacosis in the sputum by Dr. Levinthal, and the positive reaction of the complement-fixation test obtained by Prof. Bedson, add greatly to the interest of the case.

Addendum by Dr. Levinthal

On May 25th Dr. Johnson sent me a small amount of sputum, stating in a letter that, judging the case from the clinical aspect, he was convinced that it was one of psittacosis. I was able to confirm his clinical diagnosis by the experimental demonstration of the virus.

---

[1] See The Lancet, 1935, i., 1207 and 1226.

The sputum, which contained much more mucus and saliva than pus, was emulsified in the tenfold amount of broth by thoroughly shaking with glass beads in a wide-mouth stoppered bottle. The unfiltered material killed one mouse injected intraperitoneally in two days with a pneumococcus of the group IV. The sputum emulsion was filtered through a rather tight sand and paper pulp filter. In view of the fact that the filtrate was nearly clear, it was not filtered further, and was injected intraperitoneally into two mice, one of which was reinoculated with the same amount (1·0 c.cm.) on the two following days. The mice died on the eighth and ninth days with a condition which is characteristic of the infection with a medium amount of virus (cf. THE LANCET, 1935, i., 1209). The virus was abundantly present in the masses of fibrin found in the abdominal cavity, in the perihepatitic and perisplenitic membranes, in the cells of the pericardial serofibrinous exudate, and somewhat less in the spleen. The virulence test, performed with the second subculture in a chicken-embryo medium, revealed the high virulence of the strain with a positive result up to the last titrated dilution of $0·5 \times 10^{-9}$ (dead on the 14th day).

It may be added that a budgerigar, which was found dead in the patient's house on June 3rd, had no signs of psittacosis and gave no positive result in the mouse test. On the other hand, the psittacosis virus was detected in one of four budgerigars purchased at random in the middle of June from a bird shop which supplied the patient's aviary.

FRACTURE OF THE RIBS IN WHOOPING-COUGH

BY W. EDGECOMBE, M.D., F.R.C.P. Lond., F.R.C.S. Eng.

HON. PHYSICIAN TO THE HARROGATE AND DISTRICT GENERAL HOSPITAL

FRACTURE of the ribs during a paroxysm of whooping-cough is rare enough to deserve record.

Miss A., aged 18, a well-developed, apparently healthy normal girl, of the non-athletic type, began with a cough on May 24th, 1935. At the end of a week it became clear she was suffering from whooping-cough. On June 7th, during a paroxysm of coughing, she complained of acute pain over the left lower ribs posteriorly. On examination nothing definite was discovered, and the pain was thought to be due to muscular strain. A tight bandage to restrain the movement of the chest wall eased the pain considerably. A week later, on June 13th, during a violent fit of coughing, she felt a severe pain over the lower ribs behind on the right side, and said that she definitely heard a crack as though a bone had broken. On examination there was an area of acute tenderness over the eleventh rib on the right side, and crepitus could be felt on palpation and heard through the stethoscope.

The ribs were tightly bound with strapping which gave considerable relief to the pain. The following day an X ray photograph was taken which disclosed a fracture of the eleventh rib on the *left* side at the junction of the distal and middle third, accounting for the first attack of pain, and a fracture of the eleventh rib at a similar site on the *right* side corresponding to the second attack of pain. Firm strapping made the pain tolerable and the attack of whooping-cough, which was moderately though not excessively severe, ran a normal course of about seven weeks.

Inquiry into her previous history disclosed the fact that during birth she sustained a fracture of the thigh. Labour was prolonged and delivery difficult. At the age of 14 she had a fracture of the right forearm due to a fall in the gymnasium at school. She played the ordinary school games, though not strenuously, and encountered, presumably, the usual rough and tumble knocks without mishap. She has had no illness of any moment.

It was thought desirable to radiograph the bones of the extremities for evidence of deficient calcification. This was done by Dr. C. Hitchcock of Harrogate. The radiograms of the hands compared with those of a normal control of the same age show definitely less density in the bone shadows. The radius and ulna, the tarsal bones, and the tibia and fibula showed similar evidence of deficient calcification. In the epiphyseal ends of the radius at the wrist and to a less extent in the carpal bones and in the lower end of the tibia minute sharply defined points of dense sclerosis about 1 mm. in diameter can be seen. This condition is mentioned by some observers as being associated with fragility of the bones.

The patient has been put on a course of calcium and vitamin D, and it is intended to radiograph the bones again in six months' time.

REVIEWS AND NOTICES OF BOOKS

Diseases of Children

A Work for the Practising Physician. By Dr. M. PFAUNDLER, Professor of Children's Diseases and Director of the Children's Clinic at the University of Munich; and Dr. A. SCHLOSSMANN, Professor of Children's Diseases and Director of the Children's Clinic at the Medical Academy in Düsseldorf. English translation: American Editor-in-Chief, M. G. PETERMAN, Sc.B., A.M., M.D., Professor and Director, Department of Pediatrics, Marquette University Medical School. London: J. B. Lippincott Co. 1935. In five volumes. Pp. 544, 512, 689, 575, and 545. 9 gns. (5 vols.).

THE appearance of a new edition in English of Pfaundler and Schlossmann's standard system of pædiatrics is an event of first importance. Based on the fourth German edition, which appeared just before the death of Dr. Schlossmann, the present English translation has been carried out by 21 American pædiatricians, who have in some places added notes to the original work. This latter is itself widely representative, having been written by over sixty authorities, for the most part German, but including contributors from Austria, Holland, Finland, and America. A valuable feature is the section devoted to tropical diseases in childhood, written by Dr. Wyckerheld Bisdom of Java.

It would be difficult to over-estimate the influence that this work has had on physicians all over the world since the appearance of the first German edition in 1906. It was then largely the work of youthful pædiatricians, but set a standard of scholarship of which the most mature might be proud. With the passage of years, a number of contributors have resigned their association with the work, and others have taken their place; many of the original team, however, including both editors, took part in the production of the fourth edition, and the combination of freshness and maturity is a happy one. In the translation the original has been faithfully rendered into clear, if not always scholarly, English. Unfortunately, however, a few sections fall so far short of the general standard that they seriously mar the work as a whole; for example, that concerned with diseases of the organs of locomotion is in places almost unintelligible. "Here we deal with phenomena concerning more anatomical than clinical interests" it begins brightly, and continues a shade more solemnly "the heart muscle bellies protrude from the body surface like irregular spindle-shaped tumors. After a duration of many years exitus threatens from an intercurrent infection."

The work is divided into 5 volumes. Vol. I. opens with a history of pædiatrics by Prof. Brüning, which is followed by sections of a more general nature (biology, pathology, and morbidity of early life, examination of sick children, general prophylaxis, child welfare, and therapy), a consideration of nutrition and growth, and a discussion on the special pathology of different age-periods. In Vol. II. deficiency diseases and diseases of the blood, circulatory system, and endocrine glands are included; Vol. III. is devoted to infectious diseases and rheumatism; and Vol. IV. to diseases of the digestive and respiratory systems. Vol. V. comprises the diseases of the genito-urinary and nervous system, and of the motor apparatus, and includes an excellent index. This arrangement necessitates a certain amount of overlapping, but in a work of this nature this is an advantage, since the views of more than one authority are obtainable on different aspects of the same subject. The general production of the volumes is admirable. A heavy surfaced paper has been used, which has made possible the reproduction of radiograms in the text, and the numerous illustrations are well chosen and clear. The selective use of small type has kept the size of the volumes within reasonable limits. As a work of reference there is one great disadvantage to this system of pædiatrics: no exact references to the literature are given, although authors are quoted by name. In spite of this we commend the book as one of the most important and complete systems of pædiatrics obtainable.

Endoscopie et pleurolyse

By O. M. Mistal, médecin directeur de l'établissement Clovelly, Montana. Paris: Masson et Cie. 1935. Pp. 436. Fr.55

Beginning with an anatomical and histological description of adhesions, the author goes on to describe early attempts at their division by open operation. The following chapter on indications and contraindications of thoracoscopy should be one of the most important in the book if the author had not such an unfortunate craving for completeness that the reader can hardly see the wood for trees. Among the rarer indications for thoracoscopy he gives the confirmation of healing before letting out a pneumothorax; also the observation of the effect of drugs and rays on certain diseases of the lungs and pleura. The thoracoscopic appearances of two forms of syphilis of the pleura are described. The next chapter deals with the instruments used in thoracoscopy; this section contains 80 illustrations, and it is unlikely that any instrument of importance has been omitted. After a description of the anatomy of the pleural cavity, there follow details of the technique of the division of adhesions by cautery, by diathermy, and by a combination of the two. In considering the results of the operation, the writer finds that out of 65 thoracoscopic examinations, adhesions could be divided in 52 cases: 34 patients were improved, 13 stationary, and 5 worse. Perforation of the lung occurred in 3 cases (only 1 during the operation) and hæmorrhage also three times. Serious effusions were noted in 8 cases, slight ones in 34, only 7 cases escaping entirely.

Dr. Mistal describes a new application of thoracoscopy of his own invention. By means of a specially constructed quartz electrode, introduced through a sinus, the pleura may be irradiated with ultra-violet light. In a concluding paragraph he states that "the direct irradiation of the pleural cavity with ultra-violet rays, the introduction of various gases and drugs and of radium, following our own method, will probably have great therapeutic importance in the treatment of certain pulmonary affections." Perhaps they will; but one cannot help feeling that angels would fear to tread some of the paths Dr. Mistal traverses without a backward glance.

Heart Disease in the Tropics

By H. O. Gunewardene, M.B., B.S.Lond., D.M.R.E. Camb., late Clinical Assistant, National Heart Hospital, London; Consulting Cardiologist, Columbo, Ceylon. India: Butterworth and Co., Ltd. 1935. Pp. 101. 8s. 6*d*.

This book should interest others besides those whose work is in the tropics. Dr. Gunewardene believes that new lines of investigation may suggest themselves to those interested in heart disease from reading a description of, for example, such a condition as rheumatic heart disease as it manifests itself in an entirely different climate and setting. One of the most interesting chapters deals with cardiac disability as a result of ankylostoma infection which, according to the author, is comparable with rheumatic fever as a common cause of heart disease in the tropics. While studying this condition he was greatly impressed by the variety of murmurs which might develop during the course of the disease, and he was able to convince himself and others that not only systolic but also diastolic and presystolic murmurs might be heard, disappearing as the patient recovered. To illustrate these observations a full account of several cases is given. Apart from this a review is given of cardiovascular phenomena in tropical climates, and sections on rheumatic heart disease, diabetes, diphtheria, syphilis, and high blood pressure. The value of digitalis, oxygen, and potassium iodide is briefly discussed, and a short section on the effect of altitude on cardiovascular cases is included.

Inhalation Therapy Technique

By W. E. Collison. With Foreword by Sir Bruce Bruce-Porter, K.B.E., C.M.G. London: William Heinemann Ltd. 1935. Pp. 76. 5*s*.

Although beginning with a historical introduction describing early types of atomiser, this book is really an advertisement for the author's Apneu inhaler. This fact does not detract either from the well-known merits of the instrument described, or from the value of the information given. Major Collison's inhaler is mounted on an oxygen cylinder from which the gas can be made to pass through medicated solutions; the high pressure of the oxygen jet results in vaporisation into smaller particles than can be obtained by atomisers working with low pressures. The oxygen with its content of drugs in fine suspension is administered to the patient by means of a rubber bag and face mask, similar to those used for nitrous oxide anæsthesia. The apparatus is simple to use as it only requires a turn of the handle to give one or other of the atomised drugs or a mixture of the two. With another setting pure oxygen can be given.

After a clear description of the apparatus the writer proceeds to give some recommendations for its use in various affections of the respiratory tract. The preparations advised are given under such trade names as *apneugene and campheugene*, but the composition of each is given. Asthma, bronchitis and emphysema, bronchiectasis, pulmonary tuberculosis, laryngitis, and even the common cold has its appropriate inhalation. The last part of the book consists in extracts from articles in medical publications in which the apneu method has received favourable mention.

The medical profession has, undoubtedly, been backward in inhalation therapy, and even the ridiculously inefficient administration of oxygen through a glass funnel has not been altogether given up; in Major Collison's book readers will find useful information about an efficient method of inhalation.

What of the Child?

By Andrew Kefalas, M.A., M.B., Ch.B. London: William Heinemann Ltd. Pp. 187. 5s.

In the flood of books on children this little volume takes a useful place. The author describes the psychophysics of development and peculiar habits. He discusses the rôle of the parents in upbringing, in discipline, and in punishment. He describes the play activities of children, their daydreams, their fears and peculiarities of character. He also gives special attention to the important problem of puberty and adolescence, and the various social and personal anomalies which colour youthful development. He also has some sensible advice to give on sex instruction. The book as a whole is intelligent and sympathetic, and can be recommended not only to parents but to general practitioners who are awakening to the psychological aspects of child development.

Introduction to Pharmacology and Therapeutics

Fourth edition. By J. A. Gunn, M.A., M.D., D.Sc., F.R.C.P., Professor of Pharmacology in the University of Oxford and Fellow of Balliol College. London: Humphrey Milford, Oxford University Press. Pp. 237. 5s.

The fact that this handbook has reached its fourth edition within five years is a clear indication that there can be few students and teachers of medicine who are not aware of Prof. Gunn's valuable work. The book is intended to be read before the student attends lectures on pharmacology; but it provides such a comprehensive survey of the whole subject that it might well be read by anyone desiring to refresh his memory as to the principles underlying the art of healing. The new edition shows few changes, for little more than a year has elapsed since the third edition was published, and it can be warmly recommended as a sane, critical, and attractive account of the subject.

Electrocardiography

By Chauncey C. Maher, B.S., M.D., Assistant Professor of Medicine, North-Western University and the Montgomery Ward Medical Clinics. London: Baillière, Tindall and Cox. Pp. 250. 18s.

Dr. Maher's book has been written not for the cardiologist but for practitioners and for those who specialise in departments of medicine other than cardiology. Its aim is to enable them to correlate the electrocardiographic with the clinical findings. The two opening chapters deal with the clinical classification of heart disease and the arrhythmias, while in a short third chapter the author outlines the anatomy of the conducting system. Chapters 4 and 5 are devoted to technique and to a consideration of the features of normal records. From here onwards the author follows a uniform scheme. Each disorder of the heart's mechanism is illustrated first, by a drawing of the Purkinjé system to indicate the site of the lesion, secondly, by a diagrammatic electrocardiogram, and thirdly, by actual records. To each record is appended a tabulated analysis, the first part of which deals with the clinical and the second with the electrocardiographic diagnosis. This method makes it easy for the novice to interpret the records, but provides somewhat tedious reading for those readers who have some previous knowledge of the subject.

The chapter which appealed to us most was that dealing with axis deviation. This subject is illustrated by some excellent radiograms which enable the reader to compare the anatomical with the electrical axis of the heart in cases where the brunt of the lesion falls on the right and left ventricle respectively. It also illustrates well the range of normal variation in the electrical deviation associated with differences in the lie of the heart. The records are well chosen and clearly reproduced.

Encyclopedia of Veterinary Medicine, Surgery and Obstetrics

Second edition. By George H. Wooldridge, F.R.C.V.S., M.R.I.A., F.R. San. I. Professor of Medicine and Hygiene, Royal Veterinary College, London; Hon. Consulting Veterinary Surgeon to the Zoological Society, London. London: Humphrey Milford, Oxford University Press. In two vols. Pp. 1652. 6 gns.

This encyclopædia has been brought up to date, and some chapters, including those on actinomycosis, actinobacillosis, milk fever and braxy, have been rewritten. New chapters are supplied on lamb dysentery, swine influenza, spinal anæsthesia, surgical narcosis with avertin and nembutal, gland grafting, infection and immunity, and a veterinary pharmacopœia has been added. As regards arrangement, the first volume of 836 pages contains a section dealing with diseases caused by bacteria or filtrable viruses, the conditions being grouped according to the animal species; this system is not, however, adhered to, since the chapter in which contagious mastitis is discussed is to be found amongst surgical conditions. There follow sections which discuss protozoal, constitutional and local diseases. The second volume of 816 pages deals with surgery and obstetrics. Most of the chapters have been written by Prof. Wooldridge, but 48 other workers have contributed articles on subjects with which they are particularly familiar. Chapters on horse sickness, contagious bovine pleuropneumonia, bluetongue, swine fever, piroplasmosis, acariasis and mastitis deserve special mention; whilst the veterinary pharmacopœia and the chapter on infection and immunity are useful adjuncts to the new edition. Some aspects of veterinary medicine have received inadequate treatment: thus the whole subject of plant poisons is dealt with in only six pages, whilst with two or three exceptions all diseases of poultry are omitted.

In collecting and assembling a mass of scattered and unavailable information, Prof. Wooldridge has done a great service to the cause of animal health; and if this encyclopædia is amplified in certain places in future editions, the veterinary professor will find it almost indispensable.

THE LANCET

LONDON: SATURDAY, AUGUST 17, 1935

SPECIFIC CONTROL OF WHOOPING-COUGH

Like measles, whooping-cough is not generally notifiable, and our idea of its incidence must be based largely on estimates such as those of Stocks and Karn, quoted by Drs. Paterson, Bailey, and Waller in the paper which appears in our present issue. Our knowledge of the morbidity due to its complications is even less exact. The mortality, owing to the enduring nature of the illness, is probably understated to a lesser degree than that of measles, in which the deaths tend to be ascribed to the complications to the exclusion of the primary infection; indeed, the figures given by Dr. Stocks in his paper on p. 386 suggest that whooping-cough is sometimes blamed for deaths which are chiefly the result of influenza epidemics. But the fact remains that, though the public still looks on it lightly, this disease is now the most formidable of the acute specific infections of childhood.

The therapy is notoriously unsatisfactory. The new drugs proposed are legion. Vaunted for a time they are finally rejected in favour of the few well-tried but not always reliable sedatives prescribed by our predecessors. Although success for vaccine therapy has been claimed by some, most observers report results which are at best equivocal. Serum treatment is little more promising: Dr. Paterson and his collaborators note that Jundell seems to have secured some amelioration of the attack by means of the injection of reactivated adult-immune serum, but they themselves are unable to record any apparent improvement from the treatment of a series of cases with convalescent serum. Specific prophylaxis on the other hand arouses greater hope. The work of Madsen in Denmark and of Sauer in the United States of America is particularly well known, and opinion, if not unanimous, is much less divided over the value of vaccines in prophylaxis, provided they are prepared from fresh strains in the correct antigenic phase and injected in adequate doses at a sufficient interval before exposure. In recording the results of prophylactic injection of convalescent serum Paterson, Bailey, and Waller are rightly cautious in expressing an opinion about its value. Their series of 95 contacts with 55 controls is too small to have statistical significance, but the fact that 42 per cent. of the presumably infected contacts did not develop the disease, in comparison with only 11 per cent. of the controls, is a basis at least for further investigation, and this no doubt will be made.

In an attempt to determine whether a child had had an infection with the Bordet-Gengou bacillus on some previous occasion or whether vaccine prophylaxis in a non-infected child had been of any avail, Dr. Paterson and his co-workers have made use of a skin-test in four groups of children. An area of hyperæmia, about three-quarters of an inch across, appearing 24–48 hours after the intradermal injection of a minimal amount of vaccine was considered as positive and an indication of an allergic state following natural infection with, or vaccine prophylaxis against, the Bordet-Gengou bacillus. The utility of such a test, if its reliability can be confirmed, is obvious. The results recorded are peculiarly interesting, inasmuch as Siebler and Okrent[1] employing a similar test considered that hyperæmia indicated susceptibility and a negative reading immunity following vaccine prophylaxis—an interpretation exactly opposite to that of the present observers.

INDUSTRIAL MEDICINE IN FLUX

The organisation of industry is undergoing changes and developments that are both rapid and fundamental. In the course of comparatively few years it has had to cope with war, boom, depression, and a constant flow of new inventions. It is in a state of flux and he would be rash who would attempt to forecast the form of the next phase of stability. In the midst of this vital but restless period the study and practice of industrial hygiene and medicine have progressed if not in a spectacular yet in a very encouraging way. It has been impossible for the medical needs of industry to reach the stage of clear definition while industry itself is undergoing a phase of extensive internal change, but in spite of the fact that industrial medicine is still adolescent great strides have been taken. A stage has been reached where, given intelligent coöperation, the medical hazards of occupation can be countered and work made reasonably safe and congenial. It is useless to deny that this state of affairs is made easier of attainment where the unit of production is large, and whatever drawbacks there may be to so-called rationalisation ease and efficiency of medical supervision is not one of them. Centralised control of production is a powerful ally of industrial medicine. How far this tendency will spread is uncertain; meanwhile the vast majority of industrial concerns employ less than a hundred workers, and the problem of the medical supervision of these remains. A medical scheme does not work economically in units of less than a thousand workers and the alternative method of groups of small factories coöperating for medical services has unfortunately received practically *no trial*. It is something well worthy of experiment.

Many matters which call for medical supervision at work are not receiving, or are not capable of receiving, attention in any other way. These range from the proper selection of staff and the prevention and treatment of hazards and accidents to the equally important coöperation with private doctors over such things as return to work combined with treatment, and consultation over individual traits and circumstances that only become manifest in the patient's working environment. Our columns in the past few years have contained numerous contributions dealing with these matters, and future developments were considered at the recent congress of the Royal Sanitary Institute in Bournemouth, when a section of hygiene in industry collaborated with the Industrial Welfare Society. At this congress Dr. T. E. A. STOWELL emphasised the foundations common to all medical services in industry; no matter what the needs of a special concern might be there is an A.B.C. of industrial hygiene without which nothing can succeed. Dr. W. D. JENKINS outlined the opportunities and duties that exist for employers to help and care for their older workmen. Important now this is a side that will gain in importance if the average age of the population continues to rise and the proportion of older people to increase. Even after they have left industry these older people can be useful citizens and it is a social duty to see that in their later years their work does not unnecessarily impair their powers of happy and useful life. The distribution of goods is undergoing rapid changes and not the least of these is that more people are being employed in what may be called the ancillary services of production. Though not strictly industrial the work of the sales-shop and store is organised on lines which call for medical supervision difficult to apply except in large single establishments. Dr. M. L. DOBBIE-BATEMAN dealt with the shop assistant and the meeting was notable for the emphasis laid on the medical problems of retail selling. Working with a large retail staff, albeit under the ideal condition of having them almost under one roof, Dr. DOBBIE-BATEMAN has utilised her opportunities to collect information about an occupation which in general is scattered in small units but which nevertheless calls for as much medical attention as the ordinary run of factory work. Lord TRENT, who presided over the section, was able to draw on his own administrative experience and stated frankly that the picture of the life of a shop-assistant in big cities can be an unpleasant one unless the employer is expertly advised and takes medical considerations into account in a fair and sympathetic manner.

The boundaries of occupational medicine are thus widening from mines and factories to offices and shops—from mere hazards to the deeper, more intimate and individual psychological maladjustments of the worker. That this extension could under improper administration result in victimisation is obvious, but the phase of suspicion is dying down as industrial medical officers continue to prove that they are doctors to their patients before they are servants to anyone, and they are gradually widening their own function to embrace those wider economic interests which are so potent in the making or breaking of the health of individual workers. Lord TRENT showed a deep understanding of this social aspect of medicine when he stated that "the removal of that perpetual fear of losing one's job which besets working people of all ages [is] the greatest human problem that will have to be solved in the course of this century." The acknowledgment that economics and medicine are inextricably interwoven is at once the justification for industrial medicine and its greatest urge to progressive and far-seeing development. The medical profession as a whole has a deep concern in the trends of industrial and economic organisation because while a movement, such as for instance large-scale grouping, may bring forward new problems it also produces new opportunities; and who will deny that in a complex world centralisation is essential if we would remain sane and that through coöperative effort preventive medicine is made easier and treatment more comprehensive and efficient? Industrial medicine will develop not with the object of increasing sectional profits but because an industrial state cannot afford to leave untilled a most fruitful and economically efficient field of preventive and curative medicine.

TRAINING THE SQUINTING EYE

THE interest now taken in the treatment of squint, whether with or without operation, shows no signs of abating. Miss DOBSON's most recent contribution to the subject[1] will be found of great practical use. She describes a device for the use of children whose concomitant squint has already been overcome, or nearly so, either by the wearing of glasses or by other methods, but in whom one eye remains to a greater or less extent amblyopic from disuse. Suppression of the image in a squinting eye is the great obstacle to successful orthoptic treatment. Hitherto complete occlusion of the non-squinting eye has been the favourite method for developing vision in a squinting one, and in the case of young children with constant monolateral squint it is often the only practicable one. The ideal method of occlusion, which admits of some indirect vision on the temporal side of the field but completely shuts off direct vision, was set out in our columns (July 27th, p. 183) by Mrs. THORNETT-JOHNSON, but she admits that for any child after the age of six with vision in the squinting eye reduced to much below 6/60 it is a very trying and long treatment. For older children, although it may be possible, unless the vision of the squinting eye has improved considerably beyond 6/60 it must necessarily be a serious handicap to education. In Mrs. THORNETT-JOHNSON's experience the average time taken at a clinic to restore the vision of a squinting eye seeing less than 6/60 to normal has been 18 months, the shortest being 6 months and the longest 3 years. Any method of quickening the pace would be welcome. When the child is able to read, when the squint is only slight or occasional, and when the vision of the squinting eye is good enough, with refraction corrected, to read large print by itself, it is easier to overcome the remaining amblyopia by employing it in harness with the good eye; and in this way there is then not only the urge to interpret the image that falls upon the retina of the squinting eye but also the stimulus of binocular vision.

---

[1] The Amblyopia Reader: A System of Eye-sight Development. With foreword and notes by Margaret Dobson, M.D. London: Rembrandt Photogravure Ltd. Pp. 93. 15s.

Many varieties of apparatus are in vogue to effect this object. One of the most successful is the cheiroscope (or eye awakener) of Maddox. Various forms of "amblyoscope" and "kinetic stereoscope" and the complicated (and necessarily expensive) "synoptophore" are in use for this purpose. There is room for a simpler and less expensive method of effecting the required object and one which may be used at home. Miss Dobson's method is ingenious. She has had a number of nursery rhymes and simple stories printed with certain words and pictures half in black and half in orange. The vision of the two eyes of the child having been made approximately equal, if necessary by means of a Chavasse glass before the good eye, a ruby red shield is also placed before that eye so that the halves of the words or pictures printed in orange are completely obliterated, but so that the amblyopic eye with its refraction corrected can see the whole of each word, the size of the print being graded according to the degree of the amblyopia. In this way the help of the good eye is called in to assist in the development of the sight of the bad one. The idea is a good one and will, we anticipate, be extensively used. Anyone proposing to undertake the non-operative treatment of squint in children would do well to inspect the methods in use at existing clinics before purchasing expensive apparatus. Apart from apparatus a large amount of both patience and tact are required for success.

CLEARING THE TUBES IN ASTHMA

In a large proportion of patients with asthma the respiratory tract is unhealthy. The nasal mucosa is swollen, the ostia of the sinuses are blocked, and bacteria flourish in the stagnant secretions. There is a persistent low-grade bronchitis and the mucous plugs expectorated from the smallest bronchioles contain leucocytes and bacteria; the latter often in almost pure culture. Acute episodes such as sinusitis, hæmoptysis, pleurisy, and pneumonia are abnormally common. The pulmonary lesions, like those in the nose, must often be secondary to hypersecretion of mucus and œdema of the epithelium, which block the small bronchioles and favour stagnation and infection. Exceptionally, the secretion of mucus may be so great as to obstruct the whole bronchial tree and cause death from asphyxia, as in a case reported by Brulé and others.[1] A less uncommon accident is massive collapse from obstruction of a single main bronchus. In theory, the unhealthy state of the respiratory tract may be regarded as a result of asthma, but in practice it is known to be an important factor in the perpetuation of the disease. Methods to restore a healthier state of the respiratory system are therefore an important part in the treatment of asthma, and in this country the Asthma Research Council has emphasised the value of respiratory exercises which empty the bronchi and deflate the lungs. Shambaugh and Alter[2] in America report good results in fifty cases of bronchial asthma from a regimen based on elimination by postural drainage of the accompanying bronchial and pulmonary exudate. The patient kneels on a chair or stool with his hands on the floor, and coughs as nearly continuously as possible, until the bronchi have been completely emptied. The treatment is carried out twice a day, for a minimum of three minutes, and any coughing between is regarded as a sign that insufficient evacuation has been accomplished. A simple saline mixture given before each treatment may loosen the secretion and render its evacuation easier. The manœuvre is reminiscent of the late Dr. Tucker Wise's postural method[3] of treating phthisis designed to promote drainage of the bronchial tree. He encouraged his patients to lie for half an hour three times a day on an inclined plane with the head lower than the hips, and the gratifying results he obtained were no doubt due to the relief afforded by the maintenance of a free airway.

It is rather unusual to give treatment by inoculation to young children in this country, but Haibe,[4] director of the Bacteriological Institute at Namur, considers it very important to treat asthma vigorously as early as possible before permanent damage has been done. He claims a 90 per cent. recovery-rate in young children with asthma after treatment by the application of antivirus to the nose, and the subcutaneous injection of autogenous vaccines made from sputum. The antivirus was a stock preparation made from a variety of organisms isolated from patients with asthma. When the patient was too young to bring up sputum, material for the preparation of the vaccine was made from swabs from the larynx. In this country we may not be so sanguine about the action of antivirus as our French contemporaries, but in any effort to clear the respiratory system the nasal passages should not be neglected, and the use of nasal sprays or the displacement technique of Proetz should be remembered.

INDEX TO "THE LANCET," VOL. I., 1935

The Index and Title-page of Vol. I., 1935, which was completed with the issue of June 29th, is now ready. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of The Lancet, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

ANNOTATIONS

LIFE WITHOUT BREATHING

Singh reports [1] that a dog has been kept alive for 16 minutes without breathing oxygen through the lungs; it was supplied with oxygen intravenously while under an increased atmospheric pressure amounting to three atmospheres. This crucial experiment was ended abruptly by pulmonary embolism, the result of a fault in the injecting apparatus which allowed a sudden gush of oxygen into the veins. Otherwise there seems no reason why it should not have continued much longer; and herein may lie the germ of an important advance in oxygen therapy. Previous workers have injected oxygen into the veins, but in human subjects there is known to be a grave risk of pulmonary embolism if the rate of injection exceeds about 0·75 c.cm. per kg. of body-weight per minute. While it has been suggested that small quantities given at intervals might provide useful means of oxygen administration, this method has not so far been scientifically justifiable in the treatment of anoxæmia. Singh has investigated its possibilities in two stages. First he determined the dose of oxygen that could be absorbed intravenously under ordinary atmospheric pressure. He found that cats could absorb about 5 c.cm. of oxygen injected in about ten minutes, and that other animals of different species could take larger doses in relation to their weight. The amount of gas absorbed depends on various factors including the distance between the point of injection and the heart and lungs, and the calibre of the veins along which the bubbles travel. But it was clear from the experiments that, owing to the limitations imposed by the calibre of the available veins and the rate at which the oxygen can be carried away, injection at ordinary atmospheric pressure can supply only a comparatively small proportion of an animal's oxygen requirements. Singh therefore proceeded to repeat his observations within the pressure chamber at the premises of Siebe, Gorman and Co. At an increase of one atmosphere it proved possible to inject intravenously 30–40 per cent. of the oxygen required by a cat without any harmful effects, and at two atmospheres about two-thirds of the oxygen required by a dog was introduced. The crucial experiment, as already stated, showed that at a pressure of three atmospheres the whole of a dog's oxygen requirements could be met by intravenous injection. It was, of course, necessary for the complete experiment to be performed in the pressure chamber, and the operator had himself to work there. During the injection the dog's respiration was almost normal; a soda-lime tube attached to the trachea, and leading to a rubber bag absorbed the expired carbon dioxide.

The theoretical likelihood that under positive pressure enough oxygen can be injected to meet all the needs of an animal has thus been justified in fact. The application of this finding to problems of chest surgery, resuscitation, and the relief of anoxæmia is the next, and obviously very difficult, step. An alternative route for the supply of oxygen when large areas of normal aerating surfaces of the lungs are put out of action by, for example, a diffuse broncho-pneumonia would get over difficulties at present insurmountable (except in milder cases where the oxygen-tent is very useful). Injection of the gas, if it proves practicable, should be a valuable means of coping with respiratory failure of this type.

AIRCRAFT AND YELLOW FEVER

THE risk of yellow fever spreading to parts of the world at present immune from this disease has been much increased in recent years by the development of aerial transport, and public health authorities are everywhere becoming alive to the danger. One side to the problem of diminishing this risk consists in preventing the transport of the mosquito vector, *Aedes ægypti*. In a communication in the monthly bulletin of the Office International d'Hygiène Publique for July, Dr. C. L. Williams and Dr. W. C. Dreesson, of the United States public health service, confine themselves to this aspect of the subject. They dismiss as impracticable the frequent fumigation of aircraft with hydrogen cyanide; fumigation with "carboxide" (ethylene oxide and carbon dioxide) they find not to be satisfactory on account of the great weight of necessary apparatus and the high concentration of this gas required to kill mosquitoes; and they finally recommend a concentrated extract of pyrethrum (2 per cent. of pyrethrin in light oil) distributed by an atomiser in a very fine cloud at the rate of 2 to 4 grammes per 1000 cubic feet. That such a method, applied with care and conscience, should destroy all the mosquitoes on board there is no reason to doubt. But that such a method should be necessary at all is a sorry reflection on the state of the sanitary organisation at the aerodromes in question. To free the native quarter of a city from *Aedes ægypti*, or to control it completely in a seaport full of small craft and lighters, is admittedly not an easy matter. But there is no reason whatever why a well-planned aerodrome with an efficient sanitary gang should produce a single specimen of this purely domestic mosquito.

AVOIDANCE OF REACTIONS AND FAILURES IN DIPHTHERIA IMMUNISATION

ACTIVE immunisation against diphtheria, when carried out in residential institutions, implies, or should imply, preliminary Schick tests. In clinics, however, practical considerations may compel the omission of the test or impose a single reading which is usually made a week after its performance. In either event the medical officer is deprived of the evidence of protein sensitivity afforded by the appearance of the transient pseudo-element. A pseudo-positive reactor to the test is likely to be a reactor to the prophylactic, the dosage of which may be modified accordingly. To provide an *indicator of sensitivity to protein* contained in the prophylactic the Moloney test, the *intradermal* injection of a minute dose of diluted toxoid, has been used upon a large scale in Canada and advocated in this country. Dr. Chesney [1] considers that this test, although desirable, is a troublesome procedure in practice; and it is one which, it may be added, Swyer [2] found *to be not* an accurate index either of the *liability to, or severity* of, the reactions to be expected after the injection of formol-toxoid in the case of young adults. Further evidence as to the reliability of the test in children will doubtless be forthcoming, but Chesney prefers to employ what he terms the "detector dose," a preliminary dose of formol-toxoid injected *subcutaneously*. Several batches of toxoid of varying but high antigenic value (but of different origin and dosage to the toxoid used by Swyer) were employed by Chesney in the immunisation of over 700 children. For children up to fourteen years of age a preliminary detector dose of 0·2 c.cm. of toxoid was injected; this was reduced to 0·1 c.cm. for those over fourteen. Usually no local redness or tenderness followed the injection of 0·2 c.cm. of formol toxoid; occasionally an area of redness 1–2 cm. across resulted and rarely one of 2–5 cm. After the detector dose, which "contains 200 times the amount of toxoid used for the Moloney test and in itself acts as a primary stimulus," two doses of the prophylactic were injected subcutaneously at fortnightly intervals. Non-reactors received, presumably, two full doses of 1 c.cm. of toxoid; slight reactors, 0·4 c.cm. and 0·6 c.cm.; but the particularly sensitive were injected with toxoid-antitoxin floccules (T.A.F.). Among a group of 332 children only 10 reacted to the detector dose to such a degree as to make it desirable to change to this preparation, which is of high antigenic value and causes but few and slight reactions even in adults.

[1] Chesney, G.: Ann. Report M.O.H. Borough of Poole, 1934, p. 15.

[2] Swyer, R.: THE LANCET, July 6th, 1935, p. 22.

Chesney now uses a formol-toxoid of 58 Lf. per c.cm. in a routine dosage of 0·6 c.cm. and 1 c.cm. at fortnightly intervals following the detector dose. He states that the number of Lf. units in this course of injections is "in excess of that contained in three 1 c.cm. doses of the formol-toxoid generally used in this country." Reaction to the dose of 0·6 c.cm. is followed by a dose of the same magnitude instead of the full final dose of 1 c.cm. The proportion of Schick-immunes produced by this method and this prophylactic appears to be very satisfactory, immunity to Schick-negative level being attained in more than 90 per cent. in a few weeks. Chesney thinks that the occurrence of clinical diphtheria, caused by the gravis strain or a heavy infection with a milder strain in a few persons who had previously been immunised and found to be Schick-immune to the ordinary test, suggests that the level of immunity thus indicated may not be sufficiently high. He has therefore made some observations with a more potent Schick toxin supplied by Dr. R. A. O'Brien. This preparation, although containing no more free toxin than the standard fluid, had four times its combining power, owing to the presence of "toxoided" toxin. Tests with the two preparations were made simultaneously upon a group of 45 children who had received a course of formol-toxoid. In 5 cases (11·1 per cent.) the readings were positive to the fourfold test: of these, 4 were negative to the standard test and 1 was positive. The remaining 40 children were negative to both tests. From the results in this small series Chesney draws the rather sweeping conclusion that "in every hundred children in his area treated with the prophylactic course, there are two or three who fail to develop immunity of the level indicated by the standard Schick [test] and a further nine who are not satisfactorily immune in spite of their negative reading to the standard Schick test, and that this 9 per cent. are the Schick negative children whose 'Schick immunity' will break down before a heavy or markedly virulent infection."

It would have been interesting and possibly instructive if this group of 5 children had been tested again with the fourfold Schick toxin a week later. It may be suggested that some at least who were at first positive to the fourfold test would, as the result of the secondary stimulus thereby provided, have become negative reactors. Whether the secondary stimulus of Glenny be Schick toxin or the diphtheria bacillus itself, its effect

SYPHILITIC AORTITIS

It has been suggested in Germany that syphilitic aortitis is alarmingly on the increase, and Dr. C. Müller,[1] of Oslo, has been studying the post-mortem records of the Ullevaal communal hospital to see whether the German conclusions are applicable to Norway. His material covers the period 1905–33, and consists of 14,258 autopsies, at 455 of which syphilitic aortitis was found (3·2 per cent. of all the examinations). Though there was a large increase in the annual number of such cases during the 27-year period under review, this is fully accounted for by the increase in population, and Dr. Müller suspects that the German findings merely reflect a change of fashion in diagnosis and nomenclature. Of 244 Norwegian cases of syphilitic aortitis diagnosed as such post mortem between 1920 and 1931, about two-thirds were complicated by such conditions as aortic insufficiency and aneurysm. The correct diagnosis was made clinically in only 36 per cent., the complicated cases being recognised in 51 per cent., and the uncomplicated in only 6 per cent. These are figures disconcerting to even the most hardened clinician, and Müller indulges in calculations showing how many of the diagnostic oversights could have been avoided by systematic examination of the patient. In only 50 of the 244 cases had an attempt been made to obtain a history of syphilis; and only in 62 per cent. had the Wassermann reaction been tested. Other serological tests might also have been exploited more fully, although some 20 per cent. of the cases under review proved to be sero-negative. Müller also pleads for the more general and regular use of X rays, and a more comprehensive study of the clinical picture. It is not enough to rely on a diastolic murmur over the heart, for this was observed in only two-thirds of his cases of aortic insufficiency; a systolic murmur is, in his experience, at least as common as a diastolic murmur in such cases. The patients with neurosyphilis in his post-mortem material died comparatively early, presumably because syphilis of the nervous system runs a more rapid course than syphilis of the aorta, the prognosis of which is not altogether desperate. Indeed, less than half of the Ullevaal patients suffering from syphilitic aortitis died of disease of the heart or aorta. The average age at death was between 56 and 57, and over 12 per cent. of all the patients were more than 71 years old. There was even a handful of octogenarians among them. Aneurysms proved less fatal than might have been anticipated, for only 19 per cent. of their owners died from rupture of the aneurysm or pressure exerted by it on the surrounding structures.

SHIVERING

Some interesting experiments on shivering are reported [2] from the National Hospital, Queen-square, comprising observations both on normal persons and on patients with selected nervous lesions. The condition was produced by immersing the legs first in a warm and then in a cold bath, rectal and skin temperatures being recorded meanwhile from thermocouples suitably placed. The thermocouple in the rectum was 5 cm. from the sphincter, and almost certainly gave the blood temperature. This fluctuated surprisingly, rising by about ½° during the warm bath and falling about 1½° during the cold. In the normal subjects shivering started shortly after the change of bath and stopped after a change in the reverse direction.

Although the long latent period—three minutes or so in each case—was against a reflex originating in the skin, there was nothing definite in the records to exclude this. Their most striking feature, nevertheless, was the close association of onset and cessation of shivering with the peak and trough of blood temperature respectively, suggesting that a change in this temperature was the effective agent. This theory was confirmed by the case of the paraplegic patient who showed similar changes in blood temperature and similar shivering reactions, but in whom reflex effects were excluded by the fact of the stimulus being confined to the legs, innervated from below the lesion, and the shivering to the upper parts of the body, innervated from above the lesion. Afferent stimuli were further eliminated by the observation that a patient with a lesion of one thalamus and corresponding loss of sensation from the opposite half of the body responded in the same way as a normal person. There is therefore little doubt that shivering, or its cessation, is the result of a change in blood temperature, although the actual level at which this takes place seems to be of minor importance. The efferent path of the motor impulses must start from a localised part of the central nervous system, for if the change in blood temperature acted on all the spinal segments shivering would take place below the level of a transverse lesion—which, as we have seen, does not happen. The origin of the impulses has not been located, but there is evidence that they are transmitted by the extrapyramidal tracts of the spinal cord, shivering having been found absent in one patient below the level of an operative section of the spinothalamic tracts; the actual spinothalamic lesion could not produce this effect, there was no evidence of involvement of the pyramidal tracts, and other cases (hemiplegic) had shown that shivering could occur, apparently normally, after considerable damage to them. This impression as to the extrapyramidal nature of the impulses was strengthened by the finding that damage to the cerebellum had a distinct influence on shivering, converting the ordinary clonic movements into choreiform movements. The investigators point out that shivering occurs from other causes, such as emotion and fever, and we hope they will extend their studies to these conditions.

ADHESIVE STRAPPING AND THE PATCH-TEST

It is unfortunate that so useful a preparation as adhesive strapping is often the cause of an irritation dermatitis; and as a rule the more efficient the strapping the greater the risk of dermatitis, elastic adhesive strappings sometimes giving an incidence as high as 25 per cent. Much of this dermatitis is mechanical in origin, arising from the tackiness of the application, and is comparable with the eruptions provoked in bakers by the sticking of dough to the skin. This type of dermatitis from adhesive plaster is not serious and readily subsides under suitable and simple treatment. A few cases, however, are traceable to an allergic sensitiveness towards one or other of the ingredients of the plaster, and this is more awkward, since limited contact may give rise to acute and distressing lesions which may persist for weeks. Schwartz and Peck [1] have investigated this problem by patch-testing over a hundred employees engaged in the manufacture of adhesive tape. They find that the resins employed are common causes of allergic dermatitis—all of 13 cases showing the condition were resin-sensitive—and that rubber is an occasional cause. This has been recognised by manufacturers, but efforts to find a non-irritating resin have not yet proved successful. In employing adhesive strapping for ordinary patch-tests one must bear in mind the possibility that the strapping itself may cause irritation and so obscure the results.

Elastic adhesive plasters probably find their greatest use in treatment of gravitational affections of the legs, but recent writings suggest a tendency to abandon the valuable technique evolved by Dickson Wright,[2] partly because dermatitis is a common sequel. This hazard can usually be avoided however by some simple expedient such as the application of the bandage over a protective covering like lint, gauze, cotton stockings, or zinc-gelatin paste. Another simple method, which can always be adopted in making patch-tests and is often suitable for legs, is the application of the elastic bandage reversed so that it does not adhere to the skin but to itself.[3]

The patch-test is now a routine examination for specific skin sensitiveness but not all workers subscribe to the same technique, and it seems desirable that standard conditions should be observed to allow a fair comparison of results. Enough work has been done to show that patients actually suffering from a sensitisation dermatitis will react immediately to a patch-test with the causative agent. Those who are not actually suffering from a dermatitis but are being tested for possible sensitiveness may show a reaction delayed not only for 24–48 hours, as often supposed, but for as long as 14 or even 24 days.[4] [5] This means that observation should be continued at least a month after routine investigations such as those described by Schwartz and Peck. Further, the patch-test is meant to demonstrate *allergic* sensitiveness and only a limited contact should be necessary to provoke such a reaction. The usual 24-hour application is if anything on the generous side, and has indeed been known to produce a simple traumatic reaction which tends to confuse the issue. It should certainly not be necessary, and seems undesirable, to leave patch-tests in place for 48 hours as suggested by these writers and by others recently.[6] For the same reason it is questionable whether a covering of gutta-percha or oil-silk over the patch-test is an advantage.

MALARIA AND HOOKWORM

As one of the lessening number of those who saw the early stages in the fight for the prevention of malaria, Sir Malcolm Watson has put on record [7] something of what has come within his own knowledge and experience during a time when, so he puts it, the spirit of high adventure filled the veins of medical men of many races. The opening of the story is taken up by an account of his noted attack on malaria at Klang and Port Swettenham in 1901, the fight seeming to be almost without hope in view of the high temperature, the rainfall of 100 inches a year, and the amount of swamp and tropical vegetation round them. So much was this the case that the High Commissioner had wired ordering that the work in the port should come to a stop, a decision which Sir Malcolm was happily able to have put on one side. The proof of the value of his public health work there, judged by the touchstones of hospital and laboratory, was seen between 1901 and 1905 in a fall to one-eighth in the deaths from fever and to one-third in those from other diseases. This last effect was completely unlooked for and a special point is made of it, but the parallel outcome in the case of hookworm infection will come to mind. Sir Malcolm put to Wickliffe Rose of the Rockefeller Foundation the suggestion that too much was being made of the hookworm in the tropics—seeing that in his experience 50 worms, the number usually present at post-mortem in Malaya, did no damage to the man who harboured them—and that the pushing of a campaign against this infection at the same time as one against malaria would be too much for the Malayan mind; and he then notes a finding from the Report of the Uncinariasis Commission to the Orient[8] that fewer than 100 hookworms did no damage to the infected person. It is true that in a group from a penal institution this was so, but the report says clearly that in the kampongs there was "a progressive fall in hæmoglobin values from the 100-worm group to the 0-worm group." The other side of the question is seen in the American experience in Bilibid prison after Manila had been taken from Spain; its death-rate could not be reduced below 7·5 per cent. till they got rid of the hookworms and other intestinal parasites, which the prisoners harboured; after that there was a fall to 1:35 per cent. Moreover, from Clayton Lane's recent review in our columns[9] it is clear that even to-day there is no knowledge of the lowest weight of hookworms under which man is undamaged, though he believes it is certainly under 50. When malaria and hookworm are both present in any country, only those in authority on the spot have the knowledge necessary for the giving of a decision as to which should be attacked first. But the second danger is still there and must be kept in mind.

As its title tells, most of Sir Malcolm's lecture is a discussion, and a very useful one, of the history of the control of malaria in different parts of the world by biological methods, and by the production of delicate chemical changes in environment. It contains word-pictures of Gorgas and Darling, recounts the founding of the Ross Institute and its incorporation in the London School of Hygiene and Tropical Medicine, and comes to an end with a note on Ross himself, and a statement of the belief that in his last years he felt that the world was taking advantage of his discovery and that he had not toiled and fought in vain.

THE CHARAKA CLUB

It is four or five years since a volume of the Transactions of that admirable literary society, the Charaka Club,[10] has appeared. They have always been a delightful medley of wit and wisdom, and those who are fortunate enough to possess the previous issues will be delighted to find that the literary vitality of the club is admirably preserved. The contents of the volume, as of its predecessors, are extremely varied, and of these the following may be mentioned as examples: Dr. S. W. Lambert supplies a learned reading from Vesalius, with facsimiles of the second printed edition and many illustrations. Dr. G. L. Walton has an essay on composition with the camera, admirable photographs explaining how an inside knowledge of photographic technique may assist the intensive study of pictures. Dr. Francis Packard introduces us to the earliest surgical case book of the Pennsylvania Hospital. The institution was among the first, or the first, that was founded as a hospital in the modern sense of the term, but it was not till some 50 years after its foundation that the management ordered that any records should be kept, and the original case reports run from 1803 for the next 25 years. The operations recorded are not those of the present day, mainly being amputations in the treatment of fractures and dislocations. Among the drawings at the end of the book are two representing the case of a double hare-lip before and after operation; the operation was performed by a Dr. Physik (his real name), and the results seem to have been good. Dr. Archibald Malloch writes on James de Berty Trudeau, artist, soldier, and physician, giving illustrations of his statuettes and bas-reliefs in bronze, some of them being piquant caricatures. Those who have the whole series of the Transactions will note with regret that they are reading the last contributions of Prof. George David Stuart, surgeon, wit, and accomplished poet. In a sympathetic chapter Mr. Bernard Sachs reminds us of his great personal and intellectual qualities, and his friends will endorse the tribute.

IS ENDOCARDITIS LENTA ALWAYS FATAL?

Endocarditis lenta (subacute bacterial endocarditis), though not a common disease, is relatively important, since it usually strikes young adults and, as many believe, is always fatal in the end. The fact remains that isolated cures are often reported, and one authority (Libman) even reports a recovery-rate of about 3 per cent. The possibility of applying effective treatment has lately been discussed by H. Schulten,[1] who points out that although endocarditis lenta is due to an infection of a heart valve by the *Streptococcus viridans*—or rarely some other organism—there are occasional cases, clinically very similar, in which blood culture is negative, and no bacteria can be found in the endocardial vegetations post-mortem. Possibly the cause here is acute rheumatism, but whether or not this is so the recovery of such a case could not, Schulten thinks, be classed as a cure of endocarditis lenta; he seems to regard a positive blood culture as essential to diagnosis. Evidence of long-standing disease or congenital defect of the valves is also held as a rule to be a sine qua non, but it is believed that very exceptionally these may be absent—e.g., in endocarditis of the heart wall—or very slight. Schulten draws attention to another important feature of subacute bacterial endocarditis which may lead to a false idea of its curability—namely, the long remissions. It is now known that temporary improvement may be so great that the patient is able to resume his ordinary work, perhaps for several months; but almost without exception it is sooner or later followed by relapse and death. Treatment is divided by Schulten into two groups: (1) causal, which includes chemo- and sero-therapy, immuno-transfusion, vaccines, protein shock, and the surgical treatment of the presumed primary focus; and (2) symptomatic, including treatment for anæmia, the circulatory system, and antipyretic measures. In 23 of his own cases where a variety of these remedies were used, the patient always died. Replies to a questionnaire sent to his colleagues elicited a somewhat unusual result—namely, complete agreement on nearly all points. The general opinion was that an optimistic prognosis depended on a false diagnosis; that the mortality with or without treatment is 100 per cent., and that no therapeutic measure so far tried can alter the course of the disease. Two observers (Bingold and Lechleitner) make the suggestion that in the very early mild stage it may be amenable to treatment, but they offer no evidence in support of this belief. In short, the current opinion in Germany seems to be that the present measures used against endocarditis lenta are futile; and an important therapeutic problem remains wholly unsolved.

INJURIES OF THE CRUCIATE LIGAMENTS

IT is commonly assumed that the severest degrees of internal derangement of the knee-joint are those associated with rupture of the cruciate ligaments, partial or complete. These ligaments are so strong and their attachments so firm that there is reason to regard them as the main means of maintaining the stability of the joint. Superficial observation of the arrangement of the fibres would lead one to suppose that the anterior cruciate limits forward movement of the tibia on the femur, while the posterior limits backward displacement. Dr. Henry Milch,[1] of New York, however, thinks this a very imperfect view of the function of the cruciate ligaments. He holds that with the knee in full extension they have very little to do with stability, the collateral ligaments and the muscles being alone responsible. In flexion the action of the cruciates comes into play, some fibres of both anterior and posterior ligaments limiting backward and forward displacements on one another of the opposing surfaces of tibia and femur. Milch's observations on the results of rupture of the anterior ligament lead him to regard it as a structure of no very great importance. He has operated in cases of complete rupture of the ligament and has gone so far as to excise it completely, and he reports that its complete loss is compatible with relatively normal function of the knee-joint. Rupture of the posterior cruciate ligament is even less common, and he makes no definite pronouncement about its importance; but one gathers that he suspects this of being no greater.

The signs of rupture of the cruciate ligaments are said to be: (1) the possibility of passive displacement backwards of the tibia, or of its internal rotation, with the knee-joint in the position of extension; and (2) the possibility of displacing the tibia forward when the knee is flexed and the foot fixed. Of the first of these tests Milch says that it will never be positive if the collateral ligaments are intact; properly, therefore, it should be considered a test for injury of the collateral—more particularly the internal collateral—ligaments. The second test is reliable, he agrees, when present; but he found it positive in only 1 case out of 8. The probable explanation is that the tone of the quadriceps muscle is usually sufficient to mask the instability on which the test depends; under anæsthesia the muscle relaxes, and the "rocking" of the flexed knee-joint may then be demonstrated. The difficulty of distinguishing between injury of the cruciate ligaments and of the semilunar cartilages is shown by the number of times open operation has first revealed the lesion of the former. A tear of the internal meniscus may indeed be associated with rupture of the anterior cruciate ligament, and in one such case Milch excised both structures, with the result that on discharge from hospital the patient had a knee-joint with complete extension, flexion to 90°, and no abnormal mobility either anteroposterior or lateral.

In most cases of severe internal derangement of the knee-joint the disability, Milch believes, is due primarily to loss of integrity of the internal lateral ligament, and he recommends that treatment should be directed towards repair of this structure. In the worst cases this involves an open operation, with reconstruction of the ligament from the fibres of the fascia lata; but where the internal lateral ligament is intact he advises conservative treatment. One such case is cited in which even immobilisation was dispensed with. The diagnosis was rupture of the posterior part of the capsule, together with a tear of the anterior cruciate and fibular collateral ligaments, the last being shown by a possibility of hyperadduction to 15°. A knee cage brace was fitted, the sole and heel were raised on the outer border of the shoe, and the patient was allowed to walk about for six months. The result was good, and he now engages normally in sports.

Ski-ing accidents provide a number of these severe injuries to the knee-joint every winter, and it will be interesting to learn how far Milch's views on the relative unimportance of cruciate ligament injuries are upheld by other surgeons.

THE ESTIMATION OF IODINE

THE increasing attention which is being paid to the significance of small quantities of physiologically active materials is well exemplified by the case of iodine. The widespread occurrence of this element has long been known, but there has been a dearth of trustworthy data concerning its quantitative distribution owing to the lack of uniform methods of analysis. To remedy this state of affairs the Medical Research Council appointed a "Committee on Methods for the Estimation of Iodine," the expenses of which were defrayed by the Nitrate Corporation of Chile, Limited, and asked Mr. C. O. Harvey, a member of the Government Chemist's staff, to make the actual investigation. In his report[1] Mr. Harvey describes an improved and standardised method which he has devised, capable of giving consistent results when parts of the same specimen are tested by independent analysts. He sets out precise details for carrying out the analyses, with the various modifications required for the different materials analysed. Emphasis is laid on unsuspected pitfalls such as the necessity for employing pure nickel dishes in place of those containing copper alloyed with the nickel or even platinum dishes; strict precautions are necessary for avoiding contamination from impure chemicals or from laboratory air, and the titrations must be carried out on a bench not used for the other operations described. Promotion of further work on iodine in relation to the nutrition and health of man and animals, in which Mr. Harvey's method is likely to prove useful, has been entrusted to a new committee, appointed jointly by the Medical Research Council and the Agricultural Research Council. A reliable method of estimating the iodine content of the blood may well afford material for a more effective attack on hyperthyroidism.

THE death is announced on August 8th of Mr. Hugh Walker, ophthalmic surgeon to the Victoria Infirmary, Glasgow.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXV.—PROGNOSIS IN CONGENITAL STENOSIS OF THE PYLORUS

IN congenital stenosis of the pylorus we can recognise definite pathological changes, although the underlying cause is not yet clearly understood. The main feature, as is well known, is a marked hypertrophy or local gigantism of the circular muscle-fibres of the pyloric canal, which manifests itself by obstructive symptoms, usually at the age of about three weeks, and results in gradually increasing dilatation and hypertrophy of the walls of the stomach.

Of the two methods of treating congenital pyloric stenosis, recent experience has shown that medical treatment is uncertain in its results, requires a considerable period of time and, if unsuccessful, may lead to a grave state of malnutrition. It is now almost universally agreed that operation is the most satisfactory method of treatment, and we would emphasise, therefore, that in this article we are discussing the prognosis in cases treated surgically.

DIFFERENCE BETWEEN PRIVATE AND HOSPITAL CASES

The parents of an infant with pyloric stenosis demand first, an opinion on the chances of that particular infant surviving the operation; secondly, they are concerned with the ultimate prognosis, or, in other words, with the end-results of treatment, provided the infant survives the immediate risk. The factors governing operative prognosis in this condition are complex and probably not entirely understood, but it is the general experience that the outlook is much more hopeful in the private than in the hospital case. If we can find the reasons for this difference between hospital and private cases, we may be enabled to discover important factors which have a bearing on the immediate prognosis. How does the hospital case differ from the private case? At birth there is probably no difference at all, both infants apparently being strong and healthy, and not infrequently above the average birth weight. It is after the characteristic symptoms have commenced that the difference manifests itself. The mother of the infant which is ultimately brought to hospital is frequently harassed and preoccupied, and the fact that her baby is vomiting occasionally may not at first give rise to any serious concern. Eventually, perhaps on the prompting of a neighbour, she will decide that her breast milk is not agreeing with the child, and various feeds are tried in quick succession in a vain attempt to find something "which suits baby's stomach." The medical profession is not altogether blameless in this respect, since it is not always the interfering but well-meaning neighbour who advises the mother to wean her infant. Finally, after several weeks have elapsed, during which time the infant has been going rapidly downhill, he is brought to hospital in a state of extreme inanition, and operation is fraught with serious risks. It is this long delay which is so disastrous in a high percentage of hospital cases, since it means not only that at operation the child's resistance is at its lowest ebb, after weeks of starvation, but also that thereafter he is irrevocably deprived of his mother's milk which has long since dried up. It is little wonder that the mortality-rate in such cases is high.

The well-to-do mother has more leisure and can usually observe her infant more closely and, perhaps, though not always, more intelligently. Further, she is apt to be far more exacting in her demands on her medical attendant; he is likely to be summoned at the first sign of trouble, and she does not hesitate to demand a second opinion regarding her infant if she is not completely satisfied. This attitude reacts favourably on the infant, since it means that the pyloric obstruction will probably have been diagnosed and treated at an earlier stage than has that of the hospital infant, the child will not be so starved and dehydrated when it comes to operation, and, furthermore, the mother's milk will still be available at the critical post-operative period—a point of extreme importance. We believe that the mother is the best custodian of her infant in sickness or in health, and the very fact of removing an infant from its mother and placing it in the strange, somewhat impersonal atmosphere of a hospital, may do much more harm than is generally realised.

Here, then, are factors which may serve to guide us in giving an opinion regarding the immediate prognosis in any particular case. We must ascertain the duration and severity of symptoms, we must note the infant's general condition, and we must determine whether breast-feeding is going to be possible after operation. If these crucial questions have to be answered unfavourably, prognosis must be very guarded, since the mortality-rate may be 20 per cent. or even higher. If, on the other hand, the answers are favourable, we are justified in giving a favourable prognosis since, in our experience, the mortality-rate in this type of case is extremely low. In the experience of one of us (G. H.) over a number of years, the mortality-rate in hospital cases of pyloric stenosis is rather more than 20 per cent., whereas no private case has been lost, and we suggest that this remarkable difference may be explained to a large extent by the factors outlined above.

TECHNIQUE OF TREATMENT

The question of operative technique must, of course, have a bearing on the immediate prognosis, and although the Rammstedt operation, now generally adopted, is a comparatively simple procedure, it should, wherever possible, be performed by a surgeon who is experienced in children's surgery. Gentleness, combined with speed, is essential if post-operative shock is to be reduced to a minimum. A good deal of stress has been laid on the value of blood transfusion before and after operation to minimise shock and to increase the child's resistance, and in our experience this measure has been of distinct value in severe cases. Preliminary gastric lavage is desirable, and the parenteral administration of glucose-saline solution before and after operation is important owing to the dehydration which is invariably present to some degree. The great value of breast-feeding during the post-operative period has already been stressed, but if this is not possible, *frequent small* feeds should be given of some readily assimilable food such as peptonised milk. Nothing should be given by the mouth for four hours after operation. It is our practice then to give 2 drachms of glucose and water hourly for four to six hours, and thereafter an ounce of peptonised milk may be prescribed at two-hourly intervals; the amount of the feed and the length of the interval are gradually increased until by the third day after operation the infant is receiving a feeding appropriate to its age and weight. Close attention to details of feeding and general management during the few days subsequent to operation is of extreme importance. The method of anæsthesia adopted does not appear to affect the issue, since in our series of cases both general and local anæsthesia have been tried and the mortality-rate has remained fairly constant. We do, however, favour local anæsthesia, supplemented, when necessary, by gas-and-oxygen.

POST-OPERATIVE COMPLICATIONS

Of the post-operative complications, the most frequent and most dreaded is *enteritis*. Here, again, it may be said that enteritis scarcely ever occurs in the private case, and its occurrence is probably governed by the same factors as influence operation mortality. Other complications such as *hyperpyrexia* and *hæmorrhage* are fortunately very rare, and their effect on prognosis is therefore *negligible*.

ULTIMATE PROGNOSIS

With regard to the ultimate prognosis in those infants who survive the operation and the post-operative convalescence, the problem is fortunately a simple one. We can confidently assure the parents that their child will grow up as any other child, and that no disability will mar its later life as a result of the congenital defect treated in infancy.

SUMMARY

At the present time the lives of many infants of the hospital class suffering from congenital pyloric stenosis are needlessly lost owing to long delay in diagnosis and unnecessary weaning, and until the possibility of this condition is considered in every infant with persistent vomiting, constipation, progressive loss of weight, and visible gastric peristalsis, prognosis must remain very guarded. The satisfactory results obtained with these cases in private practice, where circumstances permit of earlier diagnosis, serve to emphasise the fact that the mortality-rate for all cases is capable of being reduced to a very low figure, and we must hope that in the not too distant future it will be possible to predict with confidence a favourable outcome in the vast majority of infants with pyloric stenosis, irrespective of the class of society to which they belong.

SPECIAL ARTICLES

THE EFFECT OF INFLUENZA EPIDEMICS ON THE CERTIFIED CAUSES OF DEATH

BY PERCY STOCKS, M.D. Camb., D.P.H.
MEDICAL STATISTICAL OFFICER, GENERAL REGISTER OFFICE, LONDON

THE idea that epidemic influenza usually occurs a "*setting*" of associated strange fevers, agues, r dyspepsias finds a place in the writings of several pidemiologists and the association between influenza prevalence and that of certain other diseases with somewhat ill-defined respiratory, nervous, or gastro-intestinal symptoms has been stressed especially by Sir William Hamer.[1]

The 1918–19 epidemic in England and Wales was carefully studied in a Supplementary Report of the Registrar-General[2] with a view to leaving a permanent record of the manner in which deaths said to have resulted from influenza alone or in combination with other causes were certified, and a general broad estimate was also made of the contemporaneous deaths attributed to phthisis, pneumonia, bronchitis, and heart disease which probably resulted from the epidemic waves. This latter effect upon the certification of deaths from other causes individually could not be assessed from the experience of a single year, but experience has now accumulated of more recent epidemics—notably in 1922, 1927, 1929, and 1933, and it seemed worth while to try to determine with more definiteness what happens to the mortality as described on death certificates during the months when influenza is highly prevalent.

If influenza waves tend to be accompanied by an increased activity of other infections having some kind of affinity for influenza, or by a condition of the population rendering it more liable to succumb to other diseases, this should be evidenced by an increase over expectation in the mortality attributed to these other causes during influenza epidemics. The same thing would happen, however, with regard to chronic pathological conditions if superimposed influenzal infection frequently led to death which would otherwise have been postponed, provided that in many such cases the superimposed influenza was not recognised as such or not thought worthy of mention on the death certificate. If, on the other hand, there is any truth in the statement, sometimes made by persons who are themselves immune to influenza, that "an influenza epidemic can be created by talking about it," the implication being that once the medical profession has decided that an epidemic has begun many ill-defined causes of illness and death will be attributed to influenza, thus exaggerating the wave of prevalence or mortality assigned to it, we should expect to find that during epidemics the deaths attributed to such other causes would show a compensatory decline rather than an increase.

Collins,[3] in an instructive study of weekly influenza and associated mortality during 1918–29 in a group of 35 cities of the U.S.A., found that in the pandemic of 1918–19 about 8 per cent. of the excess mortality from all causes was credited to causes other than influenza or pneumonia, in the 1920 epidemic 23 per cent., and in the minor epidemics since 1920 about 40 per cent. About half of this excess mortality was attributed to other causes, with influenza or pneumonia stated as contributory, the remaining half having no mention of influenza or pneumonia, but being attributed to conditions such as heart disease, nephritis, cerebral hæmorrhage, phthisis, or bronchitis. As will be seen below, analysis of mortality in England and Wales during 1921–32 by months leads to a similar general conclusion, though the different precedence given in the two countries to influenza and pneumonia when stated in combination with other causes precludes exact comparison. The present analysis, however, has been carried out for each of some 45 causes separately in the endeavour to ascertain which particular causes show the most pronounced sympathetic increase in mortality during influenza epidemics and which are unaffected, and to seek a reason for this.

Winter Influenza since 1920

Since the pandemic of 1918–19 influenza epidemics in England and Wales have shown a decided preference for the first quarter of the year, as may be readily seen from the diagrams for London produced by Mr. Spear in his recent paper.[4] In the 52 quarters from mid-1920 to mid-1933 the deaths assigned to influenza in England and Wales ranged from 2306 to 23,927 in the first quarters, but never exceeded 4015 in the second, 705 in the third, and 2362 in the fourth. Only in 1923 and 1926 were the first quarter's deaths exceeded by those in any other quarter (the second in each instance). Dealing with the separate months of the first quarter, the distribution of the 39 months of January, February, March, in the 13 years 1921–33 according to the number of influenza deaths which occurred is shown in Fig. 1 and Table I. To facilitate subsequent reference an arbitrary division has been made into "normal" months, defined as months having up to 2000 influenza deaths, "mild" epidemic months with 2001–4000, "moderate" epidemic months with 4001–7000, and "severe" epidemic months with over 7000 deaths.

TABLE I

Distribution of Months of First Quarters of 1921–33 *according to Number of Influenza Deaths* (*England and Wales*)

—	Deaths.	January.	February.	March.
"Normal"	Up to 1000	1921, 1923, 1926, 1930,	1923, 1926, 1928, 1930,	1923, 1930.
	1001–2000	1924, 1925, 1928, 1931.	1921	1921, 1922, 1926, 1928, 1933.
Mild epidemic.	2001–3000	1929	—	1932
	3001–4000	1927, 1932	1925, 1931, 1932	1925
Moderate epidemic.	4001–5000	—	1924	1927, 1931
	6001–7000	—	1922	1924
Severe epidemic.	7,001–8,000	—	1933	—
	9,001–10,000	1922	1927, 1929	—
	11,001–12,000	1933	—	1929

There were two Januaries in the moderate or severe categories, but February attained that level in five years and March in four. In 1933 January had 11,502 deaths attributed to influenza (the only month giving a higher total being March, 1929), whilst February recorded 7135 deaths.

When the 13 Januaries from 1921 to 1933 are arranged in order of influenza death-rate, it is found that the daily mean air temperature in England and Wales in the five months with highest influenza-rate was 39·4° F., whereas for the five months with lowest influenza-rate it was 42·5° F. For February the mean temperatures were, for the 5 highest influenza months 38·5° and for the 5 lowest 41·7°, whilst for March the corresponding figures were 41·9° and 43·6°. In view of this association between coldness and influenza mortality in the winter months, which might lead to erroneous conclusions, especially when respiratory diseases are under consideration, the analysis from which Fig. 2 has been drawn was carried out by separating the 36 months of the first quarters of 1921 to 1932 into two groups of (1) 18 warmest months for which the curves are continuous lines, and (2) 18 coldest months shown as broken lines. In Table II., however, each month, January, February, or March, has been treated separately and no division into cold and warm months has been made. These two analyses relate to the 12 years ending with 1932, the figures for 1933 not being available when the work was commenced.

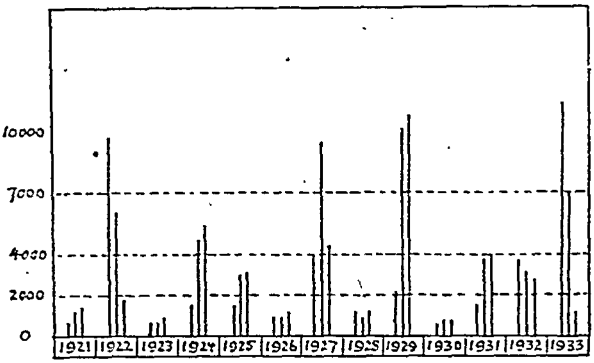

FIG. 1.—Influenza deaths in January, February, and March of each year 1921–33, in England and Wales.

METHOD OF ANALYSIS

The method of calculation was as follows. The number of deaths expected in each month was first calculated by assuming that the upward or downward trend of annual deaths from a given cause, owing to population increase, changes in prevalence, fatality, diagnostic accuracy or fashions in certification, proceeded in arithmetical progression during the period, and was represented by a straight line drawn through points having as ordinates the mean annual deaths in the quinquennium 1921–25 centred at 1923 and the mean annual deaths in 1926–30 centred at 1928. The total January deaths from the given cause in the decade 1921–30 were then assumed to be subject to the same fractional annual increment or decrement as the total deaths for the years as a whole—that is to say, the slope of the expected trend was assumed to be the same for each individual month as for the whole year. For a few causes, such as infantile diarrhœa, this would not be a safe assumption, but for the causes in Table II. there seems no reason why the general expected trend should be different for one month than for another. Thus the expected January deaths were represented by a straight line passing through a point whose ordinate, erected between 1925 and 1926 on the time scale, was equal to the mean January deaths in the decade 1921–30, the slope of the line being as determined above for the years as a whole. The annual decrements or increments thus calculated from the decade were assumed to continue constant until 1932, the straight line being prolonged to that year. Fluctuations above or below this expected datum line were assumed to be due to factors not progressively changing during the period but fluctuating from month to month and year to year, such as meteorological conditions and influenza epidemics.

At the head of Table II. the 12 years have been arranged in order of increasing influenza death-rate for the month in question and then divided into groups of three. Thus the order for the Januaries is 1930, 1923, 1921, 1926, 1928 and so on. The mean influenza-rate per million in each successive group of three months is then shown; for the Januaries it rises from 210 for the first group to 1735 per million for the last group. The actual deaths attributed to each cause in the Table were expressed as a percentage of the expected deaths in that month, and the figures shown in a given column are the means of the resultant percentage ratios for the three months named at the head of that column. That is to say, they are indices

representing the mortality experienced (corrected for the general annual trend of population and other factors affecting certification of the particular disease during the period covered) in groups of months when these have been arranged in ascending series of their influenza death-rates. In similar fashion the graphs in Fig. 2 have been drawn by arranging the 18 warmest months, out of the 36 first quarters' months in the 12 years, in order of increasing influenza death-rate, dividing into convenient groups of three or more and plotting the mean of the percentage ratios of actual to expected deaths in each group of months against the mean monthly influenza death-rate for the group. The influenza-rate represents the number of deaths per 1000 living which would occur in a year if they continued at the same rate as during the month in question. The process was then repeated for the 18 coldest months, giving the second graph.

Influenza Certified as Joint Cause of Death

Before considering [illegible] results and what they signify it is necessary [illegible] understand what diseases take precedence over [illegible] when stated on death certificates jointly [illegible] the cause of death. Of the causes [illegible] Table II. (*a*), whooping-cough, measles, diphtheria, acute poliomyelitis, encephalitis lethargica, cerebro-spinal fever, puerperal sepsis, and suicide were generally given precedence over influenza when mentioned in conjunction with it, and also in the majority of cases tuberculosis, cancer, and rheumatic fever. On the other hand, deaths from (*b*) the other causes in Table II., if mentioned jointly with influenza, would in almost all cases be assigned to the influenza group. It follows from this that when influenza is epidemic additional deaths due to influenza being superimposed on or complicated by any of the conditions (*a*), starred in Table II., would be assigned to the condition in question and would tend to enhance the deaths classed to it; and this would occur whether the associated influenza was mentioned on the certificate or not. Analysis of the deaths assigned to these causes during 1933 epidemic, in which influenza was mentioned as a complication, was carried out in order to throw more light upon the results for this group (see below). Additional deaths brought about or hastened by influenza complicating any disorders of the second group (*b*), not starred in Table II., would be either (1) assigned to influenza if that was mentioned as an associated cause, or (2) assigned to the other cause if influenza had not been recognised or mentioned as a complicating condition. In the event of alternative (1) the actual deaths classed to the cause in question would thereby tend to be *diminished* during influenza epidemics, but in the event of alternative (2) they would tend to be *increased* during epidemics. If a net increase is observed for one of these (*b*) causes it must be concluded that the number of additional deaths from that cause associated with the epidemic, but for which influenza was not recognised as a complication or not mentioned on the certificate as such, exceeded the number in which it was so recognised and mentioned.

Whooping-cough Mortality during Influenza Epidemics

Whooping-cough and measles present remarkable contrasts both in Table II. and Fig. 2, for whilst whooping-cough mortality was more enhanced by coincident influenza than any other of the causes examined, measles ortality was not enhanced, t on the contrary tended be slightly less during uenza epidemics. The ect of influenza on whoopg-cough deaths was evident alike in January, February or March; thus in the groups of months of lowest influenza-rate the actual deaths were only 54 per cent. of those expected for January, 63 per cent. for February, and 61 per cent. for March, whereas in the groups of months of highest influenza-rate the corresponding percentage ratios were 136, 180, 166. This means that deaths attributed to whooping-cough were two and a half to three times as many during severe influenza epidemics as during the same months of the years when influenza was at a low level. Fig. 2 shows that this took place whether the months were warm or cold, and with a given influenza-rate it was not enhanced by cold but rather the reverse, as shown by the relative positions of the two graphs.

When the 36 months are grouped according to the number of influenza deaths occurring, the mean deaths per month attributed to whooping-cough are shown in Table III. to increase continuously from 350 in months having less than 1000 influenza deaths to 1536 in the month having 11,838 influenza deaths. In order to ascertain the rate of increase of deaths assigned to whooping-cough and some other causes, in Table IV. the columns of Table III. have been condensed into three groups, the first (A) consisting of the 19 months (shown in Table I.) with a "normal" influenza level of under 2001 deaths, the second (B) consisting of the 13 mild or moderate epidemic months with 2001–7000 deaths, and the third (C) of the 4 severe epidemic months with over 7000 deaths.

From Table IV. it appears that for every 100 deaths attributed to influenza in excess of the "normal," during mild or moderate epidemics 7 additional deaths, or during severe epidemics 9 additional deaths, were attributed to whooping-cough. These are average figures, the number of additional deaths in a given year being naturally dependent not only upon the severity of the influenza epidemic but also upon the number of whooping-cough cases present at the time. Thus at the end of 1932

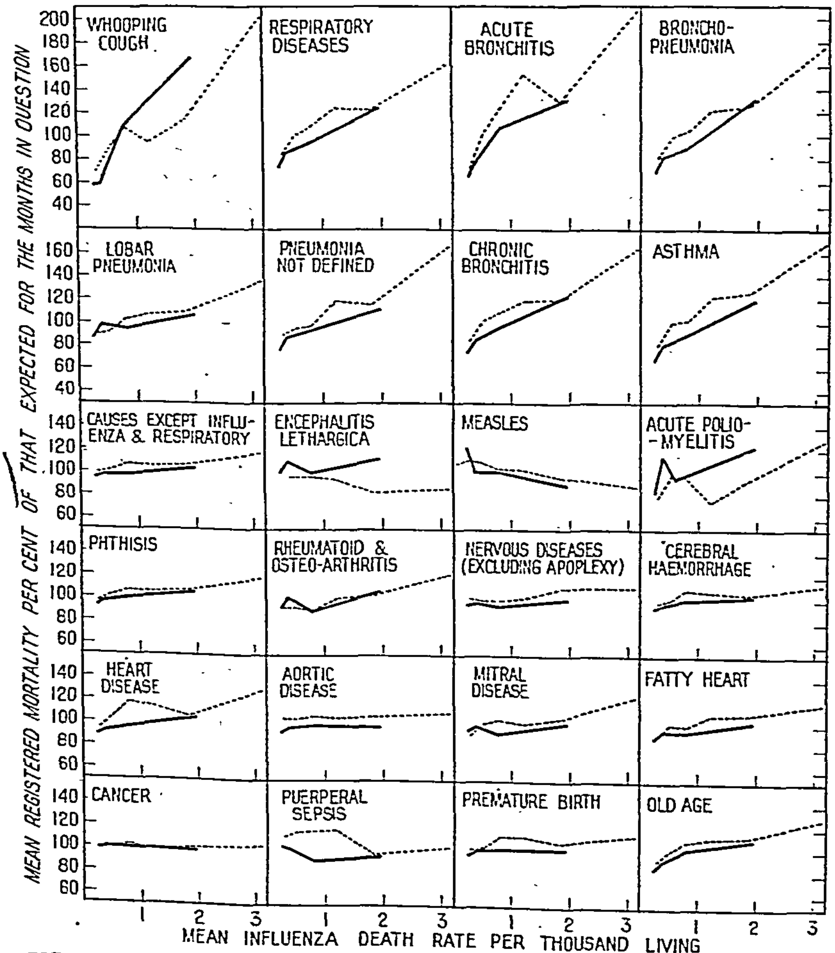

FIG. 2.—Effect of increasing influenza prevalence on the mortality attributed to various causes during the months of January, February, and March, 1921–32.

whooping-cough was presumably at a low level when the influenza epidemic began, since only 421 deaths occurred in the fourth quarter compared with an average of 628 in the preceding 12 fourth quarters. The resulting excess in January and February, 1933, due to the superimposed influenza might therefore be expected to fall short of the 9 per 100 influenza deaths averaged during the severe epidemics of 1922, 1927, 1929. Actually, as shown in Table V., the excess of whooping-cough deaths resulting in the months of January and February, 1933, above the average for the same months of 1928 and 1930 (with influenza normal) was only 327, or 2 per cent., instead of 9 per cent. of the influenza deaths. For all causes combined other than influenza and respiratory disease, the observed excess was, however, almost exactly equal to the number expected by applying the percentage rates in the last column of Table IV.

Examination of the 801 whooping-cough death certificates for January–February, 1933, revealed only 22 with any mention of influenza as a complication, so it is evident that the excessive mortality attributed to whooping-cough during influenza epidemics is not for the most part recognised as being due to a double infection. (In the fourth quarter of 1918, with its 98,280 influenza deaths, 906 whooping-ugh deaths were stated to be complicated by [illegible] in 119 instances.) It cannot therefore be oved that the influenza wave is the *cause* of the excessive mortality from whooping-cough, since they may both arise from some common factor unknown, but Fig. 2 shows that this factor could not be the rather greater coldness of the months when influenza happened to be epidemic. The explanation which most readily suggests itself is that the double infection is characterised by a very high fatality and is not usually recognised as anything other than whooping-cough with respiratory complications. The fact that in the 1933 epidemic both whooping-cough and respiratory disease mortality fell much below the expected figures, whilst other mortality reached the expected level, based on the previous severe epidemics of 1922, 1927, and 1929, suggests that it may be the *secondary* infections of influenza which spread to whooping-cough cases and prove specially fatal to them.

The absence of any similar consistent increase of deaths from measles or diphtheria during influenza epidemics suggests that the phenomenal increase of *whooping-cough mortality is of real significance* and of some epidemiological importance, and is not merely the outcome of unsatisfactory medical certification, which is *liable to be blamed* without adequate reason for anything which cannot be explained.

The occurrence of a wave of whooping-cough fatality contemporaneous with that of influenza is demonstrated in another way in Table VI., where the twelve years 1921–32 have been divided into the six years of highest influenza during the first quarter, indicated by +, and the six years of lowest influenza, indicated by —. The mean numbers of deaths during the first quarter, the two quarters coming before it, and the three quarters following, and the excess of the first quarter's deaths over the mean of those in the quarter immediately preceding and succeeding it are shown for each group.

In the "normal" years the average seasonal swing of influenza deaths was from about 600 in

Total (not influenza)	—	—	—	—	—	190	177

the summer quarter to 3600 in the winter quarter, and of whooping-cough from about 700 to 1250. In the epidemic years, with a mean influenza peak going up to 15,000 in the winter quarter, the whooping-cough swing was increased to 653, 676, 2100, 1130, 559 for the five quarters from summer to summer. Measuring by this method the excess of the March quarter's deaths over the average of the December and June quarters, it is seen in the final column that an excess of 11,435 influenza deaths was accompanied by an excess of 850 whooping-cough deaths, or about 8 per 100, as found by the previous analysis (Table IV.)

Mortality from other Epidemic Diseases in Influenza Months

Table II. shows that the association of influenza epidemics with the mortality attributed to *diphtheria* was, if anything, negative during 1921–32. Thus taking the means of pairs of columns, January gives 102 for low influenza months and 91 for epidemic months, February gives 100 and 97 respectively, and March 108 and 81. Since diphtheria was given precedence over influenza when the causes were mentioned jointly, this cannot be due to peculiarities of certification. Out of 452 diphtheria deaths occurring during the 1933 epidemic of January and February, influenza was mentioned on four certificates only as a complicating condition, compared with 40 out of 1334 in the fourth quarter of 1918.

Measles manifested a similar negative association with influenza; thus taking the mean ratios in Table II. for the six low and six high influenza months, January gives 124 and 87, February 114 and 100, March 123 and 102. The inverse relation is shown also in Fig. 2, and is difficult to account for, since measles takes precedence over influenza. Only on three certificates was influenza mentioned in conjunction with measles in 1933. It may be that when influenza is very prevalent the physician called in to treat a child with broncho-pneumonia who is stated to have had measles, often prefers in the event of death to attribute the broncho-pneumonia to influenza than to the measles he did not see, but on this point I should like to have the opinions of practitioners.

Acute poliomyelitis deaths were somewhat more numerous when influenza was epidemic in January or February, but not in March, and Fig. 2 shows no evidence of increase save in the months of very severe influenza. There is no conclusive evidence of association owing to the small numbers of deaths and of months involved. Out of 202 deaths from acute poliomyelitis during 1933 influenza was mentioned on only one certificate.

Encephalitis lethargica deaths show no consistent relation with influenza, an apparent negative effect for January and February being offset by a positive one for March. Fig. 2 shows no effect whatsoever when the months are separated into cold and warm groups, but there is evident a curious excess of deaths in the warm over the cold months when months of equal influenza are compared, which accounts for the apparent negative relation with influenza when Januaries or Februaries of all degrees of coldness

TABLE V

Excess of Deaths during the Influenza Epidemic of January and February, 1933, over the Average Experience of 1928 and 1930 with Normal Influenza Incidence

are combined as in Table II. This disease and acute poliomyelitis are the only causes in Fig. 2 to show higher rates for the warm than the cold months. During the January-February influenza epidemic of 1933 influenza was mentioned as a complicating cause on 18 certificates out of a total of 179 deaths assigned to encephalitis lethargica, and in the remaining ten months of the year it was mentioned on six certificates out of 636.

Cerebro-spinal fever deaths were more numerous in the months of February and March when influenza was most prevalent, but this was not true for January. No conclusions can be drawn owing to the fact that a strong epidemic wave of the disease occurred during 1931 and 1932 after a period of comparative quiescence.

TUBERCULOSIS

Mortality from tuberculosis of the respiratory system increased steadily and consistently with rising influenza-rate, from 92 to 107 per cent. of expectation in January, 92 to 112 in February, and 96 to 108 in March (Table II.). The graphs in Fig. 2 bring out the slight but definite effect of coldness, but show the effect of influenza to be of greater importance than that of temperature.

Table III. gives the mean numbers of phthisis deaths in groups of months with increasing influenza, and Table IV. shows that during severe epidemics more than 500 deaths per month were registered from this cause in excess of expectation founded on normal periods. To every 100 additional influenza deaths during epidemics five or six additional phthisis deaths occurred. Table V. indicates that in January-February, 1933, with excess of 16,903 influenza deaths, the expected sympathetic excess of phthisis deaths over the "normal" level, 6 per cent. of 16,903 or 1014, was almost reached, the actual excess being 856 deaths. Examination of the total 6262 death certificates for tuberculosis of the respiratory system during these two epidemic months revealed a mention of influenza on 277, or about one in three of the additional deaths which were presumably brought about by the epidemic. (The excess of deaths attributed to phthisis calculated as due to influenza in the fourth quarter of 1918 was 3854, influenza being mentioned on 1619 of these.)

Table VI. shows that whilst the March quarters of the six low influenza years produced an average seasonal excess of 767 deaths over the mean of the preceding and following quarters, for the six epidemic years this excess was 1706 deaths. It also appears that whilst the September and December quarters following the epidemics had a deficiency of deaths averaging 1090 compared with the same quarters of the years with low influenza, the corresponding deficiency for the September and December quarters preceding the epidemics was only 507. This is no doubt due to the fact that influenza itself, or the secondary infections of the respiratory tract spread by those attacked by it, hastened the death of many phthisical patients who would otherwise have lived through another summer, thereby diminishing the deaths two or three quarters later to that extent. This compensatory effect is seen in phthisis mortality statistics for the period immediately following the pandemic of 1918–19 with its phenomenal phthisis mortality.

Tuberculous meningitis mortality shows in Table II. no evidence of any increase during influenza epidemics.

RESPIRATORY DISEASES (NOT TUBERCULOUS)

Deaths attributed to bronchitis, pneumonia, or other diseases of the respiratory system following upon or associated with influenza would be classified to a subgroup of influenza under the heading "influenza with respiratory complications," and would go to swell the total influenza deaths, but would not be included in the comprehensive group of respiratory diseases. If influenza was not mentioned they would be assigned to the respective respiratory diseases and the increase of these individual groups or of the total respiratory disease group during influenza epidemics represents deaths associated in some way with the influenza wave but not recognised, or at least not stated on medical certificates, as being caused or complicated by influenza.

Table II. shows that mortality from respiratory diseases as a whole (excluding those with mention of influenza, tuberculosis, and other primary causes such as measles) increased sympathetically with influenza from 72 to 126 per cent. of expectation in January, from 69 to 149 in February, and from 80 to 145 in March. The graphs in Fig. 2 indicate that this occurred at about the same rate in the warm as in the cold months, the effect of coldness being very small compared with the effect of influenza prevalence. Table III. shows that the mean monthly deaths from these causes progressively increased from 7445 in the ten months having less than 1000 influenza deaths to 17,405 in the worst epidemic month having over 11,000. In the same series of months deaths attributed to influenza plus respiratory disease rose from 490 to 9236.

From Table IV. it appears that whilst in the A group of normal months of the first quarter 64 per cent. of influenza deaths had respiratory complications mentioned, the proportion was 71 per cent. during mild or moderate epidemics and 76 per cent. during severe epidemics. (During the fourth quarter of 1918 the corresponding proportion was 86 per cent., and during the next quarter it was 83 per cent.) Of the deaths in excess of normal expectation during this last group of months, 78 per cent. had respiratory complications. For every 100 total influenza deaths in excess of normal there was, in addition to the 73 or 78 above mentioned (included in the 100) an excess of 80 deaths during ordinary epidemics or 95 during severe epidemics attributed to bronchitis, pneumonia, or other respiratory disease without mention of influenza. (The calculated proportions in the fourth quarter of 1918 and first quarter of 1919 were 20 and 38 per 100 respectively.)

Applying to the 1933 epidemic this expectation of 95 extra respiratory deaths to each 100 extra influenza deaths, Table V. shows the expected excess over the average for the corresponding months of the normal years 1928 and 1930 amounted to 16,058 respiratory deaths, but the total excess realised was only about half of this. By the alternative method in Table VI. in the six epidemic years the mean March quarter deaths amounted to 35,947 and the mean of the preceding and following quarters to 16,119, giving an excess, partly seasonal, of 1928, whereas for the other six years the corresponding excess, which we may regard as wholly seasonal, was only 7187. The difference of 12,641 accompanied a difference of 11,435 influenza deaths, or 111 to each 100. In 1933 the excess of March quarter deaths over the mean of the preceding and following quarters was 18,317 influenza deaths, or 16,792 more than in the low influenza years, leading to an expectation of an excess of 18,639 + 7187 = 25,826 respiratory deaths over the preceding and following quarters, whereas the observed excess was 15,205. The percentage of respiratory complications amongst the influenza deaths in this epidemic was, however, 77, the average proportion from preceding severe epidemic months being 76 (Table IV.).

Influenza is of course not the only factor concerned in producing monthly fluctuations in respiratory mortality, but it is undoubtedly the most important one under present conditions, the mean temperature having only a small effect in comparison, as Fig. 2. shows. Of the various respiratory conditions acute bronchitis shows the greatest sensitiveness to influenza prevalence, as also to coldness of the month in question (see Table II. and Fig. 2). Thus for January the mortality figure ranged from 65 to 144, for February from 66 to 193, and for March from 72 to 159 with rising influenza, a range similar to that of whooping-cough. Broncho-pneumonia is not quite so sensitive, and chronic bronchitis and asthma again slightly less. The close similarity of the "asthma" to the chronic bronchitis graphs in Fig. 2 is suggestive. All of these manifest a very high degree of association with influenza. Lobar pneumonia shows a much lower rate of increase, whilst pneumonia undefined gives graphs intermediate between lobar and broncho-pneumonia, approximating closer to the former than the latter.

A higher degree of association between the respiratory deaths and the influenza deaths is found to occur when the same months are associated than when influenza deaths in January are associated with respiratory deaths in February and so on, allowing a time lag of a month or more. Thus, if the Februaries are arranged in order of the influenza mortalities in the preceding month, the ratios of Table II. for respiratory diseases become 71, 86, 130, 117, instead of 69, 75, 111, 149, and for March arrangement in order of the preceding month's influenza produces the series 79, 87, 120, 123, instead of 80, 81, 103, 145.

TABLE VII

Results of Comparison with 1918–19 *expressed per* 100 *Influenza Deaths in Excess of the Normal*

—	1918 4th quarter	1919 1st quarter	1921–32. Severe epidemics.	1933. Jan.–Feb.
Influenza, excess of normal ..	100	100	100	100
Influenza without respiratory complications	14	17	22	22
Influenza with respiratory complications	86	83	78	78
Respiratory disease, so described, estimated as due to epidemic	20	38	95	44
Total respiratory disease due to epidemic	106	121	173	122
Ratio of this total to number of uncomplicated influenza deaths	7·6	7·1	7·9	5·5

Comparison with 1918–19 (Table VII.) indicates that the total increase in respiratory disease deaths during epidemics was seven to eight times the increase in uncomplicated influenza deaths, alike in 1918–19 and in the severe waves of 1922, 1927, and 1929, though in 1933 the ratio was lower. A great fall occurred, however, in the proportion of these extra respiratory deaths which were *stated* to be associated with influenza, from 83 per cent. (86 out of 106) in the fourth quarter of 1918 to an average of 45 per cent. in the later epidemics of 1922, 1927, 1929. In 1933, however, the proportion rose to 64 per cent., and it remains doubtful whether this fall represents a change in "fashion" of certification or a real change.

The accusation that the medical profession over-diagnoses influenza during epidemics receives no support from these figures, but it is unnecessary to conclude, either, that it is underdiagnosed, that is to say, that part or all of the extra deaths without mention of influenza did in fact result from a primary or complicating influenzal infection. If influenza is a virus disease and the respiratory complications result from secondary bacterial infections to which the respiratory tract is rendered more susceptible by the virus, presumably the secondary infection may be passed on to others after the virus has ceased to be transmissible, thus leading to contemporaneous waves of pneumococcal or other bacterial respiratory infections amongst persons who have escaped the influenza virus. This might also account for the rise in whooping-cough deaths, as suggested above.

HEART DISEASE AND "OLD AGE"

The graphs in Fig. 2 indicate a definite increase of deaths attributed to heart disease, without mention of influenza as a complicating cause during influenza epidemics, especially when these were severe and the weather cold. Table II. shows an increase from 90 to 110 for January, 84 to 133 for February, and 95 to 112 for March. This is evident, when no account of temperature is taken, for each heart condition in Table II., but separation of the cold from the warm months in Fig. 2 shows that for aortic disease the association with influenza is only apparent, being entirely explained by the consistently higher mortality in the colder months from this cause. The relation of sudden deaths to coldness of the winter months has been pointed out before.[5]

Mitral disease mortality is also affected by temperature, but shows an increase with influenza in the colder months. Table IV. indicates that to each 100 epidemic influenza deaths there were two deaths from mitral disease in excess of expectation during ordinary epidemics and three during the severe waves. Table VI. shows that in the 1933 wave there was an excess of 765 deaths from this cause over the average of the preceding and following quarters, compared with 687 in the six epidemic years between 1921 and 1932, and an average excess of 243 in six normal years, due to seasonal influences. On the basis of the influenzal deaths the anticipated excess of mitral disease deaths would be $243 + (18{,}317 - 1525)\ 444/11{,}435 = 895$, the actual figure being 765. There is no evidence from the Table that the increase during epidemics was followed by any such compensatory deficiency in succeeding quarters as was noticed for phthisis; mortality was enhanced during the half year after the epidemic rather than diminished.

The graphs for fatty heart closely resemble those for mitral disease. Deaths attributed to "myocardial disease" (other than acute myocarditis or fatty heart) have greatly increased in recent years, owing mainly to changes in fashion of certification of the deaths of old people. In 1923 they numbered 13,445 and in 1933 62,009. Satisfactory correction of mortality for this secular trend was therefore difficult, and the ratios in Table II. for this cause must be accepted with reserve, but they appear to show a similar degree of increase during epidemics as do the other heart disease groups. Table IV. shows that to each 100 "epidemic" influenza deaths there were not less than 71 additional deaths attributed to "other diseases of the heart or circulation" during mild or moderate epidemics, or 37 during the severe epidemics.

---

[5] Stocks, P.: Brit. Med. Jour., 1928, ii., 1188; Arteriosclerosis: A Survey of the Problem (E. V. Cowdry, Editor), New York, 1933, p. 212.

Deaths attributed frankly to "old age" without any circumlocution have been steadily declining, but after correction for this secular trend, the mortality figures in Table II. closely resemble those for myocardial degeneration, and the curves in Fig. 2 are similar to those for fatty heart, showing the double effect of coldness and influenza, of which the latter was the more important. According to Table IV., to each 100 epidemic influenza deaths, 6 additional deaths were attributed to old age during ordinary epidemics, or 9 during severe epidemics, and Table V. shows that during the 1933 wave there was an excess of 753 deaths attributed to this cause over expectation from the normal months of 1928 and 1930. The calculated excess was greater than this, but the downward trend since 1928 to the passing out of fashion of this form of statement has not been allowed for in Table V.

OTHER CAUSES

Combining all causes other than influenza and respiratory diseases, mortality was affected to the extent of a rise from 95 per cent. of expectation during the Januaries of lowest influenza to 110 in the Januaries of highest influenza. For February the corresponding indices were 93 to 110, and for March 95 to 105. Fig. 2 indicates that, whereas at a given influenza level coldness was a factor which increased this mortality to some extent, influenza was a more important factor, especially during the colder months. Table V. shows that the anticipated excess of 13,859 deaths from this total group of causes during 1933 epidemic over the same "normal" months in 1928 and 1930 was almost exactly realised.

Diseases of the nervous system, excluding hæmorrhage into the brain, showed a slight rise with influenza, at any rate in the colder months (Fig. 2). Cerebral hæmorrhage, including the deaths attributed to arterio-sclerosis as primary cause, increased more definitely, and it appears from Table IV. that to each 100 epidemic influenza deaths from 7 to 13 additional deaths from cerebral hæmorrhage occurred, the proportion being smaller during the more severe epidemics in contrast to most of the other causes in the Table. The excess of deaths in the 1933 wave, 1333, agreed fairly well with the calculated excess (Table V.). Arterio-sclerosis without cerebral lesion also increased with influenza (Table II.).

Cancer, a disease which was given precedence over influenza when jointly stated with it, manifests no association whatever with either air temperature or influenza prevalence. During January and February, 1933, 10,697 deaths from cancer occurred, and for only 99 of these was influenza mentioned as a complicating cause. (In the fourth quarter of 1918 the proportion was 53 out of 10,633.)

Mortality from nephritis failed to rise consistently with influenza, although January and March deaths from acute nephritis and January and February deaths from the chronic form manifested a slight apparent association with it.

Puerperal sepsis and septicæmia also show, if anything, a negative association with influenza prevalence, and for other puerperal causes there is no consistent change. Premature birth mortality tends to be slightly enhanced during epidemics, as might be expected.

Digestive causes show no association, nor does suicide.

According to Table IV., to each 100 influenza deaths in excess of the normal level, about 180 or 190 additional deaths from all other causes are certified during influenza epidemics, respiratory conditions generally forming a somewhat larger proportion of these during the more severe epidemics, though in 1933 this was not true.

Examination of all the death certificates during January and February, 1933, for the causes usually taking precedence over influenza when jointly mentioned with it (those starred in Table V., syphilitic diseases, scarlet fever, intestinal obstruction, and a few other causes, but excluding suicide or accident) revealed a total of 482 deaths with mention of influenza, or about 1 in 48 of the total deaths from these causes. The total of 482 consisted of 22 whooping-cough, 277 phthisis, 99 cancer, 18 encephalitis lethargica, 17 syphilitic diseases, 10 non-pulmonary tuberculosis, 7 premature birth, 8 intestinal obstruction, 5 puerperal sepsis, and 19 others. It must be remembered that an ordinary attack of influenza more than two or three weeks prior to death from one of these causes would not usually be mentioned on the death certificate, so the above finding could only be taken to mean that about 1 in 48 persons living were attacked on the average in each two or three weeks during the two months, or about 1 in every 12 to 18 during the whole epidemic. The Scottish figures[6] for the insured population show that during the year ending June, 1933, 6 cases of influenza occurred to each 100 persons, which suggests that between 1 in 10 and 1 in 20 persons were attacked during the epidemic. The incidence rate recorded for the army in the United Kingdom in 1933, was 1 in 25. The prevalence suggested by death certification is therefore in reasonable agreement with such measures of the actual incidence as are available.

Summary and Conclusion

During the influenza epidemics of 1921–33, which occurred mainly in the first quarter of the year, monthly mortality certified as due to many other causes, without mention of influenza as a primary or contributory cause of death, increased step by step with the severity of the influenza mortality. The causes most remarkably affected were whooping-cough, acute bronchitis, broncho-pneumonia, chronic bronchitis, asthma, pneumonia not defined, lobar pneumonia, and pulmonary tuberculosis, but mitral disease, fatty heart, myocardial degeneration, old age, cerebral hæmorrhage, arterio-sclerosis, nervous diseases, and premature birth also showed pronounced increase of deaths during epidemics.

During moderate epidemics each 100 influenza deaths, so described, in excess of the number occurring during the same months in interepidemic periods, included 73 with respiratory complications, and was accompanied by 190 other deaths in excess of expectation, consisting of 80 from respiratory diseases (without mention of influenza), 13 from cerebral hæmorrhage, 7 from whooping-cough, 6 from "old age," 5 from pulmonary tuberculosis, 2 from mitral disease, 71 from other diseases of the heart and circulation, and 6 from other conditions. During severe epidemics each 100 influenza deaths was usually accompanied by rather more than the above proportion of deaths from the respiratory causes, offset by less from circulatory causes.

Whooping-cough showed the most phenomenal rise of mortality with influenza in proportion to its numerical importance as a cause of death, and it is suggested that either the double infection must be very fatal, and must generally pass unrecognised as such, or else the increased mortality must be due to the secondary respiratory infections being transmitted from influenza to whooping-cough patients.

---

[6] Report on Incapacitating Sickness in the Insured Population of Scotland, 1932–33, Table V.

It is also suggested that the great increase in deaths from bronchitis and pneumonia (without mention of influenza) during epidemics need not indicate lack of precision in diagnosis, but may indicate contemporary waves of the secondary infections of the respiratory tract started by persons originally infected by the influenza virus. The heavy phthisis mortality was partly attributable to hastening of inevitable death from that cause, and to that extent was offset by diminished deaths in the latter half of the year.

There was no clear evidence of increase of infections of other parts of the body, and the large increase in deaths attributed to non-respiratory causes during influenza waves seems to require either (1) that there is a lowered state of resistance to many disorders at the time when the epidemics occur, or (2) that influenza as a cause of death is very often not diagnosed owing to the medical attendant not having been consulted in the early stages of illness but only when sequelæ have developed, or (3) that influenza though recognised as the initial cause is not mentioned as such on the death certificate.

After giving full weight to the possible alternative explanations, there can be no doubt that incomplete medical certification is partly responsible for the widespread diffusion of the increase in mortality during influenza epidemics over the list of causes, and particularly for the great increase in deaths ascribed to myocardial disease and old age. It was hoped that the introduction of a new form of certificate in 1927 would result after a short interval in a very definite improvement in the reliability of medical certification, but whilst this hope has been fulfilled in certain respects it has not yet been realised to the desired extent in other directions, especially with regard to the manner of statement of joint causes of death.

The writing of a satisfactory death record is often a matter of no small difficulty, and it is to be regretted that the representations made some six years ago that adequate instruction should be given to every medical student in the matter of death certification have not yet met with a wider response in the teaching schools. A considerable service can be rendered to the preventive medicine of the present and of the future by each physician, surgeon, or pathologist who endeavours to produce accurate and complete mortality and notification records, and time can surely be found even in an overloaded curriculum to impress this fact upon every student before training is completed.

MEDICINE AND THE LAW

Omission to Notify Infectious Disease

A DOCTOR was fined sums amounting (with costs) to £6 5s. at Daventry last month for failure to notify cases of infectious disease. The alleged offences related to dates in March, April, and June, and the solicitor who prosecuted on behalf of the rural district council stated that on Jan. 10th the doctor's attention was called to the necessity of notification. The medical officer of health gave evidence that no certificates had been received in respect of three scarlet fever patients, a certificate for a girl suffering from diphtheria was not received until after she had recovered and left hospital, and in another scarlet fever case, admitted to hospital on June 1st, notification was not received till June 18th. The doctor pleaded guilty. In extenuation it was said that he had been overworked at the time and that three of the cases came from households where previous cases of infectious disease had already been notified. It was suggested that in some districts it is the practice to regard the notification of a single case from a particular family or home as covering subsequent cases from the same family or home. The Public Health Acts give no support to such a practice.

Alleged Attempt to Commit Suicide by Starvation

At Blackpool police-court last week Mr. Davidson, the former rector of Stiffkey, was charged with unlawfully fasting "with intent feloniously, wilfully and of his malice aforethought, to kill and murder himself." Apparently the accused was exhibited in a cubicle at a wax-works exhibition with posters which described him as intending to starve himself to death if an adverse decision of the ecclesiastical court were not reversed and if he were not reinstated by the bishop. A police officer said that the accused was so weak after a fast of ten days that he had to be lifted out of the case. It was contended on behalf of the defendant that there was no evidence that in this ten-day period he had been in any danger of death. The magistrates thought there was a case to answer and committed him for trial at Preston quarter sessions, bail being allowed on the defendant undertaking that meanwhile he would not starve, pretend to starve, or exhibit himself in a cabinet.

The law against attempted suicide is variously enforced. There have been official announcements that in many cases the police take no action unless it is necessary in the interests of the accused. The "hunger-strike," undertaken for political motives or otherwise, has no immunity from prosecution. The motive of attempted suicide is immaterial.

IRELAND

(FROM OUR OWN CORRESPONDENT)

SWEEPSTAKE MONEYS

IN answer to a question addressed to him in the Dáil the Minister for Local Government and Public Health has given some interesting information about the money which has been distributed to the hospitals of the Irish Free State from sweepstakes funds and the money which awaits distribution. He states that there is at present in the hands of the National Hospital Trustees a sum of £4,050,778, to which is to be added approximately £354,835 derived from the sweepstake on the Derby of this year, not yet paid over. Beside these sums the Minister has in his own hands for distribution £433,177 obtained from sweepstakes held before the passing of the Hospitals Act, 1933. So far sums amounting to £3,703,080 have been distributed to the hospitals under various Acts. He added that a preliminary report has been submitted by the Hospitals Commission and is under consideration. There has been, and will be, no avoidable delay in carrying out the intentions of the Public Hospitals Act, 1933, but obviously the matter is one of such magnitude that its investigation will take time.

THE LATE DR. C. M. O'BRIEN

Dr. Christopher Michael O'Brien, who died in Dublin on August 5th, qualified from the Royal Colleges of Ireland in 1892 and 1893, and graduated as M.D. Durh. in 1900. Early in his professional career he became interested in dermatology, and was the first medical man in Ireland to practise that branch of medicine as an exclusive specialty. He founded the Skin and Cancer Hospital in Dublin while he was *still* a young man, and continued to conduct it up to the time of his final illness. He was one of the first in these countries to apply radium to the treatment of disease. A kindly and generous man he was held in much esteem by his friends and patients.

VIENNA

(FROM OUR OWN CORRESPONDENT)

REFORM OF THE MEDICAL CURRICULUM

THE reforms which the present authoritarian government is introducing into every branch of public life have now been extended to the universities, where the following new regulations will come into force next session. Each academic year is to consist of two semesters (or terms), the winter semester lasting from Oct. 1st to Jan. 31st and the summer semester from Feb. 15th to June 28th. Thus both terms will be of about the same length, whereas under the present system the winter term has been five months and the summer term only three months. The dates given mark the commencement of lectures for students. The Christmas vacation will be from Dec. 19th to Jan. 7th and the Easter one from March 16th to April 20th. Examinations and graduations (called here "promotions") will be held if necessary all the year round, except during the Christmas vacation and the summer vacation (July 15th to Sept. 20th) when all the universities will be closed. During these "free weeks" the students will be expected to take part in "university camping," which is a mild form of military training. Regulations for these exercises will be published shortly. Various special regulations are also made for the maintenance of hospital and ambulance services and of scientific work during the vacations.

Changes have also been made in the existing rules governing medical examinations, which have been in force since 1903. Medical students must henceforward pass three groups of examinations, each of which is termed a *Rigorosum*. The first rigorosum is passed in the fifth semester, and consists of natural science (physics), chemistry, physiology, histology, and anatomy. There will be theoretical (viva voce) and practical examinations in all the subjects except natural science, in which the examination will be purely theoretical. Biology has been dropped, and students who have already taken the first rigorosum but have failed in biology will not be required to sit again in that subject. The second rigorosum will consist of examinations in morbid anatomy and histology, pharmacology and dispensing, materia medica, pædiatrics, neurology, and psychology. Candidates will be examined theoretically and practically in all subjects except pharmacology and dispensing, for which only a theoretical examination is required. General and experimental pathology, which was formerly also included in the second rigorosum, has been dropped. The third rigorosum, taken after the eleventh semester, embraces all the other subjects of the medical curriculum (surgery, including orthopædics; obstetrics and gynæcology; ophthalmology; oto-rhino-laryngology; dermato-syphilology; hygiene and forensic medicine).

A novel feature in the new regulations is the clauses directed against unsuccessful candidates. Under the old regulations a candidate who failed in part of the first rigorosum was allowed to take the examination again several times if necessary. Now he is only allowed three attempts if he fails in one subject, and two if he fails in two or three subjects. Should he fail in four subjects he will not be allowed to continue the study of medicine in this country, nor may he later apply for registration in Austria on the strength of a foreign medical qualification. A candidate who has been unable to finish his first rigorosum within two years of first presenting himself for the examination will also be permanently excluded from medical study in Austria. Exceptions will naturally be made where the candidate is not responsible for the delay (illness, war). A candidate who has successfully passed all three examinations must apply within six weeks for "promotion" to the degree of "doctor universæ medicinæ." Otherwise he runs the risk of losing his turn and may have to wait for months before he is called up.

The idea of eliminating the less successful students during the course of their medical studies is by no means unreasonable. Its aim, of course, is to prevent students from embarking on a career for which they are not suited. The necessity of finishing their studies within a limited time will encourage undergraduates to concentrate on their work, and the majority of the profession approve of the new rule. The *sine qua non* is that the examiners deal fairly with the candidates, and this is certainly to be expected in Austria.

BIRTH-RATE AND INFANT MORTALITY

Changes in the population have shown the same trend during recent years in all the countries involved in the late war. After 1918 the birth-rate went up, only to fall again a few years later. In Austria in 1920 there were 137,372 live births, in 1921 there were 141,834 (an increase of over 3 per cent.), and in 1922 there were 150,958 (an increase of 7 per cent.). But that was the peak year, and the following Table for the next ten years shows a decrease of 40 per cent.:

Year.	Live births.	Year.	Live births.
1923	146,633	1929	110,171
1925	135,594	1932	102,254
1927	118,302	1934	90,934

Some countries have attempted organised measures to increase their birth-rates (premiums to families with numerous children), but here we have only one scheme of this kind: a premium of 120 Austrian shillings (£4 10*s.*) is paid for a live birth to mothers insured under the new Social Insurance Act. Attempts to bring down the infant mortality have however given satisfactory results. In 1920 it stood at 157 deaths per 1000 live births; next year it dropped to 154; and since then it has constantly decreased, as is seen from the following Table of mortality among infants up to twelve months old:

Year.	Total deaths.	Deaths per 1000 live births.	Year.	Total deaths.	Deaths per 1000 live births.
1923 ..	20,653	141	1930 ..	11,665	106
1925 ..	15,895	117	1932 ..	10,888	106
1928 ..	13,964	120	1934 ..	8,821	91

The rapid drop in the total number of deaths is of course due to the decrease in the birth-rate, but the drop from 141 to 91 deaths per 1000 births is undoubtedly satisfactory. The decrease is due to the work done by the executive committee for infant welfare instituted by the ministry for social welfare and public health. They began with 104 clinics which gave advice to mothers. A special scientific committee composed of the leading pædiatricians, directors of the local boards of health, and officers of the ministry investigated the problems of protection of mothers and infants against disease, and laid down general principles for the guidance of the clinics. It also assisted the local authorities in organising similar clinics all over the country, so that now we have 492 advisory centres with 78 branches and 13 antenatal clinics scattered over Austria. A staff of 515 doctors and 530 trained nurses is employed, and the expenditure for 1934 was 773,000 shillings (£30,000) and an attendance of 47,286 infants under eight months and 56,112 over eight months is recorded.

PANEL AND CONTRACT PRACTICE

The New Insurance Act Explained

JUST before Parliament rose Royal Assent was given to the National Health Insurance and Contributory Pensions Act, 1935, and on the same evening the Minister of Health broadcast an explanation of the chief features of the Act. It may be well briefly to recapitulate the principal provisions which affect the medical profession.

On ceasing to be insurably employed all insured persons are to have a free insurance period on an average of 21 months. During this period insured persons are to be protected for all pensions purposes and entitled to all health insurance benefits—medical, sickness and disablement, maternity, and additional benefits. If at the end of the free period an insured person who has been continuously insured for ten years, up to the date when he ceased work, proves that throughout the period he (or she) has been unable to obtain insurable work his insurance will be extended so long as unemployment continues to be proved year by year. During these periods of extended insurance he will be covered for all pensions rights and be entitled to medical, maternity, and additional treatment benefits, and will remain a member of his approved society. He will not be entitled to sickness and disablement benefit, but he can regain title to these benefits at the full rates if he again obtains insurable employment, although of course not immediately.

Under the Act of 1932 many insured persons have already ceased to be entitled to medical benefit and but for the passing of the new Act would have lost their pension rights at the end of 1935. These persons will be subjected to the ten years' test, but for the great majority of them the test will be applied at a much later date than that on which they ceased to be employed. If they satisfy the test they will be maintained in insurance so long as they continue to prove unemployment and, as from Jan. 1st, 1936, will be restored to medical, maternity, and additional treatment benefits and their pension rights will continue. Insurance doctors, especially those in the depressed areas, will thus have restored to their lists many of the insured persons removed under the 1932 axe. As from July, 1934, all arrears due to proved unemployment are to be excused in full; half the cost will be met by a levy on each contribution paid by members of approved societies and the other half by an annual Exchequer grant.

Hitherto deposit contributors have ceased to be entitled to medical benefit when their individual credit in the deposit contributors' fund becomes exhausted. In future, arrangements will be made to provide medical benefit for life to deposit contributors who are entitled to the benefit on reaching the age of 65, and they will thus be treated, for medical benefit, similarly to members of approved societies attaining that age.

Another anomaly which will be removed is in respect of a woman aged over 65 who marries. In the past such a woman, who otherwise would have been entitled to medical benefit for life, upon marriage was treated as having become a "Class K" member, and lost her title to medical benefit in about eighteen months.

Assistance at a Vaginal Operation

A west-country insurance practitioner assisted at an operation on one of his patients in which the cervix uteri was amputated and the vagina narrowed by stitches fore and aft. The insurance and local medical committees were in agreement that this assistance was of a specialist nature and that the doctor had the necessary skill and experience for its performance, but the Minister thought that it came within the doctor's terms of service and ordered an inquiry. On behalf of the two committees it was urged that the assistant at such an operation might be called upon to arrest a sudden hæmorrhage, or to hold the artery forceps or retractors in such a way as to enable the surgeon to get a clear view of the field of operation, and that many surgeons would prefer the ward sister as an assistant because of her greater familiarity with the task. It was further suggested that after years of absence from operating theatres some practitioners would not possess experience of modern operative procedure. A questionnaire had been sent to the 154 practitioners on the insurance committee's list to which 106 had replied, 48 of them being surgeons on the staff of their local hospital. Eight of these surgeons said they would be prepared to accept as an assistant at a major operation every insurance practitioner in the area from which his surgical cases were derived; the other 40 would not. Of the 58 other doctors who replied 25 would be prepared to act as assistant at a major operation—8 of them habitually act as such at all major operations performed on their insured patients; 33 would not be prepared to act; and 50 do not act as assistant at major operations.

The referees report that they are satisfied that the treatment in question did not involve the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess. They add that the fact that 40 of the 48 surgeons on the staff of their local hospital who replied to the questionnaire were not prepared to accept as an assistant *every* panel practitioner in their area is in their view irrelevant to the inquiry. The issue was whether general practitioners as a class can reasonably be expected to possess the necessary skill and experience, not whether every general practitioner possesses it or is thought by his fellow practitioners to possess it. The fact that 33 of the 154 doctors to whom the questionnaire was sent said they would not be prepared to act as assistant at a major operation was too vague without knowing what operation they had in mind. The reason why so few habitually did act as assistants at all major operations appeared to be because the hospital where the operation occurred was frequently outside their area.

While it must be remembered that the decision relates only to the particular case the observations can well be applied as a general principle.

A Remitted Penalty

A month or two ago (see THE LANCET, May 11th, p. 1129) the London local medical and panel committee investigated a complaint that a doctor had secured the transfer to his list of a patient of another doctor without the knowledge or consent of the insured person. The complaint having been found to be established it was necessary, under existing rules, for the committee to inform the Minister that the continuance of the doctor on the Medical List would be prejudicial to the service. Subsequently, however, it was felt that in the event of the Minister confirming the finding of the committee the penalty of removal from the list would be excessive. Only one such misdemeanour was alleged, and the complainant wanted to withdraw his representation provided the respondent sent a suitably worded undertaking not to offend similarly again. The respondent having now written expressing regret, and undertaking that there shall be no recurrence of the offence, the committee have decided (subject to a verbal amendment of the letter) to comply with the complainant's request.

It may be recalled that, after an investigation by its medical service subcommittee into any question relating to the conduct of a practitioner, an insurance committee may take action in any one or more of the following ways:—

(1) If they are satisfied that owing to the number of persons included in his list the practitioner is unable to give adequate treatment to all those persons, they may, after consultation with the panel committee, impose a special limit on the number of persons he may have included in his list.

(2) They may recover from him any expenses (other than those incurred in connexion with the medical service subcommittee's investigation) which have been reasonably and necessarily incurred by the committee or by an insured person or his representative owing to the practitioner's failure or neglect to comply with the terms of service.

(3) They may recommend the withholding of money.

(4) They may make representations for the removal of the practitioner's name from the medical list.

But it not infrequently happens that a practitioner is found to have committed an error of omission or of commission which is hardly of such a nature as to merit action under any of these four heads. It has become the custom for insurance committees in such cases either to warn the doctor of the necessity for a strict compliance with his terms of service, to caution him or to censure him. But it must be admitted that a censure is usually associated with action under (2) or (3) or both.

A Suspended Report and its Sequel

Committees are generally believed to have less compassion than their individual members. The recent action of a provincial medical benefit subcommittee reveals a very human touch; the pity of it is that the endeavours of the committee to help a doctor did not meet with success. In February last the committee investigated two complaints of failure to visit two persons on his list when requested to do so. The doctor admitted the failure which he ascribed to illness; he was, he said, undergoing a course of special treatment which would last five months. The committee decided to defer submitting their report on these two cases for six months conditionally upon the doctor undertaking to furnish at monthly intervals certificates (1) from the specialist providing the treatment that the doctor was following his directions (2) from a colleague that he was diligently carrying out his duties as an insurance practitioner. Article 33 (4) of the *Regulations* requires a medical service subcommittee to draw up a report and to present it to the insurance committee, but it does not specify when the report is to be presented, and there was nothing irregular in keeping the report in suspense to see how things turned out. Unfortunately the doctor failed to furnish the certificates required and it became necessary for the subcommittee to report that he had absented himself from his practice for longer than a week without first informing the committee as required by Clause 11 (2) of the Terms of Service, and to make a recommendation as to the action to be taken. The doctor then asked for leave to withdraw his name from the Medical List, and this was granted subject to an undertaking (which was given) that he would not, without the Minister's consent, engage in insurance practice as a principal.

PUBLIC HEALTH

Gas Heating of Flueless Rooms

THE tendency for houses to be built with some of the rooms unprovided with chimneys no doubt makes for economy in building—a matter of importance in these days when the costs of building are so high. The advisability, from a health point of view, of this practice is however a serious question which is so far from having been settled that the governor of the largest gas company in the world has induced the Royal College of Physicians to refer it to a committee of physiologists and public health experts. The conclusions so far reached by this committee have been made public, pending a final report. They refer only to conditions in dwelling-houses and not to those in factories and workshops.

At the outset the committee are faced with the fact that the rate of exchange of air in a room ventilated only by imperfectly fitting doors and windows, with or without the occasional air brick, is not really known with any precision; it is surmised that the air of such a room may be renewed from once in two hours to once in an hour, but whether this estimate is approximately correct, or whether even the higher rate presumed is sufficient to keep the room in a healthy and comfortable condition is not known. It is hoped by the committee that experimental work may be arranged on this point. With unventilated rooms the escape of heated air and the entry of cool air, which in cold weather needs to be heated, will be relatively small and therefore the amount of heating will be proportionately less than in rooms with chimneys or open windows; but the use in any room of flueless gas heaters, which discharge all the sensible heat and also all the products of combustion into the room itself, needs closer consideration when the ventilation is not very efficient.

Of the products of combustion of coal-gas water vapour may in some cases be beneficial in raising the humidity of dry air; it may be harmful if the air is already very humid. Carbon dioxide is harmless in any concentration likely to occur; carbon monoxide is not found in appreciable amounts in the gases from well-designed appliances kept in good condition. The only products likely in the opinion of the committee to be harmful in themselves are the oxides of sulphur and of nitrogen, the former derived from combustion of sulphur in the gas, the latter always found when air is heated sufficiently for oxygen and nitrogen to combine. A trained nose will usually detect the higher oxides of nitrogen in the air of a room overheated and underventilated when gas is the fuel (incidentally it may be mentioned that the same thing must occur with many electric heaters); the oxides of sulphur are less apparent, but sulphur trioxide probably accounts for the acrid dry smell of such rooms. Sulphur dioxide, which is the first product of combustion of sulphur, is just detectable when its concentration reaches 2 parts per million (volumes), and may be harmful if 10 parts are present, although this is uncertain.

The committee conclude that discomfort from overheating would be experienced before harmful concentrations of sulphur and nitrogen oxides were reached and the gas would be turned out or lowered. This conclusion seems to be based on sound common sense. The effect on metal work in rooms where the products of combustion are freely diffused was not within the committee's reference. It would probably be considerable.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 3RD, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1664; diphtheria, 883; enteric fever, 61; acute pneumonia (primary or influenzal), 436; puerperal fever, 36; puerperal pyrexia, 104; cerebro-spinal fever, 22; acute poliomyelitis, 30; polio-encephalitis, 1; encephalitis lethargica, 4; dysentery, 20; ophthalmia neonatorum, 114. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 9th was 2653, which included: Scarlet fever, 776; diphtheria, 958; measles, 32; whooping-cough, 426; puerperal fever, 23 mothers (plus 5 babies); encephalitis lethargica, 269; poliomyelitis, 7. At St. Margaret's Hospital there were 22 babies (plus 11 mothers) with ophthalmic neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever. 10 (0) from measles, 6 (2) from scarlet fever, 11 (2), from whooping-cough, 27 (2) from diphtheria, 56 (10) from diarrhœa and enteritis under two years, and 5 (0) from influenza. The figures in parentheses are those for London itself.

The deaths from diarrhœa and enteritis are little more than last week, the highest numbers being Birmingham 8, Liverpool 7, Manchester 5, no other great town more than 2. Of the 9 fatal cases of whooping-cough outside London 2 occurred at Birmingham; the others were widely scattered. Liverpool reported 4 deaths from measles, Sunderland 2. No great town reported more than 2 deaths from diphtheria.

The number of stillbirths notified during the week was 248 (corresponding to a rate of 36 per 1000 total births), including 30 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. K. H. Hole, O.B.E., to *Drake* for R.N.B.

Surg. Comdr. C. H. Savory to *Pembroke* for R.N.B.

Surg. Lt. D. W. Pratt to *Weston* and G. D. Wedd to *Victory* for Haslar Hospital.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. A. S. Pearson to *Victory* for R.N.B.

Surg. Sub-Lt. D. Shute to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Maj. H. G. Hobson, O.B.E., M.C., retires on ret. pay.

REGULAR ARMY RESERVE OF OFFICERS

The undermentioned having attained the age limit of liability to recall, cease to belong to the Res. of Off.: Lt.-Col. R. J. C. Thompson, C.M.G., D.S.O., and Majs. A. W. Howlett and H. T. Stack, O.B.E.

Capt. H. L. Oldershaw resigns his commn.

ROYAL AIR FORCE

Flight Lt. F. W. P. Dixon, M.B.E., to R.A.F. Depôt, Uxbridge; R. G. Freeman to R.A.F. Hospital, Cranwell; and H. J. Melville to R.A.F. Station, Boscombe Down.

Flight Lt. G. E. Church is promoted to the rank of Squadron Leader.

Dental Branch.—Flight Lts. W. D. Guyler to R.A.F. Depôt, Uxbridge, and B. L. Harrington to Home Aircraft Depôt, Henlow.

INDIAN MEDICAL SERVICE

Capt. E. G. Hurd-Wood to be Maj. (provl.).

Lts. (on prob.) to be Capts. (on prob.): J. Brebner, W. J. Virgin, H. W. G. Staunton, J. D. Gray, D. W. Taylor, P. H. Addison, C. U. Wickham (since decd.), March 11th, 1935, with seniority Oct. 25th, 1934; S. G. O'Neill, F. J. Doherty, J. W. D. Goodall, and C. B. Miller.

The undermentioned officers retire: Lt.-Cols. A. N. Thomas, D.S.O., H. W. Acton, C.I.E., and A. P. G. Lorimer (on account of ill-health).

Capt. K. C. Virmani relinquishes his temp. commn.

The undermentioned officer has vacated appt. in India:—

D.A.D.M.S.—Lt.-Col. P. S. Tomlinson, M.C., R.A.M.C., and has been appointed as Deputy Director of Medical Organisation for War.

The undermentioned appts. have been made in India:—

D.A.D.M.S.—Lt.-Col. G. F. Allison, M.C., R.A.M.C.

D.A.D.P.—Maj. C. Scales, R.A.M.C.

COLONIAL MEDICAL SERVICE

Dr. A. C. de B. Helme has been appointed Medical Officer, Tanganyika, and Dr. D. E. C. Mekie, Medical Officer, Malaya. Dr. H. P. Fowler becomes Senior Health Officer, Gold Coast; Dr. P. E. M. Lanier, Senior Medical Officer, Seychelles; and Dr. S. M. Vassallo, Senior Specialist Officer, Zanzibar.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The next series of post-graduate courses will begin in September: heart and lung diseases at the Royal Chest Hospital (Mondays, Wednesdays, and Fridays, 8 P.M., from Sept. 9th to 27th); pathological and clinical demonstration at the National Temperance Hospital (8 P.M., Tuesdays and Thursdays, Sept. 10th to 26th); infants' diseases at the Infants Hospital (Sept. 2nd to 13th); medicine, surgery, and the specialties at the Westminster Hospital (Sept. 16th to 28th); chest diseases at the Brompton Hospital (Sept. 23rd to 28th), and ophthalmology at the Royal Westminster Ophthalmic Hospital (Sept. 28th and 29th). The courses at the Royal Chest and National Temperance Hospitals are primarily, but not exclusively, intended for candidates for the M.R.C.P. examination. Other forthcoming courses include: anatomy and physiology (primary F.R.C.S.) at the Infants Hospital (8 P.M., on Mondays, Wednesdays, and Fridays, from Oct. 7th to Nov. 29th); endocrinology at the National Temperance Hospital (8.30 P.M., on Tuesdays and Thursdays from Oct. 8th to 24th); and gynæcology at the Medical Society of London (4 P.M., on Thursdays from Oct. 10th to Nov. 7th). Detailed syllabuses of all courses can be obtained from the secretary of the Fellowship, 1, Wimpole-street, London, W.1, within a few weeks of the starting date of each course. Courses of instruction, arranged by the Fellowship, are open only to members and associates.

OBITUARY

SIR JAMES PORTER, M.D. Aberd., K.C.B., K.C.M.G.

LATE DIRECTOR-GENERAL, MEDICAL DEPARTMENT, R.N.

WE regret to announce the death on Friday, August 9th, of Surg. Vice-Admiral Sir James Porter, a distinguished former director-general of the medical department of the Royal Navy. The event occurred at St. John's Lodge, Wakefield, at the age of 83.

James Porter was born in 1851 and educated at the Old Grammar School, Aberdeen, and the University of Aberdeen, where he graduated in arts in 1874 and in medicine three years later. Immediately on medical qualification he entered the medical service of the Royal Navy. He was first appointed in 1877 to the Mediterranean fleet, but later joined the troopship, *Orontes*, in which he served throughout the Egyptian war of 1882, obtaining the medal and Khedive's Star. In 1884 and 1885, on duty with the Royal Marine Battalion sent to the Sudan, he was present at the action of Tofrek (March 22nd, 1885) and received two clasps to his Egyptian decoration for services during the campaign. Following a year's home service in Chatham he proceeded to Bermuda in medical charge of the Naval Hospital, and in 1889 was appointed to the depôt ship at Portsmouth, at which time he was promoted staff surgeon. After a period of service in the Mediterranean he returned to Bermuda, holding now the position of medical officer to the dockyard there; at the expiration of this appointment he became senior medical officer of the *Britannia* at Dartmouth. Here Porter in his relations with the cadets earned an enviable reputation both for ability and for the helpful and kindly attitude displayed towards his young charges; at the expiration of his time on the *Britannia* he was promoted fleet surgeon. In 1889 occurred the South African war, and Porter saw much service as fleet surgeon with the Naval Brigade, was mentioned in dispatches, obtained the Queen's medal with eight clasps, and was specially promoted to the then existing position of Deputy Inspector-General of Hospitals and Fleets.

[*Photograph by Elliott & Fry*

SIR JAMES PORTER

The record of his service becomes now one of steady well-merited success. In 1901 he went to Haslar as second in charge; in the following year he was in charge of the Royal Hospital at Chatham, when he received the C.B.; and in 1905 he held the same appointment at Gibraltar; he was promoted Inspector-General in 1906, becoming two years later the head of his branch of the profession as Medical Director-General of the Navy with the rank of Vice-Admiral. In 1910 he received the K.C.B., and the year before the European war had retired from the active list, but on the declaration of hostilities he returned to the Navy for special duties at the Admiralty arising out of his long and practical experience in the working of the naval medical service. During the European war he served as principal hospital transport officer in the Mediterranean and the Dardanelles, and in 1916 was appointed K.C.M.G., having also received the Star and Allies medal and the Victory medal. This is the brief story of a distinguished national servant.

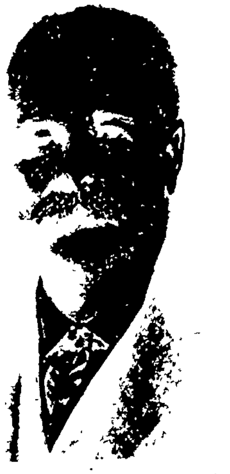
At different times in his career the quality of Porter's work was recognised without the limits of his particular service. He was honorary physician to the King, and a Knight of Grace of the Order of St. John of Jerusalem; his own university and the University of Edinburgh made him a LL.D., and he held the Coronation medal. He married in 1886 Emma, daughter of the late Inspector-General M. W. Cowan, R.N., by whom he had one daughter. He had been a widower for three years. He will be buried at sea.

WILLIAM THOMAS HOLMES SPICER, M.B. Camb., F.R.C.S.Eng.

CONSULTING OPHTHALMOLOGICAL SURGEON, ST. BARTHOLOMEW'S HOSPITAL

THE death occurred on August 8th at his house in Wimbledon of Mr. Holmes Spicer, the ophthalmologist, as well-known as an organiser and an authority on the teaching of his science as he was as clinical exponent. He was in his seventy-fifth year.

Holmes Spicer was born at Saffron Walden and educated at the school there, and later at Barnet, whence he proceeded to Cambridge. At first attached to no college, in 1879 he entered Gonville and Caius, and graduated in 1880 with honours in the Natural Science Tripos. He proceeded for his medical education to St. Bartholomew's Hospital, took the diploma of M.R.C.S. in 1884, the Cambridge M.B. in 1886, and the F.R.C.S. Eng. in 1888. At St. Bartholomew's he had a prominent career, being Bentley surgical prizeman and later Brackenbury surgical scholar. He was house surgeon and ophthalmic house surgeon to the hospital, and followed many distinguished predecessors in being president of the Abernethian.



[*Photograph by Lafayette*

MR. HOLMES SPICER

After a short period of general practice he decided to follow the specialism in which he created for himself a successful position. Following a clinical assistancy at Moorfields he was appointed ophthalmic surgeon to the Metropolitan Hospital and to the Victoria Hospital for Children, and did noticeable work at the latter institution in connexion with scurvy rickets, making communications on the subject to the Transactions of the Ophthalmological Society. In 1898 he was appointed surgeon to Moorfields, a position which he occupied for over 20 years; he was for a long period dean at the hospital, a post which he filled to admiration, the number of students mounting up as the organisation of the teaching, through Spicer and the staff, became perfected. In 1901 Bowater Vernon retired from his position as ophthalmic surgeon to St. Bartholomew's, and Walter Jessop succeeded him with Holmes Spicer as his junior colleague. Spicer was on the staff at St. Bartholomew's until 1920, when he retired under the age rule, but was appointed a governor of the institution and a member of the house committee in recognition of his valuable coöperation.

Spicer was a considerable author throughout the whole period of his hospital appointments, although he wrote no standard work on ophthalmology. He regularly contributed to the Transactions of the Ophthalmological Society, his articles covering a very large clinical area and displaying both physiological and practical wisdom. He wrote the article on the cornea in the Encyclopædia Medica, contributed to Posey and Wright's "Diseases of the Eye, Nose, Throat, and Ear," and edited the sixth edition of "Diseases of the Eye," by Nettleship, whom he had worked under and had succeeded at Moorfields. This edition appeared seven years after its predecessor. The original work dealt with the more common forms of ophthalmic disease and their characteristic symptoms, and laid down the broad principles of treatment, so that much revision might not be considered necessary, but Spicer greatly improved the work. In its new form descriptions of operations were simplified, statements not sanctioned by more mature experience were omitted, and new facts were added, making of the sixth edition of Nettleship's valuable manual a work thoroughly representing the state of ophthalmic knowledge at the day.

Spicer, who was twice married, leaves no children. In his leisure time, both while in practice and after retirement, Spicer painted, mainly in water-colour, and many may have seen his drawings privately or at exhibitions at the Royal Society of Medicine of work by medical artists. The portrait is reproduced from a photograph taken on his retirement from St. Bartholomew's.

Sir John Parsons writes: "The death of Mr. Holmes Spicer has bereft ophthalmologists of an esteemed colleague and a loyal friend. He brought to his work a sound knowledge of general science, acquired at that best of scientific schools, Cambridge; but in addition he was widely read in literature and history, and endowed with unusual artistic ability and outlook. Coming early under the influence of the most scientific teacher of his time, Edward Nettleship, any high flights of imagination and originality, of which he was fully capable, were coördinated and controlled by that stern but salutary taskmaster. With his gift of accurate draughtsmanship it was natural that his notes of cases should be profusely illustrated by sketches of abnormal conditions, often revealing to others the true nature of a case in a manner which verbal description alone failed to convey. He was specially interested in the innumerable types of corneal ulcer and opacity; and his Gifford Edmonds Prize Essay on 'Parenchymatous Keratitis,' &c., published as a monograph by the *British Journal of Ophthalmology*, embodied the work of a lifetime. It is enriched by many exquisite drawings and will ever remain a classical contribution to the subject. On holidays and in retirement he gave free rein to his artistic bent, revelling in the beauties of scenery and architecture, perpetuating many scenes with no mean skill. One such sketch, which he gave to me, has been highly praised by competent critics, and there is little doubt that, had he devoted his life to art, he would have attained a high position—but that would have been at the expense of his outstanding contributions to ophthalmology. It is difficult for one who is proud to claim the title of a friend to convey the charm of Spicer's personality. Of massive build and sedate demeanour, always unperturbed and somewhat slow of speech, he was full of kindliness and humour. It was a unique experience to travel abroad with him and witness his enjoyment of everything—including the 'good things' of life."

J. T. writes: "One who had been on terms of cordial and intimate friendship with him for more than 40 years may be permitted to add a few words to your tribute to Holmes Spicer. He was a big man physically, slow in his movements, but mentally very alert, with a quickness of observation which surprised one. It was a special pleasure to be on holiday with Spicer. The writer can look back on happy times in France, Italy, and Sicily with him and on many week-ends at Rye. The memory of these times is a very happy possession, and one can never forget the helpful and sympathetic care with which he conveyed back to London the friend suddenly seized with illness on one of those week-ends. Spicer's artistic gifts were much in evidence. His water-colours were his great pleasure, but in the writer's opinion his pencil sketches were even better, although he himself revelled in colours. He was very fond of music, and in early days singing was a pleasure to him and gave much pleasure to others. He was at his best among a few intimate friends when his genial presence, his keen sense of humour, and his inimitable reproduction of patients' tales combined to render an evening memorable."

WALTER GIFFORD NASH, F.R.C.S. Eng.

CONSULTING SURGEON, BEDFORD COUNTY HOSPITAL

THE death occurred on Friday, August 2nd, of Mr. Gifford Nash, one of the best-known provincial surgeons in the country and rightly recognised as a pioneer in more than one important direction of surgery.

Walter Gifford Nash was born in 1862 at the parsonage, Berden, Essex, the fourth son of the Rev. Frederick Gifford Nash. He was educated at the Gloucester Cathedral, and went for his professional education to the Middlesex Hospital, entering the medical school in 1882 with an entrance scholarship and other exhibitions. He took the English double qualifications in 1887, served as house physician, as house surgeon (under Henry Morris), and as obstetric house physician to the hospital, and in 1891, having been for a period house surgeon to the South Devon and East Cornwall Hospital, Plymouth, he obtained the F.R.C.S. Eng. In 1891 he went into practice in Bedford, much of his excellent work later being done in connexion with his appointment as surgeon to the Bedford County Hospital, although already he had made a mark by the original nature of contributions to this journal and elsewhere.

We owe to Mr. G. Gordon-Taylor the following summary of Gifford Nash's surgical career:—

"The death of Walter Gifford Nash has not only robbed Bedford and Bedfordshire of a great surgeon and a charming personality, but British surgery is also the poorer for the loss of one who made notable contributions towards its advancement. It was always difficult to realise in conversation or in coöperation with Gifford Nash that he had been practising for nearly half a century, and that his earliest contribution to the columns of THE LANCET was made as long ago as June 21st, 1890, a number which also contained one of David Ferrier's Croonian lectures on cerebral localisation and the second Report of the Hyderabad Commission on chloroform.

"Gifford Nash commenced to practise when much of the surgery of the abdomen was still in its infancy. In 1887 Frederick Treves had performed the first deliberate appendicectomy, and Nash, embarking only two or three years later upon his own earliest appendicectomies, lacked the good fortune to have actually witnessed the operation carried out by another surgeon. It was not otherwise with gastric surgery; for Nash's earliest operations on the stomach, performed in the early nineties, were not modelled on anything observed in the theatres of other operators; he had to direct his own skilful hands. He was not long behind Sir Arbuthnot Lane and Sir Charles Ballance in successfully operating for infective thrombosis of the lateral sinus and ligaturing the internal jugular vein for this condition. One of his earliest contributions to surgical literature dealt with torsion of the undescended testicle, and although Nicoladoni had drawn attention to this complication in a foreign journal in 1884, Nash was the first British surgeon to describe the condition in a short paper in THE LANCET of June 6th, 1891. Not only can priority among British surgeons be claimed for him in recording this complication of the undescended testis, but he later recorded cases in which he was actually able by manipulation to successfully untwist the torsion, while he made other contributions to the literature of this subject. He seems to have had almost a flair for encountering the unusual in the surgery of that now-distant period, and his writings refer to such variegated activities as a successful nephrectomy for a pyonephrosis of the left half of a horseshoe kidney in an infant of 16 months, and the successful removal of a torsion of the testis in an infant 9 days old; he dealt successfully with a case of acute pancreatitis only five years after Fitz's classical description of that disease in 1889, and also with such a rarity as a primary hyperplastic tuberculosis of the stomach and duodenum.

"While his house surgeoncy to Sir Henry Morris in 1887 naturally led to a sustained interest in the problems of renal surgery, his surgical apprenticeship within the walls of Middlesex Hospital, when Bland Sutton was unravelling the pathology of ectopic gestation and indicating its surgical treatment, doubtless stimulated his enthusiasm for the surgery of this condition and may have been responsible for the numerous papers on this subject that frequently came from his pen. In the problems of cancer he also took a close interest. In 1902, as president of the South Midland Branch of the British Medical Association, he delivered an address containing much of interest in connexion with 'cancer houses,' 'dual cancer,' and other points dealing with the ætiological aspect of the disease.

"Nash's wealth of surgical experience was immense, and any appeal would always result in his unburdening himself of an abundance of information germane to the question at issue and of value to the interrogator who sought his advice and aid. He had capable hands and profound judgment; he inspired confidence everywhere, no less in the houses of the rich than in the cottages of the poor; he radiated enthusiasm amongst those who were his colleagues in the work of his life."

The interests of Gifford Nash were very wide and in all of them his energy and enthusiasm were displayed. In connexion with the Bedford hospital the County Guild was his conception and he was vice-president from its foundation nearly 30 years ago. He took a deep interest in the successful development of the Workers' Hospital Fund, another movement where he functioned as vice-president, and he was chairman of the convalescent home committee from its inception to the end of his life. In the development of the paying wards and the maternity department of the hospital he took a keen interest. Mr. J. A. Whitchurch, chairman of the managing board, in paying tribute to his activities, said that in the early years of the paying wards nearly two-thirds of the patients were under Gifford Nash's care, closing with the words, "For the last 23 years one of my most treasured experiences is the friendship, help, and advice of one I honoured and loved, a great surgeon, and a great gentleman, Walter Gifford Nash."

Mr. Gifford Nash married Miss Catherine Moore Wilson, daughter of the late Mr. Walter Wilson, of Plymouth, who survives him with six children, among whom are Mr. F. W. G. Nash, F.R.C.S., and Captain H. K. G. Nash, R.A.M.C.

ARTHUR SHILLITOE, M.B., B.Chir. Camb., F.R.C.S. Eng.

THE death has been announced of Arthur Shillitoe a well-known authority both on syphilis and life assurance problems. Born in 1860, he was educated at Cambridge, where he graduated as M.B., B.Chir. in 1894. He went for his clinical training to Guy's Hospital, and took the English double qualification in 1893, proceeding to the F.R.C.S. Eng. two years later. At Guy's he acted as assistant demonstrator of anatomy, and his first appointment showed the direction which his work would take and which was hereditary, for he became assistant surgeon to the London Lock Hospital and surgical registrar. While at the hospital he made many communications to medical societies and to the medical press, notably an investigation of a series of cases of pseudo-chancre which was published in these columns on May 30th, 1896. This communication made while Shillitoe was registrar at the Lock Hospital was mainly founded on observations made by his father in private practice, and the information as to recurring chancres supplied in this

[Photograph by Elliott & Fry

MR. SHILLITOE

paper was of a valuable nature, pointing to the elucidation of frequent difficulties in diagnosis. Later he collaborated in the production of D'Arcy Power and J. K. Murphy's "System of Syphilis," to which he contributed the section dealing with the primary lesions and early secondary symptoms of syphilis as seen in the female. In 1904 we published an article by Sir Arthur Keith, then lecturer on anatomy at the medical school of the London Hospital, and Shillitoe on the preputial glands of man, in which the embryological side of the subject was fully dealt with. Shillitoe was medical officer to the Atlas Insurance Company, and out of his experience arrived at certain conclusions on the relation of syphilis to life assurance which he published in the Transactions of the Life Assurance Medical Officers' Association in 1906. Thus in many directions he furnished the profession with practical knowledge in circumstances where exact diagnosis was of the first value.

Shillitoe had retired from active work for some time, and his death occurred suddenly in a Plymouth nursing-home on July 22nd.

DR. AMREIN

THE death in Zurich on August 2nd of Dr. Otto Amrein will be noted with regret by all who are interested in the climatic treatment of pulmonary tuberculosis. He was 62 and suffered from cardiosclerosis. Amrein's life coincided with the rise and decline of Arosa as an invalid resort. When he settled there shortly after qualifying in medicine at Zurich Jacobi's big German sanatorium had already been going for some years, and Dr. Roemisch, who is still living in retirement, was seeing most of the private patients who had begun to flock to the village of Arosa as an alternative to the more sophisticated town of Davos. Rüedi had taken with him a considerable clientele when he left Davos for Arosa, but did not long survive to enjoy it. Amrein's success was assured from the start; he was a first-rate clinician, cautious and sagacious, and with the personal qualities that retain the patient's confidence through months or years of monotonous life—for it must be remembered that sanatorium régime in the early years of the century was simply the application of hygienic-dietetic principles with no daily diversions such as artificial pneumothorax or gold injections. For twenty years or so Amrein was content with supervising his large practice in hotels and pensions, over the management of which his position enabled him to exert a controlling influence; but in 1914 was opened the sanatorium Altein in which was embodied every item of comfort and equipment designed for the kind of life he wished his patients to live. Circumstances combined to prevent it ever becoming the success he hoped. The death of a prominent financier, when it was half built, deprived it of the architectural features which would have made it a joy to behold as well as to live in, and the war gradually stemmed the flow of foreign patients, although later on the Red Cross was glad to find such a chance for its invalided officers. As the economic situation in Europe darkened one sanatorium after another in Arosa had to close its doors for patients, opening only for a month or two in the winter for sport. Through all these vicissitudes Amrein was the daily guide and counsellor of hundreds of phthisical English patients, many of whom owe him the health they now enjoy. He was always on the side of prolonged bodily rest, although he learnt that it was possible to make exceptions for the Anglo-Saxon temperament. He was immensely respected and a little feared by his colleagues, and consulted by the local authorities in every matter touching the place as a health resort. His familiar figure, with the slight limp which never interfered with his activities, will be much missed. If he had not been a doctor Amrein could have easily made his mark as a musician, for he was a pupil of the great Joachim, and continued throughout his life to take part in charitable concerts.

PHILIP JOHN LE RICHE, M.R.C.S. Eng.

THE death occurred on July 27th of Dr. P. J. Le Riche, who had been in practice before his retirement for some 30 years in Worthing. He was born at St. Heliers, Jersey, in 1863, the son of Mr. F. J. Le Riche, and he was educated at the Victoria College, Jersey, and University College, London, receiving also some of his medical training at Guy's Hospital. His first bent was towards ophthalmology, and he acted as an ophthalmological assistant at Moorfields, but later he made several voyages as surgeon to a steamship line. He then set up in practice at Worthing, and at the outbreak of war was in charge of The Grange auxiliary hospital, Worthing, and held also a captain's commission in the 4th Battalion, the Royal Sussex Regiment (T.A.). After the war he continued to practise in Worthing and became widely known both as a doctor and for various other activities. He was a useful local cricketer, was prominent in masonic circles, and under the name of "Kish" wrote a book called "Creation's Dawn," which attracted considerable public attention. Dr. Le Riche had for many years been a widower.

HOSPITAL COÖRDINATION IN LONDON

THE London Voluntary Hospitals Committee and the London regional committee of the British Hospitals Association have amalgamated under the title The Voluntary Hospitals Committee, County of London. The new committee represents both the governing bodies and the medical staffs of the 108 voluntary hospitals in the county of London, and will continue the consultations which have been taking place between the L.C.C. and the Voluntary Hospitals Committee since 1930, under Section 13 of the Local Government Act, 1929. A subcommittee has been appointed to meet representatives of the hospitals and medical services committee, L.C.C. The new committee will be an integral part of the B.H.A., and its functions will include the consideration of all subjects which may affect the voluntary hospitals within the county. The honorary officers are: chairman, Mr. Oliver N. Chadwyck-Healey; vice-chairman, Dr. A. M. H. Gray; treasurer, Sir Herbert Samuelson; secretary, Prof. Leonard S. Dudgeon.

KING GEORGE HOSPITAL, ILFORD.—Figures issued by the King Edward Hospital Fund for London show that out of a group of twelve hospitals with from 12 to 200 beds, this hospital was the only one with no available beds vacant, and the cost of maintenance per bed is less than the average. Income and expenditure for the first half of the year show the total income to be £14,000, as compared with £12,593 in the first half of 1934, and the expenditure was £18,509, an increase of £2962.

CORRESPONDENCE

TOXICITY OF AVERTIN

To the Editor of THE LANCET

SIR,—The report by Dr. Cole in your issue of August 3rd, and the letter from Sir Francis Shipway in your last issue, prompt me to record an example of the value of avertin. In August, 1932, two boys, brothers, aged 12 and 9, were admitted to the Dorset County Hospital suffering from meningitis, the organism of which was stated by the pathologist to be Pfeiffer's bacillus. Both boys were treated with continuous avertin anæsthesia, and apart from the initial lumbar puncture for diagnostic purposes, no other treatment was adopted. Full doses of avertin were given, three or four times in each 24 hours. These would cause the children to sleep for four or five hours; the head retraction disappeared, and there was no crying. It was possible to feed the children while they were coming round from the anæsthesia, though, in addition, fluids were given by the rectum. When the anæsthesia passed off, the heads of the children would retract, and they would begin to cry, and occasionally to scream.

After four days the younger child recovered sufficiently to stop the avertin, and in a week we were able to do the same with the brother. Recovery was complete, except for deafness in the older child, which persisted for a further week, and then cleared up completely.—I am, Sir, yours faithfully,

R. E. HOPE SIMPSON.

Beaminster, Dorset, August 9th.

PROCTALGIA FUGAX

To the Editor of THE LANCET

SIR,—Dr. Thaysen's article has served to arouse my interest in two cases which have shown symptoms similar to those he describes. In both cases the following features were common:—

1. The attacks were of uniform severity and of constant duration, each attack lasting about 5 minutes.
2. The pain was gnawing and cramp-like in character, and was neither preceded by nor followed by tenesmus or flatus.
3. The pain was localised in the rectal region immediately above the sphincter ani.
4. The attacks disappeared spontaneously and were followed by feelings of exhaustion and lassitude, and in both cases resulted in the development of an anxiety state. They were unaccompanied by any disturbance of intestinal function.
5. Rectal examination digitally and per sigmoidoscope failed to reveal any causation for the attacks, and during an attack there was no spasm of the anal region.
6. No method of treatment was of any avail.

In both these cases the attacks came on within a period of 30 minutes following masturbation, and depended, I suggest, upon venous engorgement following sexual excitement.

I am, Sir, yours faithfully,

WILLIAM BLYTH.

The Mental Hospital, Riccartsbar, Paisley, August 10th.

To the Editor of THE LANCET

SIR,—As a sufferer from this complaint for a quarter of a century may a humble member of the profession venture to offer an opinion on what seems to puzzle his betters? I first experienced the affection after rashly leaving off my natural-wool underclothing in a bleak April spell. Since then I can always tell the prevalence of an east wind by my own feelings and without looking at the weather. As to treatment, I have always got relief from guaiacum and sulphur in tablet form, but whether it is the sulphur or the guaiacum that is the specific I cannot say. What I do claim is that the trouble is a neuritis, and I have read in Hilton's "Rest and Pain" (I cannot at the moment find the reference) that there is no less reason why the rectum should be subject to neuritis than any other part of the body. At first I feared *everything* including cancer as the cause and consulted a surgeon, but he could find nothing amiss locally, and anyhow I am still alive!

I am, Sir, yours faithfully,

August 9th. A SEPTUAGENARIAN.

PRURITUS

To the Editor of THE LANCET

SIR,—I have read and appreciated Lord Horder's address printed in your last issue. My own view is that X radiation should be regarded as a useful method of desensitisation in these cases. As Lord Horder has so aptly stressed, it is the underlying general ætiological factors which must be discovered and remedied. Failure in this direction will inevitably lead to a recurrence of the pruritus when further desensitising doses of X rays will give at best but temporary relief. In my experience cure may be effected in more than 50 per cent. of cases, and I do not believe "heavy doses" to be ever necessary.

I am, Sir, yours faithfully,

Putney, S.W., August 13th. WARNER COLLINS.

SIGNIFICANCE OF PERSISTENT HIGH BLOOD PRESSURE

To the Editor of THE LANCET

SIR,—Dr. L. N. Jackson's article in your issue of August 10th is most interesting, but I should like to join issue with him on one point. He states that patients with essential hypertension do badly on insulin. Surely this is too sweeping? Indeed diabetic accumulations in the blood probably contribute to the production of arterio-sclerosis.

I have now under my care 11 diabetics who are the subjects of persistent high blood pressure and have taken insulin for periods varying from eight months to six years with no ill-effects. All are over 55 years of age, and four are over 70. The systolic blood pressures range from 180 to 280 mm. Hg and the dose of insulin from 10 to 60 units a day. One patient has been able to leave off insulin owing to increased tolerance for sugar, and two have reduced it.

I believe that diabetics with high blood pressure derive nothing but benefit from insulin. Whether hypoglycæmia is harmful is another question. Joslin and others consider it dangerous in cases of angina pectoris and arterio-sclerosis, and it is reasonable to suppose that a reduction of the sugar content of blood passing through narrowed coronary arteries may fatally starve the heart. In my own patients with hypertension, the lowest point found during routine examination of the fasting blood-sugar was 0·08 per cent.—on the border line of hypoglycæmia—but one patient had an attack of hypoglycæmic coma when on holiday, and returned home apparently none the worse.

It seems unjustifiable to withhold insulin from diabetics with high blood pressure, either on theoretical or practical grounds; although when there is reason to suspect coronary arterio-sclerosis it is well to avoid hypoglycæmia.

I am, Sir, yours faithfully,

Hove, August 13th. G. M. WAUCHOPE.

POOLED HUMAN MILK FOR INFANT FEEDING

To the Editor of The Lancet

Sir,—In your annotation last week on pooled human milk for use in the feeding of premature infants and for babies suffering from alimentary disturbances, you report the doubt that Prof. W. Catel of Leipzig has thrown on its value. He has found that the mortality and morbidity of prematures is higher when the breast milk given is sterilised by heating than when it is given fresh. By this and other work he has been led to challenge the value of sterilised human milk.

It would be a pity to leave the matter at this point. The lesson to be learned from his observations is that sterilisation of breast milk by heating results in a reduction of those antibodies on which much of the comparatively high (passive) immunity of breast-fed infants depends. This is exactly what one would expect. Clearly the problem is to know how pooled human milk can best be stored so that deterioration does not occur. Some of your readers may like to know that breast milk, after being collected aseptically, may be stored at −10° C. in a refrigerator. In centres where this method is followed the milk, frozen solid, seems to keep indefinitely, and satisfactory results are obtainable by its use. This does not diminish the value of Prof. Catel's comparison between heated and fresh breast milk; indeed the evidence he reports of the deleterious effect of sterilisation by heating gives force to the argument in favour of low-temperature storage.

I am, Sir, yours faithfully,

Reginald Lightwood.

Brook-street, W., August 13th.

DR. GRIFFITH EVANS

ON HIS HUNDREDTH BIRTHDAY

In celebrating the centenaries of distinguished medical men we are seldom able to enjoy their presence among the celebrants. The hundredth birthday of Dr. Griffith Evans therefore gives peculiar pleasure to his colleagues and successors, and they are glad to recognise his services in two branches of medical work, for he is not only a graduate of medicine but also, and primarily, the Father of the Veterinary Profession in this country.

Dr. Evans was born at Towyn in Merioneth on August 7th, 1835, and qualified from the Royal Veterinary College at the age of twenty. He obtained a commission in the Army in 1860, and while stationed at Montreal paid a memorable visit to the armies of the North in the American Civil War, receiving his authorisation in a personal interview with Lincoln. The thesis which gave him his medical degree at McGill University in 1864 is said to have recognised the infectious nature of tuberculosis and emphasised the desirability of open-air treatment. Service in India followed, and in 1880, when he was inspecting veterinary surgeon to the Government of Madras, he made the investigations on surra which have won him lasting repute. Surra is a troublesome disease of horses, mules, camels, and cattle, occurring in India, Burma, Indo-China, and North Africa, and in discovering the causal organism Evans was also demonstrating, for the first time, that trypanosomes are capable of causing illness. He showed that the *Trypanosoma evansi* of surra is transferable by subcutaneous injection and by passage into the stomach, and his observations were permanently commemorated when Steel gave the organism its present designation. The other species or variety which bears his name is *Filaria sanguinis evansi*, isolated in 1882 from the blood of camels.

Dr. Evans retired from the Army in 1890, and before going to Bangor lived for some years in Cardiff where his daughter, Dr. Erie Evans, was in practice, and where he later renewed old acquaintance with Sir William Osler. His services to veterinary medicine have at various times been recognised by the conferment of the honorary degree of D.Sc. by the University of Wales, the Steel medal of the Royal College of Veterinary Surgeons, the Mary Kingsley medal of the University of Liverpool, and the freedom of Bangor.

On his hundredth birthday Dr. Evans was confined to his room, for he has lately fractured both thighs; but he was able to entertain a series of visitors bearing messages of congratulation. First among them were members of his own family, including Dr. Evans and Mrs. Garfitt (daughters), Miss Garfitt (niece), Mr. and Mrs. G. H. Jones (son-in-law and daughter), Mr. Evans (son), and Mr. Bevan Jones (grandson). Sir Frederick Hobday, Captain W. H. Savage, and Mr. W. T. Rowlands represented the veterinary profession, and Sir Frederick brought a congratulatory scroll from the Royal Veterinary College signed by the Duke of Gloucester as president and himself as principal. In accepting this scroll Dr. Evans expressed his gratitude at receiving it from the College where he began his professional career and spoke of the benefits he had received from his teachers there—notably Spooner, Simmons, and Morton. Recalling his early adventures in microscopy he told how he had made slides of blood—his own and that of animals—under different conditions of fasting and digestion. "I was the youngest student at College," he said, "and I was a ruminating animal!"

Telegrams were then delivered from the King and Queen, the Prince of Wales, the Royal College of Veterinary Surgeons, the Liverpool School of Tropical Medicine, the Welsh National School of Medicine, and other bodies. The mayor and town clerk of Bangor brought an address from the city council, and Dr. Evans warmly thanked them for expressing the friendship of "the people amongst whom I have lived." A message from Mr. Lloyd George, his fellow freeman of Bangor, referred to the pride felt by the Principality in Dr. Evans's lifework.

White Sticks for Blind Persons.—Just before the House of Commons rose Sir Ian Fraser asked the Minister of Transport if he was aware that more than 4000 blind persons have purchased or been given white walking-sticks for use when walking alone to indicate to motorists that they were blind; and if he would help to make the significance of these white sticks more widely known among the motoring public by giving instructions that a query with regard to them should be included in the driving tests now being given, and by including a reference to them in any future editions of the highway code or other propaganda which he might issue.—Mr. Hore-Belisha replied: I have tried to assist the object which my hon. friend has in mind, and I have let it be known that the carrying of white sticks by the blind has my approval and support. I am always ready to advance the project to which my hon. friend refers by any means open to me and it will certainly be relevant to consider, when the highway code comes to be revised, whether it would be appropriate to include advice on this subject. On the other hand, it should be borne in mind that there are certain possible objections to this course; for example, blind people might rely too much on their sticks, the sticks might be used by people who are not blind, and people who are blind or nearly so and did not wish to use the sticks might be prejudiced in the event of an accident.

MEDICAL NEWS

Westminster Hospital Medical School

The annual dinner of old students of this school will be held on Saturday, Sept. 28th, at the Trocadero Restaurant, Shaftesbury-avenue, London, W., when the chairman will be Dr. Vivian Orr. On Sept. 28th and 29th a morning course of lectures open to all medical practitioners will be held at the school. On Monday, Sept. 30th, Major Ian Hay Beith will deliver the inaugural address at the Caxton Hall, S.W. He will speak on the Privileged Profession.

Society for Provision of Birth Control Clinics

A lecture on the theory and practice of contraception will be given by Dr. Gladys Cox on Friday, Sept. 13th, at the Walworth Women's Welfare Centre, at 6 P.M. At the centre demonstrations will be given at 6 P.M. and at 7 P.M. on Friday, Sept. 20th, and at the same hours on Friday, Sept. 27th. The fee for the lectures and demonstrations at the centre is 5*s.*; they are open to medical practitioners and to students who have completed their gynæcological course, and those wishing to be present are asked to signify at which of the alternative hours they wish to attend. The address of the society is 153A, East-street, Walworth-road, London, S.E.17.

Post-graduate Courses in Berlin

An introductory course on homœopathy will be held from Oct. 14th to Nov. 9th by the Berlin Academy for Post-Graduate Medical Study. Other courses will include diseases of the throat, nose, and ear (Sept. 30th–Oct. 12th); infectious disease (Sept. 30th–Oct. 5th); internal medicine (Oct. 7th–19th); eugenics (Oct. 7th–12th); tuberculosis (Oct. 21st–26th); and surgical treatment of intrathoracic diseases with special reference to pulmonary tuberculosis (Oct. 28th–Nov. 1st). Special courses in all branches of medicine, with practical work, are held every month. Further information may be had from the Academy at Robert Koch-Platz 7 (Kaiserin Friedrich Haus), Berlin, N.W.7.

King's College Hospital

Mrs. Kate Madders, M.B., has been awarded a Halley Stewart fellowship in order to continue investigations under the direction of Dr. R. D. Lawrence in the diabetic clinic of the hospital.

Bromley Hospital

The building of the £35,000 extension at this hospital has now begun. Two new wards are being added, a massage department provided, and the nurses' home extended.

Three Counties Hospital, Arlesey

A new nurses' home to house 102 nurses is to be built on the hospital estate. The estimated cost is over £24,000, and the three counties Bedfordshire, Hertfordshire, and Huntingdonshire have been asked to approve the scheme so that building may begin before the winter.

Crewe Memorial Hospital

The foundation-stone of a new women's ward has been laid at this hospital. The ward will complete the extensions embarked upon a few years ago. Last year 784 patients were treated and the cost of maintenance was over £5000.

North Devon Infirmary

There has been a large increase in expenditure at this institution, mainly due to alterations and repairs, but the building is now in a good state of repair. Ordinary income amounted to £5365, a decrease of £278. Patients' payments were down by £269, and contributory schemes showed an increase of £265.

Derbyshire Royal Infirmary

In less than fifteen months £43,000 has been subscribed towards the £90,000 needed for the new ward block at this hospital.

Manchester public health authority has decided to organise a joint advisory board for the purpose of securing greater coördination and efficiency among the hospitals in the area.

Mr. Leslie Paton has been elected an honorary member of the American Medical Association.

Tewkesbury's New Hospital

This hospital, which has been built at a cost of about £9000, was opened recently.

Putney Hospital for Incurables

The Duchess of York has opened a new nurses' home at this hospital. The home has been needed for some time but funds were lacking. About £10,000 is still wanted.

Hull Royal Infirmary

This institution has had a deficit for six successive years and the accumulated debit balance is now over £28,000. Annual subscriptions and donations are lower than they were five years ago, while the infirmary's accommodation and expenditure have increased by 35 per cent.

Cardiff Royal Infirmary

A ward has been named after Sir William Diamond, the chairman of this institution, in recognition of his 15 years' service to it. When he became chairman the bank overdraft was £70,000, which has since been wiped out.

Sequel to a Pilgrimage

Thirteen cases of enteric fever are reported from Glasgow and neighbouring counties about three weeks after the return of pilgrims from Lourdes, and it is suggested that infection occurred somewhere on the journey. A case at the Fazackerley Hospital, Liverpool, is also attributed to the same journey.

Gallipoli and Salonika Revisited

Those who served in the Near East during the late war will be interested to learn that a reunion pilgrimage cruise to Gallipoli and Salonika has been arranged by a committee of ex-Service men. Those taking part will leave Liverpool in the *Lancastria* on May 1st, 1936, returning on the 23rd, and calls will be made at Malta, Gallipoli, Salonika, and Istanbul. Particulars may be had from the Joint Hon. Secretaries, Gallipoli and Salonika Pilgrimage Committee, 3, Shaftesbury-avenue, Chesterfield. Early application is advised.

AN EDINBURGH LABORATORY

IN his latest annual report as curator Sir Robert Philip shows that valuable work is continuously in progress at the laboratory of the Royal College of Physicians of Edinburgh. Over 15,000 pathological and biochemical reports were issued in 1934, including 3468 histological reports most of which were for the determination of malignant growth. Of late years the reports of tumour growths have been collected for investigation, and a "cabinet gallery of tumours" has been formed which includes some notable special collections—for example of bone sarcomata and tumours of the brain. This collection has been of special value to the Cancer Control Organisation for Edinburgh and the South-East of Scotland, and specimens of special tumours have been sent to several centres both in this country and abroad. The Cullen prize has been divided between Lieut.-Colonel A. G. McKendrick, superintendent of the laboratory, and Sir Frederick Menzies, medical officer of health for the county of London, and the Lister fellowship has been awarded to Dr. Edith K. Dawson for her work on the pathology of the breast. The medical profession in Edinburgh are exceptionally fortunate in having this excellent laboratory at their disposal.

Appointments

CRAIG, N. S., M.D. Manch., has been appointed Medical Superintendent, St. Peter's Hospital, L.C.C.

GILL, W. J., M.D. Aberd., F.R.C.S. Edin., Medical Superintendent, Paddington Hospital, L.C.C.

Vacancies

For further information refer to the advertisement columns

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

Ashford Hospital, Kent.—H.S. £150.

Aylesbury, Royal Buckinghamshire Hospital.—Second Res. M.O. At rate of £150.

Barnsley County Borough.—M.O.H., &c. £900.

Belfast, Royal Maternity Hospital.—Two Res. H.S.'s. At rate of £100 and £52 respectively.

Birkenhead Municipal Hospital.—Sen. Res. M.O. £350. Also Res. M.O. £300.

Birmingham Education Committee.—Asst. School M.O. £500.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Res. M.O. £300.

Birmingham and Midland Hospital for Women.—H.S. At rate of £100.

Board of Control, Rampton State Institution for Mental Defectives, nr. Retford.—Deputy Med. Supt. £847. M.O. £515.

Bolton Royal Infirmary.—Res. Surg. O., also Asst. Res. Surg. O. £250 and £200 respectively.

Bootle General Hospital.—H.S. to Spec. Dept. At rate of £150.

Bradford Royal Eye and Ear Hospital.—H.S. £160.

Bristol, City and County of.—Asst. M.O.H. £500.

British Postgraduate Medical School, Ducane-road, Shepherd's Bush, W.—Cas. O.'s. At rate of £150. Also H.P.'s and H.S.'s.

Burton-on-Trent General Infirmary.—H.S. £150.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. £120 and £100 respectively.

Coventry and Warwickshire Hospital.—Res. Surg. O. £200.

Denbigh, North Wales Sanatorium.—Asst. Tuberculosis M.O. £500.

Denbighshire County Council.—County M.O.H., &c. £1100.

Dewsbury and District General Infirmary.—Sen. H.S. £200.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts. £175.

Dreadnought Hospital, Greenwich, S.E.—Receiving Room Officer. Also H.P. At rate of £200 and £110 respectively.

Dumfries a [illegible] upt. £500.

East Ham [illegible] £300.

Epsom Co [illegible] At rate of £250.

French Hospital and Dispensary, 172, Shaftesbury Avenue, W.C. Jun. Res. M.O. £100.

Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W. Hon. Anæsthetist. 20 guineas.

Guildford, Warren-road Hospital.—Res. Asst. M.O. At rate of £250.

Harrogate and District General Hospital.—H.P. and Cas. O. Also H.S. Each at rate of £150.

Huddersfield, Mill Hill Isolation Hospital.—Res. M.O. £350.

Huddersfield, Storthes Hall Mental Hospital, Kirkburton.—Fifth Asst. M.O. £350.

Hull, Anlaby-road Institution.—Asst. M.O. £350.

Hull Royal Infirmary.—Third H.S. At rate of £150.

Iraq Government.—M.O. Dinars 70 a month.

Kingston and District Hospital.—Visiting Physician. £300. Also Visiting Aural S., Orthopædic S., and Neurologist.

Leamington Spa, Warneford General Hospital.—Res. H.S. to Cas., &c., Dept. At rate of £150.

Leicester City Mental Hospital, Humberstone.—Third Asst. Res. M.O. £350.

Leicester County Sanatorium and Isolation Hospital, Markfield.—Res. M.O. £400.

Leicester Royal Infirmary.—H.S.'s, Cas. O., H.P.'s, Jun. Res. Anæsthetist. Each at rate of £125. Also Jun. Cas. O. At rate of £100.

Lincoln, The Lawn.—Asst. M.O. £300.

Liverpool, Alder Hey Hospital.—Res. Asst. M.O. £200.

Liverpool, City Infectious Diseases Hospitals.—Asst. Res. M.O. £200.

Liverpool Heart Hospital.—H.P. At rate of £100.

Macclesfield General Infirmary.—Second H.S. £150.

Manchester, Booth Hall Hospital.—Two Jun. Asst. M.O.'s. Each at rate of £200.

Manchester Hospital for Consumption, &c.—Res. M.O. for Ear, Nose, and Throat Dept., St. Anne's Home, Bowdon. £200.

Manchester, Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s. Each at rate of £150.

Marie Curie Hospital, 2, Fitzjohn's-avenue, N.W.—Pathologist. £650.

Middlesbrough, North Riding Infirmary.—Third H.S. £125.

Miller General Hospital, Greenwich-road, S.E.—2 Cas. O.'s. Each at rate of £150. H.P. and H.S. Each at rate of £100.

Nelson Hospital, Merton, S.W.—Two Res. H.S.'s. Each at rate of £100.

Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. or H.S. At rate of £100.

Northampton General Hospital.—H.S. At rate of £150.

Northumberland County.—Sen. Tuberculosis Officer. £800.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Norwich, Norfolk and Norwich Hospital.—H.S. to Surg. Outpatient Dept. £200.

Nottingham General Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Peterborough and District Memorial Hospital.—Pathologist. £500.

Plymouth, City General Hospital.—Asst. M.O. Also Jun. Asst. M.O. £300 and £250 respectively.

Plymouth, Prince of Wales's Hospital.—H.P. and H.S. Each at rate of £120.

Portsmouth Royal Hospital.—H.P. At rate of £130.

Preston and County of Lancaster Royal Infirmary.—Two H.S.'s. At rate of £250 and £150 respectively.

Prince of Wales's General Hospital, N.—Hon. Surg. Reg. to Ear, Nose, and Throat Dept. £100. Also Jun. H.P. and two Jun. H.S.'s. Each at rate of £90.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, Kensington, W.—H.P. At rate of £100.

Reading, County Borough, Battle Hospital.—Res. Asst. M.O. £300.

Richmond, Surrey, Royal Hospital.—Jun. H.S. At rate of £100.

Rotherham County Borough Education Committee.—Sen. School M.O. £750.

Rotherham Hospital.—Cas. H.S. £150.

Royal Chest Hospital, City-road, E.C.—Med. Reg. £50.

Royal Eye Hospital, St. George's-circus, Southwark, S.E.—H.S. Also Asst. H.S. At rate of £150 and £100 respectively.

Royal Northern Hospital, Holloway, N.—H.P. Also Obstet. H.S. Each at rate of £70.

Ruthin Castle, N. Wales.—Jun. Res. Physician. £200.

St. Helens County Borough.—Asst. M.O.H. £500.

St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. £125.

St. Paul's Hospital for Diseases of the Genito-Urinary Organs, &c. Part-time Pathologist.

Sheffield Royal Infirmary.—Second Asst. Cas. O. At rate of £80.

South-Eastern Hospital for Children, Sydenham, S.E.—Two Res. M.O.'s. Each at rate of £100. Also Hon. Pathologist. £50.

South London Hospital for Women, Clapham Common, S.W.—H.P. At rate of £100.

Tilbury Hospital, Essex.—H.S. At rate of £140.

Tunbridge Wells, Kent and Sussex Hospital.—H.S. to Ear, Nose, and Throat and Ophthalmic Depts. £150.

University of London.—Graham Scholarship in Pathology. £300.

Ventnor, Isle of Wight, Royal National Hospital for Consumption, &c.—Jun. Asst. Res. M.O. At rate of £300.

Weir Hospital, Grove-road, Balham, S.W.—Sen. Res. M.O. £200. Jun. Res. M.O. £150.

West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each at rate of £100.

Wimbledon Hospital, Thurstan-road, S.W.—Res. M.O. At rate of £150.

Wolverhampton, Royal Hospital.—H.S. for Fracture and Orthopædic Dept. At rate of £100.

Woolwich and District War Memorial Hospital, Shooter's-hill, S.E.—Res. M.O. £175.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Wigston, Leicestershire.

Births, Marriages, and Deaths

BIRTHS

BOLT.—On July 29th, at Great Russell-street, W.C., the wife of R. F. Bolt, M.R.C.S. Eng., of a son.

DAWES.—On August 11th, at Welbeck-street, W., the wife of W. A. Dawes, M.R.C.S. Eng., of a son.

FARNCOMBE.—On July 31st, at Euston-road, the wife of Ronald Farncombe, M.R.C.S. Eng., of a daughter.

GABRIEL.—On August 4th, at Highgate, the wife of W. B. Gabriel, F.R.C.S. Eng., of a son.

THOMAS.—On August 6th, the wife of Clement Price Thomas, F.R.C.S. Eng., of a son.

MARRIAGES

MACCALMAN—DAWSON.—On August 5th, at the Parish Church, Colonsay, Argyll, Douglas R. MacCalman, M.D. Glasg., to Helen Grego Dawson, M.A., elder daughter of Mr. John M. Dawson, M.A., LL.D., of Perth.

SWINBURNE—FENTON.—On August 6th, at Hawkhurst, Spearman Charles Swinburne, M.R.C.S. Eng., to Millicent, widow of G. R. Fenton, the Connaught Rangers, and elder daughter of the late Lieut.-Col. E. H. Montrésor, Royal Sussex Regt.

DEATHS

HAYNES.—On August 6th, at Leamington Spa, Frederic Harry Haynes, M.D., F.R.C.P. Lond., aged 90 years.

MACLEOD.—On August 8th, suddenly, at Edinburgh, William Bernera Macleod, M.B. Edin., Surgeon Captain, R.N. (retd.), aged 67 years.

PORTER.—On August 9th, at Wakefield, Surgeon Vice-Admiral Sir James Porter, K.C.B., K.C.M.G., M.B. Aberd., late Medical Director-General, Royal Navy, aged 83 years.

SPICER.—On August 8th, at Wimbledon Common, William Thomas Holmes Spicer, F.R.C.S. Eng., aged nearly 75.

WILSON.—On August 9th, at a nursing-home, Foden Wilson, M.R.C.S. Eng., of North Birkenhead, in his 72nd year.

WRIGHT.—At his residence, Boulderwood, Woking, after a brief illness, Alfred Wright, C.B.E., L.R.C.P. Edin., M.R.C.S. Eng., late Brevet Lt.-Colonel, R.A.M.C.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

BENJAMIN BRODIE *

BY H. E. MANSELL, B.M. Oxon., M.R.C.P. Lond.
LATE RESIDENT ASSISTANT PHYSICIAN, ST. GEORGE'S HOSPITAL

THE brightness of Hunter's star has tended rather to blind observers to other stars in the surgical firmament, but Benjamin Brodie's biographer and distant successor held Brodie to have brought the most acute intellect and the most powerful mind to the study of surgery, after John Hunter.

Brodie was born in 1783, the fourth of six children; his father, the Member of a Banffshire clan and a good classical scholar, held the living of Winterslow, near Salisbury. He sent none of his sons to school or to a university, but kept them well to their work at home. Of his home life Brodie writes in his autobiography:

> In the summer my brothers and myself rose at 6 o'clock and two hours were devoted to study (generally learning to repeat Greek and Latin poetry or Cicero's orations) before we breakfasted at 8 o'clock. Immediately after breakfast we resumed our studies. We dined at 3 o'clock and were then at our studies again from 4 to 6 o'clock. . . . On two days in the week, when my father was absent on public business, we had half-holidays. We had no other vacations during the whole year except on some grand occasions, such as a cricket match or the first few days of the skating season. . . . The result has been that the habit of being employed in some kind of study became a part and parcel of my nature. . . . Much of my success in my worldly career is, I am convinced, to be attributed to this discipline in my early years.

YOUNG DETERMINATION

The father impressed on his children that they would have to obtain their livelihood by their own exertions. For Benjamin the medical profession was chosen, and it is interesting to note that he disowned any particular liking for that profession and any faith in the special call to certain ways of life which some young men are supposed to have. He wrote that the persons who succeed best in professions are those who, having (perhaps from some accidental circumstance) been led to embark in them, persevere in their course as a matter of duty or because they have nothing better to do.

In a letter written in after-life to his elder son, then sixteen, he mentioned that his own four years between the ages of 16 and 20 were among the most valuable of his whole life.

> It was in that interval of time, he wrote, that I acquired habits of perseverance and industry, and that I learned to direct my attention to a particular object instead of travelling from one subject to another. I think too that I can recollect my having then, for the first time, meditated upon my own character and become sensible of some of my own faults, a branch of knowledge of more consequence than all the Greek and mathematics that schools and colleges can teach to the most zealous student. It is said to be desirable that you should know the world; but it is much more so that you should know yourself. Always keep before your mind the maxim which was inscribed over the Temple of Delphi: γνῶθι σεαυτόν.

After previously studying anatomy in the Hunter School in Great Windmill-street, he entered as a pupil of St. George's Hospital in 1803, and found that for himself at first, as for other students, all was confusion; the niceties of diagnosis, prognosis, and treatment were incomprehensible. The mist soon cleared, when every case became an interesting subject of inquiry. In his own vivid words "a great game was being played in which the stake was often neither more or less than the life or death of a fellow-creature, and in which those among the students who devoted themselves to their business performed a humble yet not unimportant part without any painful feeling of responsibility." Brodie gained some knowledge of materia medica, for by Dr. Baillie's advice, when he had no subject for dissection, he attended a chemist's shop at the corner of Little Newport-street. The proprietor of it, one Mr. Clifton, also practised as an apothecary, exercising his art among the tradesmen of the neighbourhood. His treatment of disease was simple. He had in his shop five large bottles—"Mistura Salina," "Mistura Cathartica," "Mistura Astringens," "Mistura Cinchonæ," and some kind of white emulsion for coughs, and out of these he prescribed for two-thirds of his patients. Brodie did not set this down to his discredit, for

> I have observed (he wrote) that while young members of the medical profession generally deal with a great variety of remedies, they generally discard the greater number of them as they grow older, till at last their treatment of disease becomes almost as simple as that of the Æsculapius of Little Newport-street. There are some indeed that form an exception to this general rule, who, even to the last, seem to think they have, or ought to have, a specific for everything, and are always making experiments with new remedies. The consequence is that they do not cure the patients, which the patients at last find out, and then they have no patients.

GOOD FRIENDS AND PROGRESS RAPID

In May, 1805, Brodie became house surgeon at the hospital, but, like Hunter, resigned the post after a few months in order to teach anatomy at the Windmill-street school. He also at this time accepted a proposal from Everard Home to act as assistant in his private practice and work for him at the museum of the Royal College of Surgeons of England. This latter employment proved to be of critical importance to him, not only because it kept his scientific outlook wide at a time when he might have been tempted to devote himself exclusively to practical surgery, but also because it led to an introduction to the great Sir Joseph Banks, who was president of the Royal Society from 1778 to 1820. At Banks's house he associated with Herschel, Davy, Woollaston, Young, Home, Abernethy, Carlisle, and others who formed the brilliant intellectual society of the day.

In 1808 Brodie was appointed "assistant surgeon to Everard Home"—not to the hospital, for the latter post was begotten later of the out-patient system, which, says Timothy Holmes, "lay like an incubus on all London hospitals." He became full surgeon in 1822, and held office till his resignation in 1840 for reasons which are well worth quoting:

> One of them was that I began to feel the necessity of diminishing the amount of my labours. Then I had long since formed a resolution that I would not have it said of myself, as I had heard it said of others, that I had retained a situation of such importance and responsibility when, either from age or indifference, I had ceased to be fully equal to the duties belonging to it; and lastly, when I saw intelligent and diligent and otherwise deserving young men waiting their turn to succeed to the hospital appointments, it seemed to me that there was something selfish in standing longer in their way, when as far as my own worldly interests were concerned I had obtained all that I could desire.

He was elected president of the Royal Medical and Chirurgical Society in 1839, of the Royal College of Surgeons of England in 1844, and of the Royal Society in 1858. He was the first president of the General Medical Council (1858–1860); president of the Ethnological Society in 1853, and president of the Section of Social Economy in the National Association for the Promotion of Social Service in 1857. He attended George IV., and in 1828 he was made surgeon-in-ordinary to the King. He was subsequently serjeant-surgeon to William IV. and

Queen Victoria, and in 1834 was made a baronet. His "Collected Works," which were edited by Charles Hawkins and published in 1865, contain his autobiography, numerous original contributions to surgical literature, including his masterly treatise "On Diseases of the Joints," and many introductory discourses and presidential addresses, which revealed the width and depth of his knowledge and interests. He died on Trafalgar Day, 1862, in his eightieth year.

PIONEER IN EDUCATION

Brodie revolutionised the teaching of surgery by his example at St. George's Hospital. Until his time the surgeons used only to go round the wards on two days in the week and never attended otherwise, except when there were operations to perform or when they were especially sent for on emergency. Brodie and Robert Keate, who was surgeon to the hospital from 1800 to 1853, were the first persons to be at their post daily, and there was never an urgent case that they did not visit in the evening and not infrequently early in the morning also. No wonder that the effect of so healthy a change was soon visible in the increase of zeal and diligence on the part of the students and in their increasing numbers. It was, in effect, the commencement of Brodie's reputation as a surgeon and teacher of surgery, and of the rise of the St. George's School to the high position which it held during the whole period of Brodie's services there. He also appointed clinical clerks and began to give clinical lectures, the first ever delivered in a London hospital. He always endeavoured to impress on the minds of his pupils the necessity of making and preserving written records of their experiences. To-day, when we hear so constantly of so much that is wrong with our medical curriculum, it is of interest to remember how bitterly Brodie complained that the great mass of students were so occupied by the large (and in his opinion unnecessary) number of lectures which they were required to attend, and in running from one classroom to another, that they really had neither the leisure nor the physical powers necessary for pursuing in any efficient manner the practical study of disease in the wards of the hospital. He considered it a great mistake to compare the examination of young men entering a profession with those for degrees in a university.

"The Senior Wrangler," he wrote, "might be a great mathematician and the first-class man in classics might be a first-rate Greek scholar, but the utmost that could be expected of a young lawyer or physician or surgeon was that he should show that he had laid such a foundation as might enable him to profit by the opportunities of experience presented to him afterwards. To be a thorough master of his profession in the beginning of his career was out of the question and was a thing to be attained only by unremitting study and close observation continued during a long series of years." These views were not applicable to the Fellowship of the College, which Brodie instituted "with the object of ensuring the introduction into the profession of a certain number of young men who might be qualified to maintain its scientific character, and would be fully equal to its higher duties as hospital surgeons, teachers, and improvers of physiological, pathological, and surgical science afterwards."

After Brodie's death a pupil wrote that Brodie was always distinguished for the value of the matter he had to communicate; those who heard him in the early part of his career found him then energetic rather than polished—struggling with the weight and mass of facts stored up in his mind—but in later years his delivery was fluent and perfect. And Sir Henry Acland, also a St. George's man, has said of Brodie, as a lecturer, that none who heard him could forget the graphic yet artless manner in which, sitting at his ease, he used to describe minutely what he had himself seen and done under circumstances of difficulty, and what under like circumstances he would do again or avoid. His instructions were illustrated by valuable pathological dissections which during many years he had amassed, and which he gave, during his lifetime, to his hospital. He considered it to be one of the most valuable and useful collections of the kind in the metropolis, and a similar view was expressed by Osler of the post-mortem records of the hospital, which have been continuous since 1841.

GREAT PUBLIC POSITION

Brodie held a unique position among his contemporaries, and his services were in wide demand. He was consulted by Brunel, the engineer of the Great Western Railway, when that gentleman had shown his inexperience as a conjuror by inhaling a half-sovereign. He attended Sir Robert Peel after his fall while riding up Constitution Hill, and has left a detailed account of the case. He was called as a medical witness in the celebrated trial of William Palmer, and later in the Smethurst case. Here his evidence was short, clear, and decisive, and a *Times* reporter added: "Sir Benjamin Brodie gave his evidence with great clearness—slowly, audibly, and distinctly—matters in which other medical men would do well to emulate such a distinguished example." Holmes, his biographer, comments:

> If all medical witnesses would follow Brodie's example, professional testimony would rise in public and in forensic estimation; we should cease to look on the degrading spectacle of witnesses who seem to be as much retained for one side or the other as the advocates are. They would speak of matters of fact, resting on the sure ground of their own and others' experience, avoiding dubious hypotheses, and the wranglings of pretended "science"; and, speaking in plain English, without bombast or technicality, they would guide and assist the court in forming a just judgment, instead of misleading and confusing it.

Brodie's works repay perusal to-day for their variety of interest and for their qualities of clearness, common sense, and humour. A careful observer of life and all its functions, he studied death with equal care and minuteness, and it is consoling to read that "he had never known but two instances in which, in the act of dying, there were manifest indications of the fear of death." You will remember how Osler recorded from a study of about 500 deathbeds, that the majority of the dying "gave no sign one way or the other; like their birth, their death was 'a hope and a forgetting.'"

Let me end this study of Brodie with another quotation from his autobiography:

> During these thirty-two years of office, the hospital, as far as my profession was concerned, was the greatest object of interest I possessed. Except during the brief intervals of my absence from London, it rarely happened that I was not at some time during the day within its walls. I was indebted to the opportunities which it afforded me for the best part which I had been able to attain. It had rendered my professional life one of agreeable study instead of one of mechanical and irksome drudgery. Some of my happiest hours were those during which I was occupied in the wards with my pupils around me, answering their inquiries, explaining the cases to them at the bedside of the patients, informing them as to the grounds on which I formed my diagnosis and my reasons for the treatment I employed, and not concealing from them my oversights and errors; and all this to kind and willing and only too partial listeners. My intercourse with the students, and I may add, with the patients also, was always to me a source of real gratification; and even now (many years afterwards) these scenes are often renewed to me at night, and events of which I have no recollection when awake come before me in my dreams.

THE RIGHT TO CURE

THE Institute of Identification at Rio de Janeiro publishes official archives containing contributions which are sometimes of more than merely forensic interest. For example, C. Brisard and M. Ducosté[1] both discuss the "right to cure"—more precisely the right of a surgeon to operate—without the consent or even against the will of the patient. The risk run by the surgeon who, in these circumstances decides to operate, of finding himself subsequently the victim of legal proceedings is minimised by neither author. This risk is naturally greatest if the patient dies, but even if recovery follows the patient or his friends may bring an action against the surgeon, especially if some residual disability remains. An instance of the latter would be a ventral hernia resulting from an abdominal section. Brisard quotes a case calculated to discourage well-meant interference. A man hanged himself; was found and cut down by a passer-by; in falling to the ground fractured his thigh; and successfully sued his rescuer for damages! In spite of this example, Brisard concludes that a surgeon must not shrink from exercising his own judgment should the occasion arise; consoling himself with the thought that unless negligence or faulty technique can be proved against him, he has good grounds for hoping that the court will take a lenient view of his case.

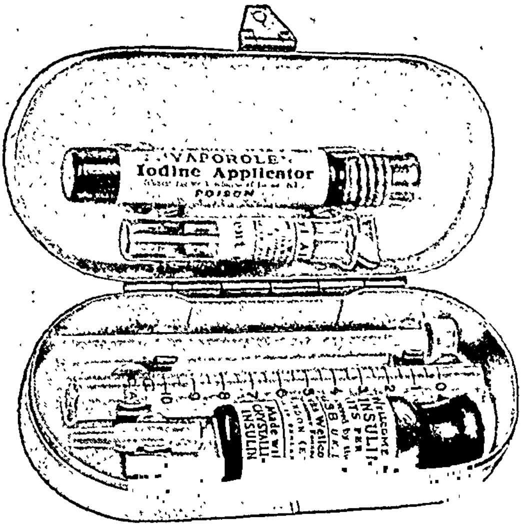
CANCER RESEARCH IN YORKSHIRE

THE annual report of the Yorkshire council of the British Empire Cancer Campaign relates work carried on at two research centres. Prof. R. D. Passey (Leeds) has continued his attempts to induce gastric cancer in rats by infecting them with the *Gongylonema neoplasticum* in the manner first described by Fibiger. Although the animals were successfully infected with a parasitic worm, and although its presence could be demonstrated in the œsophagus and stomach, in no case did cancer develop. This failure is remarkable as hitherto Fibiger's results have been accepted as generally valid.—Dr. Berenblum has continued his investigations on certain skin irritants, such as mustard gas, which have the power to inhibit experimental carcinogenesis by tar. He finds that, while all the compounds which inhibit carcinogenesis are skin irritants, not all skin irritants inhibit the carcinogenesis. With Drs. Orr and Kendal he has studied the action of mustard gas on cellular metabolism. It was found that anti-carcinogenic substances have the power of inhibiting glycolysis rather than respiration of tumour tissue. The substances related to mustard gas which do not inhibit carcinogenesis produce no effect on either respiration or glycolysis, or depress both equally.—Dr. K. J. Bonser, working with special strains of mice, has been able (following Lacassagne) to induce mammary cancer in male mice by repeated injection of œstrin. The positive results were obtained in male mice from a strain having a high incidence of spontaneous mammary cancer in the females. Differences in susceptibility to œstrin do not appear to be related to differences in the normal œstrous cycle.

Prof. E. Mellanby (Sheffield) has confirmed the observation that in a fowl bearing a Rous tumour the filtrable agent is distributed widely throughout the tissue and body fluids. Experiments were carried out in which the experimental induction of cancer in mice by dibenzanthracene was compared with that in mice similarly treated but receiving at the same time injections of the Rous agent from fowls. The results show that the introduction into mice of the Rous agent from the fowl did not significantly modify the development of cancer in mice. Experiments bearing on the chemotherapy of cancer were carried out with the idea of finding substances which would interfere with the respiration of cancer cells. Two such substances were investigated, namely, dilute potassium permanganate and various snake venoms.—Prof. H. W. Florey also submits a short report on various new lines of investigation.

AN INSULIN POCKET-CASE

THE "Wellcome" brand insulin pocket-case (No. 46), made of nickel-plated metal, is specially designed by its measurements to fit comfortably into the pocket. It contains the materials and apparatus necessary for the administration of insulin. The contents are as follows: (1) "Agla" insulin syringe (1 c.cm. graduated in 1/20ths). (2) "Agla" surgical needle (rustless steel), in glass-stoppered container. The container is intended for ethyl alcohol, in which the needle will be immersed, thus maintaining it in an aseptic condition. (3) 5 c.cm. rubber-capped phial of "Wellcome" brand insulin, containing 100 units. (4) "Vaporole" iodine applicator for use when sterilising the skin at the site of injection and the rubber cap on the insulin phial prior to removal of a dose.



The outfit should be specially useful when injections are to be self-administered.

NEW PREPARATIONS

THEOTONE.—This preparation is manufactured in tablet form by Messrs. Allen and Hanburys Ltd., London, the formula being theobromine grs. 5, phenobarbitone gr. ¼. The diuretic action of theobromine has been investigated and established for some years. While it is also a dilator of the coronary arteries, it resembles caffeine in its effects, but its use is apparently not contra-indicated when the blood pressure is high. Its trial in cases of angina pectoris or intermittent claudication before trying sympathectomy has been advocated by certain medical observers. The combination of theobromine with phenobarbitone has been found beneficial in cases of high blood pressure and conditions which may be summarised as those of cardiovascular over-activity.

SALEPSI RUSSI.—This preparation, which can be obtained in solution and in pill form, is designed as a sedative, and claims to have special indications in epilepsy. It is manufactured at the chemical and pharmaceutical works of Russi and Co., Antona, Italy, Messrs. Coates and Cooper Ltd., London, being the English agents. The formula is: 25 drops (1 c.cm.) contain ethyl-phenyl-barbituric acid, 0·05 g.; cascara sag., 0·10 g.; antispasmodic extracts, scopola, stramonium; valerian, 0·04 g.; saccharin, 0·002 g. Messrs. Coates and Cooper inform our readers that specimens will be forwarded upon request.

THE DEATH OF JINNY.—To our issue of July 27th Dr. Kathleen Vaughan communicated a note upon a pet chimpanzee named Jinny, for whom a home was needed. Dr. Vaughan's note brought numerous communications to Jinny's owner, Mrs. Basham, but sad to relate Jinny died on the Monday following the publication of her story. We learn that many offers to receive her as an inmate were received from readers of THE LANCET, and the news of her death is announced here as an explanation why Mrs. Basham has not replied to all the letters.

ADDRESSES AND ORIGINAL ARTICLES

RHEUMATISM AND ITS RESULTS*

By K. DOUGLAS WILKINSON, O.B.E., M.D.Birm., F.R.C.P. Lond.

PROFESSOR OF THERAPEUTICS IN THE UNIVERSITY OF BIRMINGHAM

POLYARTHRITIS is as old as history, indeed it is found in prehistoric man, and was described by Hippocrates with graphic accuracy. Yet the history of rheumatism as we know it is relatively short. Gwilliam de Baillou, a French physician who died in 1616—the year of Shakespeare's death and Harvey's initial lectures to the Royal College of Physicians—was the first to use the word "rheumatism," to apply it to a form of acute arthritis which he distinguished from gout, and to make rheumatism a clinical entity; and it was 60 years later that Sydenham, "the father of English Medicine," first gave us a detailed description of acute rheumatism.

Sydenham knew a lot about gout; he had learned in the hard school of personal experience, for he suffered from it and is said to have died of it. Of rheumatism he said:—

> "The disease comes on at any time, but especially in the autumn, and chiefly seizes those that are in the flower of their age . . . it begins with shivering and shaking and presently heat, restlessness and thirst, and other symptoms which accompany a fever. After a day or two, and sometimes sooner, the patient is troubled with a violent pain sometimes in this, sometimes in that joint, in the wrists and shoulders, but most commonly in the knees. It now and then changes places and seizes elsewhere, leaving some redness and swelling in the part last possessed."

He described chorea too, but does not appear to have associated the two conditions. The picture of chorea is very good:—

> "This disease is a kind of convulsion which seizes children of both sexes from the tenth to the fourteenth year. It manifests itself by a halting or unsteadiness of one of the legs, which the patient draws after him like an idiot. If the hand of the same side be applied to the breast, or any other part of the body, the child cannot keep it a moment in the same posture, but it will be drawn into a different one by a kind of convulsion, notwithstanding all his efforts to the contrary. Before a child who hath this disorder can get a glass or a cup to his mouth he useth abundance of odd gestures, for he does not bring it in a straight line thereto, but his hand being drawn sideways by the spasm, he moves it backwards and forwards till, at length the glass accidentally coming nearer his lips, he throws the liquor hastily into his mouth, and swallows it greedily as if he meant to divert the spectators."

Rheumatic pleurisy was described in exact detail in 1762 by Storck, a Viennese physician, and about 1776 cardiac involvement in rheumatism was first recognised by a Dutchman Van Swieten who practised in Vienna. He said: "Sometimes when the pain of rheumatism in the limbs ceases there arises an anxiety of the breast, a palpitation of the heart and an intermitting pulse." It was in this year that the General Hospital began in Birmingham, and William Cullen, the professor of medicine in Edinburgh, a great pharmacologist and one of Withering's teachers, pointed out that rheumatic joints never suppurated. Some ten years later J. C. Lettsom, the famous Quaker physician, read a paper on cases of palpitation and quoted the case of a boy aged 6 years who had had rheumatic fever followed by cough, respiratory distress, and palpitation, from which he died within three months. A post-mortem examination showed cardiac enlargement and a right lung pneumonia. Matthew Baillie stated that about the year 1788 David Pitcairn in his lectures at St. Bartholomew's Hospital taught that acute rheumatism and heart disease were but different manifestations of a single disease. And about the same date Edward Jenner favoured the Gloucester Medical Society at a meeting held at the Fleece Inn at Rodborough with remarks on a case of disease of the heart following acute rheumatism, illustrated by dissections.

RECOGNITION AS A CAUSE OF HEART DISEASE

In the early years of the nineteenth century the combination of rheumatism and heart disease received a good deal of attention. Louis Odier, a Frenchman educated in England, wrote on this association, while David Dundas collected a number of cases and published them in 1806 in the *London Medical Journal*. W. C. Wells wrote a review of rheumatic disease of the heart in 1810; his name deserves to go down in history for he was the first to describe rheumatic nodules and to note the presence of albumin in the urine in nephritis. But there was no general recognition that rheumatism was commonly associated with heart disease, for John Haygarth, who wrote a "Clinical History of Acute Rheumatism" in 1805, a work based on 170 cases of acute rheumatism, made no mention of involvement of the heart. And as late as 1832 Hope, in a classic treatise on diseases of the heart and great vessels, only mentioned acute rheumatism as a cause of pericarditis in children and young persons. It was not till Balfour's observations in 1816 that we find the first indications of a rational conception of the real pathology of acute rheumatism as a disease, for whereas Sydenham, Haygarth, and Cullen had each regarded rheumatism as essentially a disease of articular structures, Balfour took a far wider view. According to him the seat of the disease was in the cellular membrane, and he thought that all structures composed of this membrane were attacked by the rheumatic process. The significance of his ideas are shown by the following statement. "The cellular membrane abounds everywhere in the body . . . all the blood-vessels receive a coat from it, from the aorta where it emerges from the heart to the minutest capillary that enters a tendon." Similar ideas were held by Charles Scudamore. His "Treatise on Nature and Cure of Gout and Rheumatism" (1819) constitutes the disease as "a peculiar species of inflammation, affecting parts which have a fibrous texture, and most frequently synovial membrane. . . ." He realised, as did Balfour, the remarkable predilection of rheumatism for the synovial membranes of the body and gave as examples of this fact instances of inflammation of the dura mater and of the pericardium. "The pericardium," he stated, "also sometimes becomes the seat of similar morbid action which I conceive as secondary and induced by the inflammation which is affecting some part of the tendinous structures of the heart." The study of heart disease received a tremendous impetus from the invention of the stethoscope by Laennec in 1819. Before this investigation of the heart was most inadequate, its pulsations were seen and felt and the pulse was considered, but the lack of accurate instruments of precision such as watches with second hands made accurate counting difficult if not impossible. The stethoscope directed attention to heart sounds, and immediately after its invention numerous French physicians made important contributions to our knowledge of heart disease. But the instrument took a remarkably long time to come into general use.

---

* The Ingleby lectures for 1935 delivered at the University of Birmingham on June 13th and 20th, 1935.

As a post-mortem finding endocarditis had been noted as early as 1709 by Lancisi, and described in some detail by Morgagni in 1761, but Bouillard in 1836 was the first to point out the clinical signs of rheumatic endocarditis, and he went so far as to state emphatically that endocarditis was not merely a complication of rheumatism, but was one of its cardinal manifestations. Another Frenchman, Lasègue, made a graphic statement well worthy of preservation: "Le rheumatisme aigu lèche les jointures, la plèvre, les méninges même, mais il mord le coeur." ("Rheumatism is a disease which licks the joints, the pleura and the meninges, but it bites the heart.") Babbington, writing in 1821, said that Addison of Guy's was the first teacher to associate chorea and rheumatism, but it was 20 years later that Begbie noted the familial incidence of rheumatism and chorea. In 1843 Sir Thomas Watson pointed out that children as early as 3 or 4 years might develop carditis, and stated that, the earlier they had acute rheumatism the more certainly were their hearts involved. Sir Thomas was the first to stress the supreme importance of rest in the treatment of carditis, and quoted Dr. Warren, who when asked what was good for rheumatism had replied "six weeks." It is said that to Sir Thomas Watson we owe the term "water hammer" applied to the characteristic pulse of aortic disease; it is certain that Corrigan never used it. In 1845 Latham showed how important the stethoscope had become, for he said to his students: "Listen every day to the cases of rheumatic fever, for the endocardial lining may be involved even in the mildest cases." Thereafter an ever-growing host of observers wrote on the subject of rheumatism. Great names appear: Hillier described rheumatic pneumonia; Leherts redescribed the rheumatic nodule; Meynet, Hirschsprung, Warner, and others wrote and described well; and yet the fact that acute rheumatism involved the heart muscle was not recognised before 1876. Degenerative changes were described, but no active inflammatory process until Romberg in 1894 found rheumatic nodules in the heart muscle and regarded them as interstitial myocarditis. The clinical work of Sturges, Barlow, Cheadle, Lees, and Poynton (physicians of the Great Ormond-street School) proved that the muscular tissues of the heart were involved, and in 1904 Aschoff depicted in detail the microscopic appearance of the characteristic lesion of the rheumatic process as we know it to-day.

So we see that whereas early in the nineteenth century acute rheumatism was considered merely a disease of joints, with the occasional involvement of heart, brain, or lungs by a kind of metastatic spread, and that in the occasional cardiac involvement pericarditis was common, endocarditis rare, and myocarditis undreamed of, by the end of the century a very marked change in medical knowledge had caused acute rheumatism to be regarded as a protean disease commonly associated with serious results in as much as a characteristic type of inflammation involved blood-vessels throughout the body, but especially in the heart and synovial membranes. Moreover, it was recognised that rheumatism was essentially a disease of childhood, and that while the involvement of joints and subcutaneous tissues was of small importance, in every case some cardiac damage occurred.

Ætiology

The history of the various theories put forward to explain rheumatism is important and interesting, for no disease has provided a greater diversity of opinion, nor produced problems of greater interest and complexity. The very name rheumatism suggests a condition arising from within, for the rheum was a cold damp humor which flowed down from the brain. All observers have agreed that rheumatism is associated with cold and damp—Cullen taught that cold and damp caused constriction of blood-vessels and so produced local inflammation and fever. Dr. William Prout, who lived from 1785 to 1850, wrote extensively on the chemistry of the body and was responsible for the lactic acid theory. He pointed out that the sweat, saliva, and urine were apt to be very acid in cases of rheumatism, and suggested that an accumulation of lactic acid in the blood was the essential cause of the condition. This theory evoked the alkaline treatment, and was supposed to be proved both by the improvement which followed the use of alkalis, and by certain experimental findings, Sir Benjamin Ward Richardson producing endocarditis by injecting lactic acid into dogs and other animals. For a while lactic acid was used as a treatment for diabetes, and in 1874 Dr. Balthazer Foster (a Birmingham physician) afterwards Lord Ilkeston, reported a case in which six well-marked attacks of multiple arthritis followed treatment with large doses of lactic acid.

As early as 1831 Dr. J. R. Mitchell suggested that acute rheumatism might be a trophic disorder—a disease of the nervous system with changes in the nutrition of the joints—and even before this Haygarth had believed that acute rheumatism could be produced by excessive fatigue from dancing or other forms of violent exercise, and imagined that some part of the brain controlling joints must lie near that part which controlled sweating. Latham taught that cold caused anæmia of the skin and hyperæmia of muscles. This resulted in an abnormal body chemistry and produced an excess of uric acid which caused the joint inflammation. Sir Alfred Garrod disproved this by showing that there was no excess of uric acid in the blood.

T. J. Maclagan who discovered salicin was a theoris of the most courageous type. He believed that th materies morbi of acute rheumatism was not generate in the body, but obtained entrance from without that the disease could not be one of the commo contagious disorders, since it was not infectious conferred no protection against a second attack, an had an indefinite duration. He therefore though that acute rheumatism was allied to malaria— miasmatic disease, liable to appear in low lying damp localities at certain seasons. And since beneficent providence had provided a cure for malar in the bark of a tree indigenous where malaria wa endemic—the remedy for rheumatism was to sought in the bark of a tree which grew in dam low lying sites. He hunted, and he found salic in the bark of the willow, and published his discove in 1876. Within three years of this discovery salici salicylic acid, or sodium salicylate were in gene use wherever acute rheumatism was prevalent, a the old clinicians proclaimed the marvellous amelio tion of the disease produced by these preparations.

BACTERIOLOGICAL AND EPIDEMIOLOGICAL OBSERVATIONS

Ten years later, 1886, Mantle reported the growth of a diplococcus from the blood and joint fluid of a child with acute rheumatism, and since this a number of observers have claimed the discovery of various organismal causes of acute rheumatism. In 1891 Achalme attracted considerable attention by reporting the discovery of a large anthrax-like bacillus from cases of rheumatism, thereby stimulating a good deal of bacteriological research. It is obvious that before this date an organismal cause had been suspected, for Trousseau, Kingston Fowler, Cheadle, Lubarsch, and Buss had all pointed out the importance of the angina faucium—the initial sore-throat—as the portal of entry of an invading organism.

In the Milroy lectures of 1895 Sir Arthur Newsholme published a most important investigation of acute rheumatism from a statistical aspect. He dealt with acute rheumatism only, although he found it confused with gout, acute and chronic polyarthritis of various forms, and many painful affections of the sheaths of muscles and nerves. His figures demonstrated that acute rheumatism was an epidemic disease of temperate climates, most prevalent in the first quarter of the year and especially in January, that predisposed persons became liable to attacks either because of an inherited predisposition, or a particular state of health, especially fatigue, chill, or injury, in certain localities and seasons, for acute rheumatism is an urban disease. He showed that there were epidemic years, and that when the disease was most common the case-mortality was lowest. Taking the Scandinavian countries because of the general excellence of their health returns, Newsholme's figures from the year 1862 to 1892, contrasting towns and countries, showed that:—

In 1888	there	were	1866	cases of acute rheumatism in	Norway	per million inhabitants.
,, 1863	,,	,,	579		,,	
,, 1885	,,	,,	2590		Oslo	
,, 1886	,,	,,	1390		,,	
,, 1883	,,	,,	2600		Denmark	
,, 1892	,,	,,	1600		,,	
,, 1871	,,	,,	5280		Copenhagen	
,, 1892	,,	,,	2720		,,	

Turning to the British Isles he found that 8·4 per cent. of all medical cases admitted to hospitals between 1865 and 1893 were cases of acute rheumatism, and mentions specially that at the Queen's Hospital, Birmingham, the figure was 9·7 per cent. of all medical admissions. He showed that while acute rheumatism occurs all over England, Lancashire has the highest, and Berkshire the lowest death-rate, and he concluded by stating that acute rheumatism was a specific disease due to an infecting micro-organism; that the disease followed an initial sore-throat, tended to relapse and predisposed to subsequent attacks. That the infectivity of any case was very low, probably because the organismal cause was concentrated about the joints, and that the infecting agent was probably a saprophyte which could become a parasite. This was a remarkable summary.

In 1899 Westphal, Wassermann, and Malkoff published a paper of considerable importance. They obtained a diplococcus from a child with acute rheumatism and chorea, and produced arthritis in numerous rabbits by injecting cultures of the organism. They recovered the organism from the inflamed joints of the rabbits, and produced similar arthritis by reintroducing it into other rabbits. Before this paper appeared Dr. F. J. Poynton and Dr. A. Payne had begun to investigate cases of acute rheumatism by bacteriological methods in order to assess the value of Achalme's claims; and in the course of their work they obtained a diplococcus from eight successive cases of rheumatic fever. The organism was a diplococcus, which on culture became a short-chain streptococcus. It was grown from synovial fluid, pericardial fluid, scrapings taken from the mitral valve at autopsy, and the blood, the cultures being obtained by incubating acid milk either aerobically or anaerobically. The organisms were injected into rabbits and produced attacks of polyarthritis, pericarditis, endocarditis of the mitral valve, pneumonia, and even appendicitis. They were demonstrated in rheumatic tissues, in the heart valves, in the subcutaneous rheumatic nodule, and also in the tonsils. Morphologically, the organism found was the same as that described by Wassermann and his collaborators and seems to-day to stand as the most probable cause of the disease. The utmost that can be said against this work is that many subsequent investigators have failed to repeat Poynton and Payne's bacteriological findings. A large number of strains of streptococci, some hæmolytic, some non-hæmolytic, have been found in the sore-throat which precedes the recrudescence of acute rheumatism, and various types have been grown from the blood of rheumatic patients.

Besides the idea that acute rheumatism might be the result of a bacterial infection of the blood and tissues either by a specific organism, or by one of a group of related organisms, or even by any member of a very wide and not necessarily related variety of bacteria, it has been suggested that the condition may result from a toxæmia—the presence of toxins, but not bacteria in the blood stream, such toxins being the products of any of several types of streptococci. Further, as an extension of this idea, it has been mooted that neither bacteria nor bacterial toxins are the responsible agents, but that rheumatism is the result of a peculiar tissue reaction—a special hypersensitivity to the products of bacterial activity. I think that Gustav Singer was the first to suggest this possibility. These theoretical suggestions have resulted in a tremendous amount of highly technical work, chiefly in American laboratories, much of which is inconclusive. About 1926 Birkhaug made a filtrate of the toxin of a non-hæmolytic streptococcus obtained from a rheumatic patient. He discovered that he himself showed a skin reaction to an intradermal injection of this organism, so he injected 1 c.cm. of the sterile toxin filtrate into himself and developed an attack of fever and polyarthritis which was relieved by salicylates. Swift and others have since repeated this observation and have shown that rheumatic patients are generally hypersensitive to intradermal injections of toxin filtrates of streptococci. But although rheumatic subjects generally give positive skin tests to streptococcal endotoxin, about 20 per cent. of normal controls do so too, and a positive reaction can be produced by streptococcal infection or injections of toxin without the production of rheumatism. Agglutinins are present in the blood of rheumatic subjects, and will clump various strains of streptococci. The sera of patients with acute rheumatism, or chronic atrophic arthritis, are particularly strong in agglutinins, but seldom possess as high an agglutinin titre as the blood of scarlet fever patients. Moreover there appears to be no relationship between the titre of the agglutinin and the skin sensitivity. It has even been found possible to determine the quantity of antihæmolysins in blood-serum, substances which inactivate the hæmolysin produced by hæmolytic streptococci of several strains. Patients in the active phase of a rheumatic attack have a high antihæmolysin titre, while those who are non-rheumatic or in a quiescent phase of the disease have a low titre. But the titre of the serum does not vary with the severity of the attack of acute rheumatism, a finding which suggests that there has been an infection with hæmolytic streptococci, which are not the causal organisms of the acute rheumatism, and that allergy is not a factor in the production of rheumatic symptoms. Schlesinger, Signy, and other observers have shown that streptococcal precipitins can be demonstrated in the blood of rheumatic children after the appearance of the pre-rheumatic sore-throat, and that the amount of these anti-bacterial substances reaches its height just about the time that the rheumatic relapse occurs.

We know that streptococci can be the causal organism in infective endocarditis, and that when this happens the blood of the patient develops tremendous antibacterial powers—a high titre of agglutinins and precipitins, and yet such patients do not become skin-sensitive to their infecting organisms. We know too that a hæmolytic streptococcus infection is a frequent prelude to acute rheumatism, and is associated with a raised titre in agglutinins and precipitins in the patient's blood, and skin-sensitivity to streptococcal endotoxin, and an increased blood sedimentation-rate. Yet there is no immunity to subsequent attacks, indeed a definite increased susceptibility. It has been suggested that the ultimate defeat of the protective mechanism in bacterial endocarditis is due to the peculiar situation of the organisms in the heart valves. This is hard to believe, for Lewis and Grant have shown that no less than 26 per cent. of cases of infective endocarditis have congenitally abnormal valves, and Maude Abbott found that no less than 17 per cent. of a series of 555 cases of congenital heart disease died of infective endocarditis. Schlesinger could only find ten cases of infective endocarditis in children under ten years of age during the last 65 years of the Great Ormond-street Hospital records; and acute rheumatism is peculiarly a disease of children. So that it appears certain that acute rheumatism and infective endocarditis are essentially as different in ætiology as they are in clinical features. There is some peculiarity about the rheumatic infection which differentiates it from the various diseases known to be due to streptococci—scarlet fever, erythema nodosum, erysipelas. It may be that some special tissue reaction of the patient is the factor of importance, but a special infection is far more probable. The latest theory is that a virus is the causal agent; this was published by Schlesinger, Signy, and Amies in THE LANCET of May 18th of this year. The suggestion is based upon the discovery of ultramicroscopic bodies in sterile pleural and pericardial fluid from cases of acute rheumatism; and the agglutination of these bodies by convalescent serum. While it is too early to assess the probability of the correctness of this suggestion, it appears to fit in very well with the known facts.

ENVIRONMENT AND PREDISPOSITION

In a few cases the effect of climate upon rheumatic children has been studied experimentally. In New York rheumatism is common, while in Porto Rico it is very rare, so Coburn took ten children from New York where they had had repeated attacks of severe rheumatism to Porto Rico for a period of six months. During the first weeks of their stay in the tropics three of the children continued to have rheumatic symptoms, and improved rather slowly, but then all became symptom-free and remained well for the remainder of their stay. After the return to New York all developed rheumatic recrudescences and two of the children died within eight months. Their diet was unchanged during the experiment, and while in New York they were all given as much sunshine as possible. The outstanding fact learned from this experiment was that in New York the children developed infections of the upper respiratory tract and subsequent recrudescences of rheumatism, and Coburn concluded that the climate of Porto Rico was inimical to respiratory infections and thus protected the children from the recrudescences of their rheumatism.

All the experimental work done so far has not shown one fact which invalidates the suggestion that a streptococcus is the organism responsible for acute rheumatism; indeed, the bacteriological findings and the various experiments with toxins and antibodies all point to a streptococcus infection as an essential predisposing cause. It is certain that the organism is not pyogenic, it is probable that it is non-hæmolytic, and it may be that it is a harmless saprophyte normally which becomes virulent under some special circumstances. These circumstances are not as yet perfectly understood; a change in the organism's essential character, or perhaps an infection of the organism by a virus, or perhaps some variation in the resistance of the patient might explain the known facts.

We know that local epidemics appear in wards as well as much wider epidemics in areas; such local epidemics follow an initial sore-throat, the development of rheumatic symptoms occurring after an interval of 10 to 30 days. The commonest age of onset of rheumatism is about the tenth year, but the condition may appear at any age after the second birthday. Girls are rather more frequently attacked than boys, and there is a definite family incidence (over 200 cases under my own observation show a family incidence of nearly 70 per cent.).

Many experienced clinicians have believed in a rheumatic type of patient—a child who from appearance, colour, and build may be recognised as predisposed to rheumatic disease. These children are possessed of a low resistance to many infections, they take disease severely, and develop rheumatism even in good circumstances. One family of six such children, living under good conditions with well-to-do parents, had most of the exanthemata severely, four mild and two severe attacks of acute rheumatism, and five appendicectomies within ten years. Scarlet fever and diphtheria are fairly frequent precursors of rheumatism, probably because both these diseases appear with special frequency in children with infected tonsils.

Environment plays a most important part in rheumatism, for it is essentially a disease of the poorer classes who live in cities. The importance of cold damp houses has been mentioned, but poor clothing, leaky boots, underfeeding, and overcrowding are at least as important. At first sight it appears curious that the poorest class—the slum-dwellers—do not produce the greatest number of cases of rheumatism, for the disease is seen much more often in the artisan class. The probable explanation is that the high infant mortality-rate in the slums carries off a large number of the susceptible children before they reach the age of rheumatism.

Symptoms

The rheumatic state is not always easily diagnosed in the child, for it may declare itself in any one of several different ways; indeed, some authors have suggested a pre-rheumatic state in which the patient is either losing resistance or gradually being overcome during a prolonged period of incubation. But it seems unnecessary to complicate the picture by such a supposition, for early rheumatism is sufficiently difficult to diagnose and treat successfully. The rheumatic child may be pale and anæmic, listless, tired, one who eats and sleeps poorly and appears to be constitutionally feeble or toxic. Often enough a careful physical examination will show nothing more than this general depression of health. The child may complain of pains, aches about joints or in muscles, made worse by exercise or wet weather, and relieved by warmth, sunshine, or a holiday. These pains may be associated with repeated sore-throats. A characteristic complaint is a right-sided epigastric discomfort not associated with food, often found with a slightly raised temperature and a rather rapid pulse. In other children the infection shows itself by nervous disorders—a child of the quick, bright type becomes unnaturally jumpy or fidgety, and incapable of any sustained attention. Such children are likely to develop insomnia, nocturnal enuresis, tics, night terrors; they react badly to the discipline and stress of school, so that they are especially liable to incur the disfavour of teachers either by their general restlessness or inattention; and as a result may become frankly choreic with the characteristic irregular respiration which precedes the curiously rapid jerky and uncontrolled movements. Lastly there are those who develop frank cardiac signs which usually appear late; often they are recognised only when the heart is already seriously damaged, for the cardiac defect may be the first recognisable sign of rheumatism, although an undiagnosed illness had existed for some time.

Carditis is suggested by malnutrition or actual loss of weight, sweating, and fever, or by a quickened regular pulse—the early disappearance of the normal juvenile variation in the pulse-rate, and a rapid cardiac action during sleep being especially characteristic. The heart sounds change in character, the first sound at the apex becoming soft while the second sound at the base is often accentuated. Next, murmurs appear, the earliest being the systolic murmur which partially replaces the first sound at the apex. Change in the size of the heart in the early stages of carditis is a result of pericardial effusion, and is commonly associated with alteration of the percussion outline of the heart, blurring of the heart sounds, an almost impalpable cardiac impulse, and some degree of pulsus paradoxus. As the heart adapts itself to myocardial damage or valvular defects, enlargement of a permanent nature may appear, and the degree of this increase in size will give a clue to the ultimate prognosis, for the larger the heart the more serious is the damage. Acute dilatation of the heart, as a result of acute rheumatism or any other infection, if it ever occurs, must be exceedingly rare, for years of careful observation and frequent measurement with the assistance of X ray examinations have never shown me a single example of the condition. Nor has any one of a series of keen and critical house physicians ever been able to demonstrate a case in which the heart either expanded or contracted in size within a few days or hours.

Electrocardiographic abnormalities are often present in children with rheumatic carditis, but it is uncommon to find gross abnormalities in the early stages, and most of the defects which appear early disappear or improve under treatment. A minor degree of heart-block is fairly commonly found, and often disappears entirely. Ventricular extrasystoles are sometimes associated with carditis, but may appear in hearts which are otherwise normal, especially in later adolescence. Auricular fibrillation always implies a most serious carditis and an early fatal termination of the disease, but auricular flutter may occur in children who make good recoveries.

Nowadays the fever of acute rheumatism is seldom either high or prolonged, but before the use of salicylates hyperpyrexia and prolonged irregular fever were characteristic signs of the disease. As a rule, the fever settles within a week of the use of adequate doses of sodium salicylate. In the same way both pain and sweating are controlled. Swollen, reddened, and painful joints are characteristic of rheumatism in the adult, but are uncommon in children in whom it is often necessary to handle a joint to elicit pain and discover the periarticular swelling. Sweating is less common in children than in adults, but does occur. It is very rarely severe in a child. Text-books, even by well-known authorities, state that salicylates increase the sweating; this statement is quite untrue, and the cessation of sweating, like the subsidence of the fever, is a sign of adequate salicylate medication.

Perhaps the most characteristic single sign of acute rheumatism is the rheumatic nodule. These nodules appear subcutaneously about the joints, particularly the elbows, knees, carpo-metacarpal joints, wrists, and ankles. They may be found in great numbers or may be very scanty. Sometimes they appear on the scalp about the occiput and occasionally they are found along the iliac crests; frequently they can be felt as peculiar small slightly tender thickenings in the lumbar muscles, even when found nowhere else. The nodule varies in size; generally about the size of a split pea, it may be far larger or smaller, and feels like slightly movable pieces of cartilage, and is almost painless. Usually nodules remain for some weeks, but they may disappear with astonishing rapidity, and almost equally quickly reappear. They used to indicate a very severe type of infection, were associated with pericarditis, and carried a bad prognosis, but latterly they have often appeared in quite mild rheumatism even without any obvious cardiac damage. In several cases they have disappeared under the influence of small doses of Atophan. The peculiar type of inflammation which is characteristic of acute rheumatism may appear in the lung. Indeed, consolidation of this type is by no means uncommon in pericarditis. It may produce few physical signs, or may cause an extensive degree of pneumonia yet without any great disturbance of respiration. Prof. A. E. Naish has made a special study of the rheumatic lung, and finds pulmonary or pleural injury in nearly all fatal cases of rheumatism.

Results of Infection

The characteristic microscopic lesion of rheumatism is the submiliary nodule, a peculiar type of inflammatory focus found only in tissues attacked by acute rheumatism. It is common in heart muscle, endocardium, pericardium, synovial and subcutaneous tissues, and is found in the kidneys, lungs, pia mater, and in the adventitia and media of arteries in many parts of the body. It is perhaps most easily recognised in the myocardium where the nodule forms a striking contrast to the normal muscle and somewhat scanty interstitial tissue.

The characteristic nodule shows four distinct points in its structure :—

1. A poorly staining matrix consisting of fibrin and cellular debris.

2. Certain large cells, varying in shape, elongated or fusiform, with a plentiful deeply staining finely granular cytoplasm and multiple wheel-shaped nuclei (such as are seen in large plasma cells) to the number of from four to ten, although there may be as many as twenty in one cell. These cells are developed from vascular endothelium and may represent sprouts of new capillaries.

3. Plasma cells or fibroblasts.

4. Leucocytes, chiefly small darkly staining mononuclear cells.

The earliest stage of the nodule merely shows a congregation of lymphocytes and plasma cells as the prominent feature, and these may obscure the essentially proliferative nature of the tissue reaction ; but in time the characteristic multinucleated cells appear with their surrounding fibrinous matrix and framework of fibroblasts, and the mononuclear lymphocytes thin out, while later still the lesion is replaced by a patch of fibrous tissue. These foci are always found in association with small arterioles —usually in direct contact in the adventitial or medial coats. They are particularly common in the left ventricle and septum, especially near the base, and appear both frequent and large about the insertions of the mitral valve leaves. The vessels themselves show changes of every degree, local endothelial proliferation is common and may almost occlude the arteriole, yet thrombosis is rare. Sometimes the adventitia is so altered that a cuff of fibroblastic proliferation is seen to surround the vessel like a bead on a string ; and in the larger vessels where nodules appear in the media they produce considerable vascularity with destruction of the normal tissue and ultimate fibrosis. As a result of the rheumatic process the muscle cells of the myocardium undergo striking changes, changes which may be curiously poorly marked to naked-eye examination, and yet are very obvious under the microscope. A species of cloudy swelling, with blurring of the characteristic muscle striation and a diminution of the clear-cut staining of the nuclei is the earliest change. A fatty metamorphosis follows, and is usually present when the rheumatic process has lasted any length of time. And yet, however obvious these changes are, one is always struck by the thought that they seem hardly sufficiently widespread or severe to account for the cardiac failure which was the outstanding clinical feature, and we are constantly aware that our present histological methods are incapable of demonstrating defects of function in highly specialised tissues.

In the chronic case of acute rheumatism—that peculiarly deadly insidious and persistent type which leads to mitral stenosis (it is common to meet patients with mitral stenosis who have never had any symptom of acute rheumatism)—the degree of damage to the muscle may be truly astonishing. Here the auriculo-ventricular junction and the muscle of the auricles themselves is most severely affected, and may be largely replaced by a fibrosis. Where muscle cells remain they may be shrunken and poorly stained, many show fatty globules, and some show patchy pigmentation, although there is nothing like brown atrophy in rheumatism. Emphasis is laid on the condition of the myocardium because it is so important to realise that even in mild cases of rheumatism there is always myocardial involvement, and vascular changes are so marked that some of the smaller coronary twigs always show some intimal thickening. The upper part of the interventricular septum, the neighbourhood of the auriculo-ventricular node and the bundle of His are often damaged, and it is important to state that all observers are agreed that a heart may show both old-standing damage and recent changes which prove that a healed rheumatic process may be associated with a local rekindling of rheumatic inflammation.

Valvular damage is the result of processes of exactly the same histological type as those already described. The endocarditis so commonly seen along the edges of the mitral and aortic valves is always preceded by changes in the substance of the valve leaflets. At the base of the valve, where blood-vessels are relatively numerous, the typical rheumatic nodules appear, and this histological change spreads up into the valve substance ; the common finding of older nodules at the base and earlier stages at the free edges proves that the process advances in this way, and that the valve edge is not infected directly from the blood in the heart. Apparently valvulitis is always a precursor of endocardial thickening at the points of valvular apposition, and the incidence of valve injury depends both upon the vascularity of the valve and the stresses to which the segments are exposed, far greater on the left side because of the higher pressures. The mitral valve is the most vascular, and normally becomes avascular last, the tricuspid is next, then the aortic, and lastly the pulmonary, while stresses affect the mitral valve most, the aortic second, the tricuspid third, and the pulmonary least.

Prevalence of the Disease

Although it is difficult to form any accurate estimate of the prevalence of acute rheumatism in Great Britain, or the frequence of subsequent cardiac disease, it is easy to show certain definite facts by means of figures. G. F. Still found that 13·1 per cent. of his hospital patients suffered from rheumatism, while only 0·7 per cent. of his private patients had this disease, and it is the common experience that in private practice acute rheumatism is a rather rare disease among the well-to-do. G. A. Auden has estimated that 1·4 per cent. of Birmingham elementary school-children have rheumatic conditions—this means nearly 2000 cases of rheumatic infection in children in Birmingham. Sir George Newman has calculated that 0·8 per cent. of all the children attending elementary schools in England and Wales have rheumatic cardiac disease (50,000 cases between the ages of 5 and 14 years.) Carey Coombs showed that 40 per cent. of all heart disease was a result of acute rheumatism and that the average patient with a rheumatic heart died at the age of 28½ years, while no less than 30 per cent. of these patients succumbed between the ages of 11 and 20, and only 7 per cent. reached the age of 50. He found that males do a little better than females at all ages, a result which may in part be due to the influence of childbearing, for while there is no evidence that pregnancy predisposes to recrudescence of rheumatism, it certainly does increase the work of the heart so that the rheumatic mother needs both antenatal care and some extra assistance in the postnatal period if her heart is not to deteriorate. There is definite evidence that repeated gestations do serious damage to women who suffer from mitral stenosis. Coombs also attempted to calculate the incidence of cardiac disease after rheumatism, and states that of children infected before the age of 5 years, nearly half develop heart disease, while among those who first contract rheumatism after 10 years less than a quarter develop cardiac defects. The annual mortality from rheumatic heart disease has been placed as high as 30,000, and as low as 12,000, but it seems probable that the higher figure is more nearly correct.

Rheumatism as its chief result produces heart disease which leads to lessened physical efficiency, produces years of invalidism, and causes early death. Comparatively few of those who have cardiac damage as a result of rheumatism are going to survive to the age of 50 years, and the great majority will be chronic invalids. It is certain that there are in this country more than 50,000 children who have rheumatic heart disease, and not less than 100,000 persons who are cardiac invalids as a result of rheumatism. No wonder that research has been directed to the discovery of the cause and the cure of such a disease, but the chief problem is that of prevention, and the methods by which this may be effected are clear. Among elementary school-children in our cities rheumatism is common; among the same type of children in residential poor-law schools rheumatism is rare; and among the school population of our public schools, male or female, the disease is practically unknown. Eton, a school of 1100 boys, in the Thames Valley, close to the river, has had one case in 17 years.

Treatment

The first step then must be the education of civic authorities so that health may be ensured by well-built houses in sunny smokeless cities which are not overcrowded, and contain spacious suitable play-grounds. The second step should be the education of parents in the wise nurture of children so that their resistance to disease may be high, and good health may be preserved. This implies wise feeding, proper clothing, and adequate changing and drying of wet clothing and boots, as well as the early and careful attention to minor infections, sore-throats, colds, and damaged teeth.

When acute rheumatism, in any of its varied manifestations, does occur it must be recognised early and treated promptly and thoroughly. To-day there are usually three great essentials in treatment. Rest is the greatest of these, and should be complete in the early stages and prolonged if carditis supervenes.

Rest implies that the child is carefully nursed nearly flat in bed, fed and so attended that the patient learns to make no effort or unnecessary movement. In severe carditis it may be necessary to continue this rest for months, and in any case the return to activity should be carefully graduated and watched to see what effect effort has on pulse-rate and cardiac action. By means of really expert nursing the most severe carditis may be prevented from causing serious permanent damage.

The second essential is the removal of foci of infection especially common about the mouth and nose, for infected teeth and tonsils, whether they be the portal of entry of rheumatism or not, depress the general health of children. It may not be easy to decide when a tonsil is infected, but it is certainly abnormal if the glands at the angle of the jaw are enlarged, and such tonsils ought to be removed as soon as is possible having regard to the general condition of the patient, because experience has shown that children with carditis who have had a complete tonsillectomy, and in whom the glands have subsequently disappeared, are definitely less likely to develop serious cardiac defects than those in whom the tonsils remain, or have been imperfectly removed, or the glandular enlargement persists. Tonsillectomy after rheumatic infection has taken place will not prevent recrudescences, but it does tend to protect the heart from the more serious consequences of such recrudescences. Every measure calculated to improve the general condition of health should be employed. The child who puts on weight usually does well.

It has become the fashion to decry or at least belittle the use of salicylates, but there is no group of drugs which has so much influence over the rheumatic infection, nor is there any reliable evidence that any untoward effects follow large doses over a prolonged period. The natural course of acute rheumatism has recently been studied in America by four physicians who watched a series of over 100 children with the disease. These children were not treated with any antirheumatic remedy and the investigators state that they recovered as quickly and left hospital as soon as a series of cases treated by the usual antirheumatic measures. But the history of the condition, especially after 1876 with the introduction of salicin and the almost universal employment of salicylates in treatment, is far stronger evidence than that afforded by this brief study. To a child of 10 years it is quite possible to give grs. 10 of sodium salicylate every hour, or grs. 240 in each day, without any discomfort or even anorexia. To reach this dosage it is necessary to have the child at rest, to allow considerable amounts of fluid with the food; to maintain a milky diet; to ensure a regular action of the bowels; and also to give twice as much of the bicarbonate as of the salicylate of sodium. As children easily tire of any medicine it is useful to give two prescriptions with different flavourings to alternate every two or three hours, and to change the flavouring every three or four days. Salicylates certainly abolish the fever which results from rheumatism; they also remove pain from the affected joints, but they do more than this for they produce a restoration to their normal size and contour and a reabsorption of effusions be they peri- or intra-articular. If then salicylates can produce such effects upon the rheumatic process in the joints, why should not the same result occur in other tissues damaged in like manner? Given in adequate doses salicylate does influence the carditis of acute rheumatism and does modify the course and prognosis of this most serious disease. But every known measure likely to benefit the patient and raise resistance is important, and none can be neglected; tonics, vitamins, and, above all, a prolonged sea visit are advisable—the latter alas often very difficult to arrange. And when all has been done one can only hope that the damage left by the infection will be small, and the resultant incapacity relatively slight.

Let us hope that the future has greater things in store for those susceptible to rheumatism.

DEATH OF ANOTHER AROSA PHYSICIAN.—Following closely on the death of Dr. Amrein, of whom an obituary notice appeared in our last issue, comes the announcement from Arosa, Switzerland, of the death of Dr. Fritz Lichtenhahn, who combined a specialist lung practice with pædiatric work. Many years ago he founded there the Prâsura children's clinic, and he also supervised the treatment of surgical tuberculosis in other institutions. He was only 54 years old.

NEW WARD BLOCKS AT PADDINGTON HOSPITAL.—The construction of a new ward block at Paddington Hospital is necessary in order to provide an adequate maternity unit. The present maternity ward contains only 20 beds, although the number of children born at the hospital rose last year to 500. The new building will consist of four storeys with a central main staircase, and will accommodate 59 more beds. The total estimated cost is £47,760.

THE INDICATIONS AND RESULTS OF PHRENIC NERVE OPERATIONS *

By H. Morriston Davies, M.D., M.Chir. Camb., F.R.C.S. Eng.

MEDICAL SUPERINTENDENT, VALE OF CLWYD SANATORIUM; CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL

There are three operations for paralysing the dome of the diaphragm. There is *phrenic evulsion.* It is generally estimated that at least 10 cm. of the nerve must be torn out in order to be sure that the continuity of all accessory nerve bundles with the distal end of the phrenic nerve have been interrupted. Then there is *phrenicectomy.* This operation demands the section of a length of the main phrenic nerve and of all accessory nerves including the filaments to the subclavius muscle. The third operation is the *phrenic crush.* In this operation the main phrenic nerve is crushed and all accessory nerves are divided. The effect of the crush lasts from two to six months or even longer; regeneration may even fail to take place.

The immediate effect of these operations is paralysis of the hemidiaphragm; the muscle-fibres degenerate, and the dome becomes a sheet of fibrous tissue. It takes about four months for this process to become complete.

As a result of the paralysis there are three changes of the dome—namely, a rise into the thorax, a loss of tone, and a cessation of the normal respiratory movements. The dome either becomes immobile or shows paradoxical movements, sometimes with normal respiration but more often only with forceful efforts such as sniffing. Each of these changes has a separate or combined action on the thorax, the lung, and the disease.

Under normal conditions the rise of the diaphragm into the thorax during expiration is due to three factors: the relaxation of the muscle-fibres, the negative pressure in the pleural cavity, and the positive pressure in the abdomen. The descent during inspiration is, of course, due to the contraction of the muscle-fibres. With the dome paralysed, it ascends into the thorax as a result of the difference between the negative intrapleural and the positive intra-abdominal pressures. When the lung is affected by chronic tuberculosis, although there is loss of elasticity of the lung, there are fibrous tissue changes which may more than counteract the loss of elasticity and, other things being equal, will increase the intrapleural negative pressure, and so exert an abnormal upward drag on the dome. Per contra, in a chronic invalid there may be loss of tone of the abdominal muscles and possibly visceroptosis, and the upward thrust on the under surface of the dome will be lessened.

There are other pathological states, however, which may interfere with the post-paralytic rise of the dome. Thickening of the pleural membranes, particularly of the diaphragmatic pleura, superimposes on the dome a tough layer of tissue which yields but grudgingly to the forces above and below; whilst obliteration of the costophrenic sulcus ties down the margin of the diaphragm. When, further, the pleural thickening is generalised and the interlobar septa are also involved, the chest wall itself tends to become contracted, fixed, and immobile, and so scarcely alters the intrapleural pressure during inspiration.

The extent of the rise of the dome varies greatly after phrenicectomy. It may be barely 1 cm. or as much as 10 or 11 cm.; very rarely has it reached a height of 14 cm.

Effects on the Lung

Before we can appreciate the rationale of the indications and the results, it is essential to understand not only the changes in the diaphragm but also the effect of these on the lung and the thorax in general. There is the influence on the lung of the paralysis of the hemidiaphragm, and of the loss of tone. There is also the influence of the rise into the thorax.

The diaphragm, by its descent, is responsible for the expansion of the lower and posterior parts of the lung; with one half paralysed there is the loss of this expansion force. The consequent deficiency of air entry into these areas of the lung can be observed clinically. To the loss of tone must probably be attributed the benefit of the diminution or disappearance of certain symptoms such as the diaphragmatic cough.

The effect of the rise of the dome on the lung is one which has given cause for much conjecture and argument. In the normal lung there is little doubt but that the greater part of the reduction in the hemithorax is absorbed by a collapse of the base of the lung due to relaxation of the elastic tissue; the higher the rise, the greater is the extent of the lung affected, but it is very unlikely to include the apex. If, however, there are consolidation changes at, say, the base of the lung that part is uninvolved, but the nearest areas of healthy lung tissue will contract.

When there is chronic fibrosis in the apex or upper lobe as a result of tuberculosis, a different mechanism comes into play. This mechanism is identical in principle with that found in the production of a selective collapse by artificial pneumothorax. The elasticity of the healthy parts of the lung will cause the partial collapse of the lung, if for any reason the negative pressure is reduced, but the elastic tissue being perfect it will at once yield again to the expanding force of an increased negative pressure. Pathological fibrous tissue is also ready to contract, given the opportunity, and so powerful is its contracting force that it can drag the chest wall and mediastinum towards each other, exerting a force of which the elastic tissue is quite incapable. When a rise of the dome occurs and the hemithorax becomes reduced in size, the elasticity in the adjacent lung fields causes a reduction of these areas; but the fibrous tissue in the upper lung field is even more responsive to the reduction in the hemithorax; it therefore contracts. During inspiration the increase in size of the chest and the increase in the intra-pleural negative pressure calls for a re-expansion of the lung. The elastic tissue responds to this, but the fibrous tissue does not. The result is a gradually progressive selective collapse of that part of the lung which is fibrosed.

There are other factors, however, which have to be taken into consideration. Reference has already been made to the possible impeding influence of changes in the diaphragmatic pleura. Thickening of this membrane must interfere with the rise of the dome, and yet at times it is surprising to what extent the dome may rise after phrenicectomy despite a known thickening of the membrane. The filling-up and obliteration of the costophrenic angle does inevitably tie down the dome.

Further the presence of dense interlobar adhesions, the outer edge of which are fixed to the chest wall and with the radiogram showing a curved outline convex upwards, is almost certain to act as a barrier guarding the upper lobe from influences below it.

---

* Read before the North-Western Tuberculosis Society on March 21st, 1935.

Indications for Paralysing the Diaphragm

It is essential, when considering the indications for paralysing the phrenic nerve, to appreciate the object of the operation. There seems to be a prevalent view that it is done for the cure of pulmonary tuberculosis. Profound disappointment must be the fate of those who operate under this misapprehension. Phrenic paralysis often relieves symptoms, especially when it has been correctly advised to this end rather than to the treatment of the disease, but it is not a radical operation for "cure." It is but an asset in the treatment of the disease. Used properly, it is an immensely valuable one, helping to overcome or to diminish mechanical changes which are interfering more or less seriously with the progress of recovery. Like other measures, it is an accessory to sanatorium treatment in the endeavour to increase the resistance of the body to the disease, the effective fibrosing of active tuberculous foci and the obliteration of cavities.

It is often stated that one of the indications for phrenic nerve paralysis is failure of artificial pneumothorax; in other words that a phrenicectomy should be done on every case on which an artificial pneumothorax has been tried and failed. It is possible that I have said this myself in the past, but I now assert emphatically that every case suitable for artificial pneumothorax is not necessarily suitable for phrenicectomy.

Artificial pneumothorax is attempted in cases of pneumonic tuberculosis and also in cases of the caseating, exudative form of disease. Possibly the immobilisation of the dome which has been paralysed may be advantageous in a purely basal case; but, if the base is not involved and is the comparatively healthy part of the organ, phrenicectomy is definitely contra-indicated, since it will bring about collapse of the healthy part of the lung and leave the diseased pneumonic area unaffected.

Then again, artificial pneumothorax is frequently done in the hope of collapsing cavities, usually in the upper lobe or apex. When these cavities are large or are surrounded by dense fibrous tissue, it is expecting almost the impossible to try to obliterate them by a phrenicectomy. The operation is useful for some cavities, but not for this type. Nor is a lung with old-standing fibrosis and one or more cavities likely to benefit by phrenicectomy. If the condition is unilateral, the indication is a thoracoplasty, in some cases without even the preliminary trial of an artificial pneumothorax. A phrenicectomy would be valueless and might even be detrimental.

The indications for phrenicectomy in the treatment of pulmonary tuberculosis are divisible into four groups:—

(1) For the treatment of pulmonary disease. In these cases the extent of the rise is the important factor.

(2) For the treatment of past or present pleural involvement. In this group both the rise and the immobilisation play an important part.

(3) For the treatment of symptoms. In these cases it is not so much the rise of the muscle as the loss of tone and the immobility that is necessary.

(4) In conjunction with other surgical measures.

THE PULMONARY LESION

The chronic fibrotic lesion is one of the types most responsive to phrenicectomy, but it is not all fibrotic lesions of the upper lobe which will respond to phrenicectomy. If the fibrosis is very dense and there are cavities, it will need a very exceptional rise of the dome to influence this, and even with such a rise, failure of an efficient collapse is more than probable. In such cases the cap of the lung is almost always firmly adherent and allows of no shifting of the lung surface; the whole of the collapse requisite to relax the fibrous tissue and to obliterate cavities would therefore have to be obtained by the upward displacement of the central part of the lung as a dome into the apex—an obvious impossibility. The probability therefore of a dense apical cap of adhesions and equally of dense interlobar thickening which acts as a barrier between the upper and lower segments of the hemithorax must be considered contra-indications. These cases, moreover, are eminently suitable for the major operations which will produce a permanent healing impossible by lesser measures.

A moderate degree of generalised fibrosis is, on the other hand, an indication for phrenicectomy. This type of case, even if the condition has been sufficient to produce some flattening of the chest wall and displacement of the mediastinum, may respond most favourably. It is in this group that is found pre-eminently the case which, having made considerable progress with rest in bed, reaches a stage with persistence of cough, sputum, and mild pyrexia beyond which it seems incapable of responding, but after a phrenicectomy improves again progressively and may become symptomless.

Cavities surrounded by dense fibrosis or with thick walls cannot be expected to be favourably influenced by phrenicectomy. Small cavities, on the other hand, without well-defined walls, whether in the base, apex, or region of the hilum, and which have resisted rest in bed, may become obliterated following on a fairly high rise of the dome. The possibility of success is certainly sufficient to justify the operation.

It must be admitted, however, that there are very divergent views on the value of phrenicectomy in the treatment of cavities. Patronikola,[1] for instance, says that out of 100 cases, 4 only were benefited. Russell[2] reports control in 9 out of 24 cases at the Cheshire Joint Sanatorium in which artificial pneumothorax had failed or been ineffective. The results of Nehil and Alexander[3] are very interesting: of 53 cases with a cavity of 2 cm. or less, closure occurred in 65 per cent.; of 63 cases with a cavity of 2–4 cm., closure followed in 36 per cent.; and in 32 cases with a cavity of 4–6 cm., closure occurred in 22 per cent. When the location of the cavity was in the upper third of the lung, closure was recorded in 40 per cent.; of those located in the middle third, 34 per cent. closed, and of those in the lower third, 29 per cent. closed.

Phrenicectomy has many advantages over artificial pneumothorax. It is a single operation and the risks of complications are infinitely fewer; if successful, it does not interfere with future work as may be the case with an artificial pneumothorax. It is pre-eminently the moderately localised proliferative lesion, whether of the upper or lower lobe, which has responded up to a certain stage, yet incompletely, to rest in bed, for which phrenicectomy is indicated as the first line of attack in preference to artificial pneumothorax. The operation should take precedence also in some cases of isolated thin-walled cavities, particularly when a cavity develops in the contralateral lung in a case under treatment by artificial pneumothorax. The combination of phrenicectomy on the one side and of artificial pneumothorax on the other may prove very valuable in the treatment of bilateral disease.

PLEURAL INVOLVEMENT

The second group of cases for which phrenicectomy is indicated is that in which an old or recent pleurisy has been responsible for thickening of the basal costal and diaphragmatic pleural membranes with obliteration of the costophrenic sulcus, and fixation and possibly distortion of the diaphragm. In these cases comparatively little immediate rise can be expected; nor is that the object of the operation so much as the paralysis and loss of tone.

The third group of indications is for the treatment of symptoms, a group far too often neglected. The first and most important, though not the commonest symptom which may call for an emergency phrenicectomy is hæmoptysis. Several cases have been recorded of intractable bleeding for which artificial pneumothorax had proved impossible but which have stopped abruptly after phrenicectomy; in some the bleeding came from the upper and in others from the lower lobe. Alexander gives preference to phrenicectomy over pneumothorax for the arrest of bleeding.

RELIEF OF SYMPTOMS

So far I have discussed the treatment of the disease. With healing there must naturally be improvement of symptoms, lessening of cough and sputum, pyrexia, disappearance of tubercle bacilli, and so on. The improvement in the cough and sputum may occur long before there is time for healing processes to take place. A working diaphragm is not necessary for bringing up and expelling sputum. Often as a result of the disease the dome moves but little, being in a state of tonic spasm, and this actually hampers expectoration. With paralysis of the dome, the full force of the contraction of the abdominal muscles is transmitted directly to the thorax, and facilitates expectoration.

Adhesions between the lung and diaphragm may cause a diaphragmatic cough—a spasmodic cough which is started by movement, laughing, even talking. This can be abolished by paralysing the dome, to the intense relief of the patient and with considerable benefit to the lung. The morning vomiting brought on by the pumping of the dome on the stomach with the initial emptying of the bronchial tubes of accumulated sputum after sleeping can also be stopped by a phrenicectomy.

Patients who have had pleurisy, whether the associated disease is still active or quiescent or healed, may experience dragging aches, pains, or discomfort round the base of the chest. The relief that can be given by paralysing the dome justifies the operation for this alone. Such pleurisies not infrequently implicate the pericardium, when the drag is liable to produce tachycardia on comparatively slight exertion. This too will be relieved by the relaxation of the dome.

AN ADJUVANT TO OTHER OPERATIONS

The final group concerns the indications for phrenicectomy in conjunction with other operative measures. The first to be considered is the combination with artificial pneumothorax. Reactions and effusions during the maintenance of artificial pneumothorax are more likely to occur and recur when there are adhesions which are stretched by each refill. Paralysis and rise of the dome may relax these bands and thus for the time being remove the irritation and lessen the tendency to reaction and effusion. If the adhesion is so placed that the tension is not relieved, no benefit will have been gained as regards these manifestations. Apart from this, phrenicectomy has no benign influence on effusions. It does, however, in certain cases undoubtedly enable the interval between refills to be lengthened.

The rise of the paralysed dome may aid somewhat in cases where the base of the lung is adherent or there is a progressive obliterative pleurisy. A high rise of the dome may be invaluable in certain cases of suspended cavity, converting occasionally an artificial pneumothorax which is a failure into a success.

When a lung, involved by a disease which produces fibrous tissue changes, has been long collapsed and is then allowed to re-expand, a considerable strain must be imposed on the originally diseased fibrotic area and on the walls of old cavities, when that lung re-expands. The hemithorax is admittedly smaller than at the onset, because the chest wall has shrunk and the mediastinum has come across, whilst the healthy alveoli have become emphysematous; yet it seems most advisable further to relieve the strain by raising the height of the dome by paralysing it.

Finally, there is the much debated question of phrenicectomy in conjunction with major operations. There are certain cases in which it is advisable to have the dome paralysed some time before the operation so as to help the cough and expectoration, reduce the pyrexia, and improve the general health of the patient. For these, a preliminary phrenic crush only should be done so that recovery of the function of the dome is returning approximately coincident with convalescence from the major operation. If a total thoracoplasty is indicated the motionless dome will, in my opinion, have a detrimental, rather than a beneficial, effect on the collapsed lung. When the operation is one localised to the apex or upper lobe, the raised dome is more likely to put healthy basal lung tissue out of action than to produce any appreciable collapse of the apex.

It is extremely doubtful if a paralysed dome has any influence in preventing an aspiration pneumonia during the operation. Its other supposed value as a test for the contralateral lung seems to me to be worthless.

The statement has just been made that a phrenic nerve crush should be done in preference to a phrenicectomy whenever the diaphragmatic paralysis is a prelude to a total or localised thoracoplasty or to an apicolysis. The phrenic crush is also the preferable operation in every case where the base of the lung is not affected and the influence on the lesion is of considerable doubt. It is also preferable in cases with bilateral disease when the operation is an emergency one to check bleeding. Matson[4] says that "a return of diaphragmatic function can be expected in 25 to 30 per cent. of all cases, unless all communicating or accessory fibres have been resected." Bonniot and Foix noted a return of function in 8 per cent. when the evulsed nerve was over 10 cm. in length, and in 29 per cent. when the length was under 10 cm. Lindberg[5] found that no improvement resulted when the total elevation of the paralysed dome was less than 3·9 cm. In 80 per cent. of his cases there was a secondary rise averaging 2 cm.; the maximum rise was usually not reached under three months. Matson records a case with an initial rise of 3 cm., a further rise of 6·5 cm. in the ensuing year, and a total rise of 13 cm. by the end of the second year.

Results

Many papers have been written and figures given showing the late results of phrenicectomy with the percentage "cured," improved, and so on. The general opinion is that considerable benefit can be obtained in suitable cases. Yet there are a few like Gravesen [6] who consider "that the actual efficacy of the operation has been greatly exaggerated by many," and that the indications are very limited. He finds that there were "only 27 cases (out of 153 available for 'true statistical analysis') where we have any right to say the patients were healed as the result of the phrenic operation." Those figures are, in my opinion (though not in Gravesen's), most encouraging, because I would again emphasise the fact that phrenicectomy must not be looked upon as a "curative" measure, but as an auxiliary and ancillary measure to other forms of treatment.

For this reason I make no attempt to give figures as to results. It is not possible to produce anything like an accurate statement. In some cases the operation is done with a certainty of benefit to be gained either as regards the disease or the relief of symptoms; in others there is a reasonable possibility of benefit. In yet others a crush is indicated as, while the result is doubtful, there is a possible hope of success. In a disease like tuberculosis, with its disappointments and surprises, this success must be sought for, at times even at long odds.

Complications

Berry [7] collected in 1930 the records of 4697 cases of phrenic nerve paralysis with a mortality of 26 cases. Of the deaths 6 were due to bleeding from extraction of the nerve and 2 to a traumatic emphysema and empyema associated with a traumatic pneumothorax. These 8 cases were unquestionably accidents associated with evulsion of the nerve. Lung embolus and œdema accounted for 3 deaths, and dyspnœa and heart failure for another 3. There were 12 deaths from pneumonia and tuberculous dissemination. Of these 12, 5 were reported by Loewenthal [8] who regarded the condition as an "unspecific pneumonia" due to injury to the pleura while evulsing the nerve. Another possible explanation is that during evulsion the dome gets drawn up into the thorax. At the moment that the nerve filaments give way the diaphragm returns with a sudden, violent descent which may easily cause the aspiration into the lower lobe of secretion squeezed out into the bronchi during the period of elevation. Death from syncope has also been recorded at the moment of evulsion. It is phrenic evulsion not phrenicectomy which is the operation which carries the immediate grave risks. I have seen 3 cases of spontaneous, symptomless, partial pneumothorax occur within a week of evulsion.

The most important of the later complications are those due to the displacement of the stomach and duodenum and the dislocation of the œsophageal opening. Vomiting occurs very occasionally immediately after paralysis of the left dome, but usually subsides in a day or two. Digestive disturbances, flatulence, and borborygmi may last somewhat longer. It is rare for these even to be serious in character or of lasting duration. The most troublesome complication in my series—and I am well on in my second thousand—has been the persistence of borborygmi for eight months, when it rapidly disappeared. Digestive discomfort has been recorded after paralysis of the right dome due to traction on the first part of the duodenum.

Radiological examinations show, according to Longuet and Launay,[9] that with a high rise of the left dome the stomach is elongated and shows a large air space. Of more serious consequence is, however, the condition similar to that found with eventration of the diaphragm, a rotation, producing a partial volvulus of the stomach, causing a constriction across the length of the organ.

Symptoms may therefore be produced by constriction of the œsophagus, of the stomach, or of the duodenum. In the majority of the cases the symptoms are slight and transitory. Very rarely only are they of serious import, and they may then be associated with cardiac or pulmonary manifestations, such as tachycardia or dyspnœa. Dyspnœa of a mild grade may also be observed independently of the above complications. It may persist for two or three weeks and then subside as compensation and adjustment take place.

CARDIAC HYPERTROPHY IN EXPERIMENTAL NEPHRITIS

By J. B. Duguid, M.D. Aberd.

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY IN THE WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF

The occurrence of cardiac hypertrophy in the course of an experimental nephritis which is tubular in origin seems to open the way to some new conceptions of the relationship between nephritis and vascular disease.

Gough, Duguid, and Davies (1933) reported the production of a renal lesion in rats by the oral administration of large amounts of orthophosphates in conjunction with overdoses of vitamin D, and the lesion was further described by me in 1934. It is a greatly intensified form of the phosphate nephritis described by Hirsch (1923), and by MacKay and Oliver (1930). Besides becoming chronic and progressive, and producing in some cases extreme disorganisation of the kidney, it has certain important features of interest. For example, although it is primarily and essentially a tubular nephritis, it may in its more advanced stages develop glomerular, and even arterial changes, very similar to those found in man, and it may also lead to a pronounced cardiac hypertrophy.

The lesion can be readily produced in rats by feeding them for 20–30 days on a diet of bread and potatoes, to which has been added acid sodium phosphate (5 parts per hundred, by weight), and at the same time administering a daily dose of 20,000–40,000 units of vitamin D by mouth, in the form of calciferol. At the end of the period of treatment the rats may be put on a normal diet and allowed to recover. They may survive for many months, and most of them develop a chronic nephritis which tends to progress in severity, long after the treatment has been stopped.

The primary lesion is a parenchymatous degeneration, in which focal calcification of the tubules figures prominently. This is followed by a gradual and progressive destruction of entire tubules. Many atrophy and disappear, whilst others dilate and become cyst-like (Fig. 1). Large areas of shrinkage form in the cortex, so that the kidney becomes extremely distorted, with its surface pitted and granular. In most cases the glomeruli remain intact, but in a few of the more severe ones, they undergo changes of an apparently toxic nature. These changes vary, but they usually take the form of hyaline swelling of the capillary membranes, and gradual hyaline transformation of the whole renal corpuscle, similar to that seen in the so-called primary interstitial or primary ischæmic nephritis of man. The endothelial cells of the tufts gradually disappear. Later the whole structure becomes fibrosed and obliterated. When the glomeruli are affected, the arterioles may also be involved. Their walls become thickened and hyaline, and finally when the glomeruli are destroyed, the vessels also become obliterated. It should be noted that no direct relationship seems to exist between the glomerular lesions and the tubular degeneration in this nephritis. The glomeruli may remain intact in the midst of extreme tubular destruction, and when they do degenerate, the degeneration appears to be the result of some additional toxic factor, rather than of the tubular destruction itself. Nor is there any evidence that the glomerular degeneration is the result of vascular disease. Such vascular changes as arise invariably appear to be a later event, and seem therefore to be a result rather than a cause of the glomerular degeneration.

In some of the long-standing and severe cases, changes may also be found in the arteries, especially in those parts where the parenchymatous shrinkage is most intense. Here the smaller interlobular arteries may appear narrow and tortuous, sometimes giving the impression of hypertrophy, but without any degenerative change in their walls. There seems to be little doubt that this change represents a simple contraction. The atrophy which occurs in this disease causes great shrinkage of the tissues, and this must bring about a considerable reduction of the capillary field. Some reduction of the arterial supply is apparently called for, and the changes which occur in the arteries are probably to be regarded as something in the nature of a functional readjustment. One or two of the most long-standing cases have shown some fibrous intimal thickening in addition, but this is a comparatively rare finding.

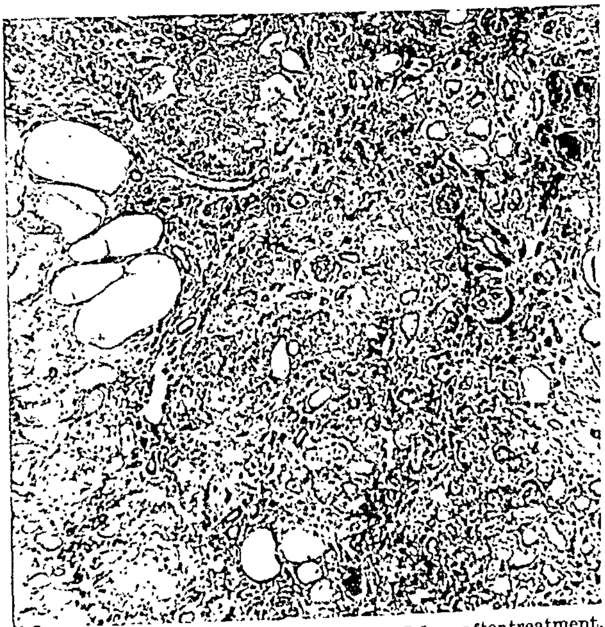

FIG. 1.—Kidney of a rat which survived 67 days after treatment. (× 50.)

It is only in the severe cases, which survive for two or more months after the treatment, that cardiac hypertrophy is found. It takes the form of concentric thickening of the left ventricle very similar to that seen in man. Sometimes the heart increases to more than double its normal weight. Fig. 2 shows hearts of six of the most severe cases, compared with those from normal rats of the same weight. In a group of experiments recently carried out, 160 rats were treated in the way specified above, and 98 of them survived the treatment for more than one month, the rest having died, or having been killed in the early stages, for the purpose of investigating the initial lesion. Of the survivors, 85 showed well-marked chronic lesions, and 23 of them were classified as showing histologically intense nephritis, Fig. 1 showing a typical example. The hearts of these 23 cases were weighed after fixation in formalin. Expressed as percentage of the body-weight they averaged *0·73* with standard deviation 0·15, and extreme range from 0·46 to 1·06. The comparable figures from 60 normal rats were: average *0·43*, S.D. 0·09, and extreme range 0·26 to 0·66.

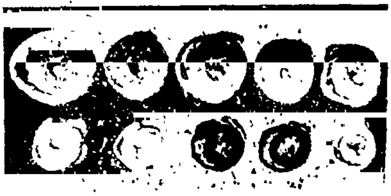

FIG. 2.—The upper row of hearts are from nephritic rats. Those below are from normal rats, each of the same body-weight as the corresponding one above.

These figures become even more striking when calculated in relation to the two-thirds power of the body-weight (i.e., blood volume). For the 23 extreme cases they read: average *3·89*, S.D. 0·78, range 2·57 to 5·21; and for the normals: average *2·18*, S.D. 0·29, range 1·56 to 3·27.

In these 23 rats the amount of glomerular change was variable—in some cases very inconspicuous—whilst well-marked arterial changes were present in less than half of them. Thus, although these figures show beyond doubt that this experimental nephritis in rats has effects on the heart similar to those seen in chronic nephritis in man, they show no evidence that arterial disease is concerned in the process. The cardiac hypertrophy is clearly the result of the parenchymatous destruction, and if an explanation on the lines of vascular disturbance has to be offered, the most likely one would seem to be that the disturbance of renal function produces toxic substances which affect the heart through alterations in the blood pressure.

In man, cardiac hypertrophy is usually regarded as one of the consequences of the underlying arterial disease from which the nephritis itself is supposed to arise. It thus forms part of the basis of the vascular theory of nephritis. The findings in rats are of interest because they call for an entirely different interpretation. In view of them, the possibility of a chronic nephritis with glomerular, arterial, and cardiac changes arising from a primary tubular nephritis has to be considered.

RESECTION OF THE RECTUM WITH RESTORATION OF CONTINUITY

By Charles A. Pannett, B.Sc., M.D. Lond., F.R.C.S. Eng.

SURGEON TO ST. MARY'S HOSPITAL; PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON

In all the older text-books of surgery Kraske's operation for resection of the rectum is described. It is essentially an excision by a sacral approach between the anus and the third piece of the sacrum itself. Originally it was devised so that after resection continuity of the bowel could be restored, but in practice it was frequently found that this was not effected. Either there was too much tension or the blood-supply of the upper segment of the bowel had been so damaged that no repair was possible. Gangrene, followed by an incurable sacral fistula, was the ultimate result. Hence in many cases the operation was completed, not by restoration of continuity, but by the deliberate formation of a sacral anus. In this region the inconvenience of an artificial anus is so great that it is not surprising to find most surgeons abandoning it for the usual iliac colostomy.

The immense advantage of an abdominal anus, combined with a quite erroneous conception of the mode of spread of carcinoma of the rectum, have led to the adoption of two operations for this disease in this country to the exclusion of all others—namely, the perineal and the abdomino-perineal, or lately the perineo-abdominal. It is fair to say that, except for one or two independent advocates of sphincteric preservation, notably Prof. Grey Turner,[1] the English surgeon has been obsessed by the opinions of those writers who, without observational justification, have insisted upon the necessity in every case of sacrificing the whole of the bowel below a carcinomatous growth, together with all the fat and pararectal tissue in the ischiorectal fossæ. The objectionable qualities of any artificial anus have been allowed conveniently to sink into the background. Some accounts would make us believe that a man with an iliac colostomy, when properly performed of course, suffers from little, if any, disability or inconvenience; we are almost persuaded that it is an advantage. Such adulatory accounts, however, always come from the surgeon. I have yet to meet a patient who contemplates with complete satisfaction and equanimity his possession of an artificial outlet for his fæces. The waste of time each morning in emptying his colon that he may pass the remainder of the day in comparative comfort, the ever-present possibility of involuntary escape of solid or gaseous contents, the constant attention to his diet are not trivial matters. The revolting nature of these daily attentions is extraordinarily disturbing to a man of culture and refinement, and is apt to induce a most unpleasant state of mind, a condition which may best be described as a stercoral outlook on life. No normal man could contemplate a colostomy with anything but dismay.

Twelve years ago an educated woman with carcinoma recti came to see me. She knew the nature of the disease and the operative implications had been explained to her. She refused to consider for one moment a colostomy and begged me to avoid one or do nothing. This was the first case in which I performed a sacral excision of the rectum with restoration of continuity. It was a complete success so far as local removal went, but the patient succumbed some two years later to a metastasis in the liver. Since then I have carried out the operation with what must be considered, when results are taken into account, a quite discreditable infrequency. It is the realisation of this delinquency which leads me to urge a more extensive trial of the method, particularly as recent pathological investigations afford a complete justification for disregarding the alleged necessity for extensive removal of the perirectal tissues.

Pathological Considerations

These pathological investigations are due particularly to Westhues and Schmieden in Germany,[2] and to Cuthbert Dukes in this country. The essential facts are few and simple. Lymphatic flow from the rectum is preponderatingly—one may with some justification say, exclusively—in an upward direction along the course of the superior hæmorrhoidal vein, up into the glands of the mesosigmoid, and thence into the aortic glands. No lymph travels laterally to the walls of the pelvis and none passes downwards and out to the inguinal glands unless the growth encroaches actually upon the anal canal. Only the glands in the mesosigmoid need concern the operator, but it is essential that the tissue behind the rectum in the hollow of the sacrum be effectively removed.

A second pathological fact of very great importance is the recognition of the small part that local permeation in the actual wall of the rectum takes. The bowel is quite free from carcinoma cells 1·0–1·5 cm. below the macroscopic margin of the growth; a somewhat wider margin may be required above. Sometimes in more advanced cases a blunt-shaped process grows right through the rectal wall more frequently posteriorly or slightly to one side. This mass is in continuity with the main growth and usually inclines orally along the bowel. Never in specimens obtained at operation does it extend through the visceral layer of pelvic fascia which lies behind the rectum. The corresponding process in front either pushes the peritoneum of the fold of Douglas upwards or grows through it forming the umbilicated appearance in this region familiar to all surgeons. The part played by the pelvic fascia in limiting the spread of carcinoma is very important, and its bearing upon operative procedure will be referred to again. It may be noted here that whilst it is an almost certain barrier behind it is not quite so impenetrable where it forms the recto-vesical layer in the male. Occasionally in an operable stage, growth will have invaded the prostate. It is very rare to find it encroaching actually upon vaginal tissue. Carcinoma of the anal canal is not so confined by facial layers; it spreads easily into the perirectal tissues. It is much more difficult to eradicate locally.

Anatomical and Operative Considerations

It is clear that to make an effective removal of a growth above the anal canal it is not necessary to take away much of the rectum above and below the apparent margin of the carcinoma. It is quite sufficient to cut the bowel across 1·5 cm. below the growth with the assurance that no cancer cells will remain behind. Above, it is advisable to take away 1·0 cm. more. The tissue in the neighbourhood of the middle hæmorrhoidal vessels is innocuous and should be left, but free removal of the tissues behind the rectum extending up the whole extent of the mesosigmoid is absolutely essential for success.

The visceral layer of pelvic fascia, being a natural barrier to the spread of the growth, it is wise to keep outside this layer as far as is possible. It arises, it will be remembered, from the white line at the side of the pelvis and passes medially upon the upper surface of the levator ani and coccygeus towards the rectum, seminal vesicles, prostate, and bladder. Reaching these viscera it spreads out over them and between them, the strongest septum being that separating the prostate from the rectum. In dissecting the rectum from the prostate in front by the sacral approach, the visceral layer must be incised longitudinally on each side of the rectum anteriorly. This fascia is disclosed as a glistening membrane almost like peritoneum after the levatores ani have been divided close to the bowel. Unless it be incised in this manner it is difficult to find the proper interval. The separation takes place actually behind the thick septum between the rectum and prostate. If the fascial investment of the rectum be traced downwards it will be found to be reflected laterally on to the upper surface of the pelvic muscular diaphragm, as described above, and behind to be reflected on to the anterior surfaces of the coccyx and sacrum. It thins off as it is traced upwards to the promontory of the sacrum and the first lumbar vertebra, where it disappears as a distinct layer. It is between this layer of fascia and the peritoneal reflection on to the sides of the rectum and pelvic colon that the lymphatic glands and tissue lie which must be removed in the operation for carcinoma. The middle sacral artery lies on the outer surface of this layer of fascia sometimes adherent to it. The superior hæmorrhoidal artery should be ligated at the safe point above the origin of the lowest sigmoid branch. This will be accomplished if the artery be tied just above the promontory of the sacrum or at a higher level. At the point where the lower section is made in removing a growth the rectum has no peritoneal investment.

The Choice of Operation

There are two ways in which a resection may be carried out, by a sacral approach or by a combined abdominal and sacral method. The Goetze operation based on the above considerations is adequate and effective. It may be briefly described.

SACRAL RESECTION BY GOETZE'S METHOD [3]

With the patient in the left lateral position, a median incision from just behind the anus to the middle of the sacrum is made. The coccyx and the sacrum below the third pair of foramina are removed. Deep to them will be found the sacrum invested with the visceral layer of pelvic fascia in the outer layer of which runs the middle sacral artery. This fascia is easily stripped off the hollow of the sacrum up to the promontory allowing the rectum to fall forward. The pelvic fascia is divided longitudinally about the level of the middle of the sacrum at 3–4 cm. to the right of the left lying rectum. Underneath will be found the loose fat of the extraperitoneal tissue which is easily pushed aside to expose the peritoneum itself. This is opened here. A similar dissection to the left but closer to the bowel will open the peritoneum on that side. The rectum is now pulled downwards and forwards to stretch the tissue lying behind it in which lies the superior hæmorrhoidal artery. This vessel is divided between two ligatures at the level of the promontory. When this is done the gut is immediately liberated and comes down with a jerk. It is now quite easy to join the two side openings in the peritoneum across the rectovesical pouch and to separate the rectum from the strictures in front working from above downwards. This separation lower down will be facilitated by bearing in mind the anatomical points mentioned above.

When the growth has been separated above and below it can be excised and an end-to-end suture carried out as described later. If it should be found impossible to bring enough of the intestine down for this purpose Goetze recommends that the upper end be sutured in the posterior wound; this is a weak point in the procedure. Another weakness is that it is not possible working from below to assure oneself of the state of the blood-supply of the upper segment of bowel. Again, if the growth has pushed up the peritoneal reflection or penetrated the rectovesical pouch the difficulties are immensely increased. Moreover, we remain quite in the dark as to the presence of other metastases in the abdomen. For these and other reasons a combined abdomino-sacral operation is much to be recommended.

THE ABDOMINO-SACRAL RESECTION

I have not performed this operation many times, but its advantages appear to me to be so great that I do not hesitate to recommend it. With the abdomen open it is possible to inspect the condition of affairs *from above (see, Figure)*, *particularly* any *spread* of the growth to the peritoneum, and the size of any metastases in the lymph glands. Though umbilication of the rectovesical fold is not an absolute contra-indication to excision the spread of the growth in these cases is always extensive. A bowel apparently fixed to the sacrum is often easily separated with its investing visceral pelvic fascia. Very important is the ease (unless the patient be too fat, when the wisdom of this operation is doubtful) with which the point for ligature of the superior hæmorrhoidal artery may be selected so as to preserve the blood-supply of the rectum; also the line along which the mesocolon should be divided to allow of a piece of bowel being brought down without tension to make the anastomosis. When the abdomen is opened it can be seen at once if a resection with restoration of continuity is precluded because of an unusually short mesosigmoid. Under such circumstances there must be made an inguinal colostomy and sometimes the operation of removal of the growth may be completed wholly from above.

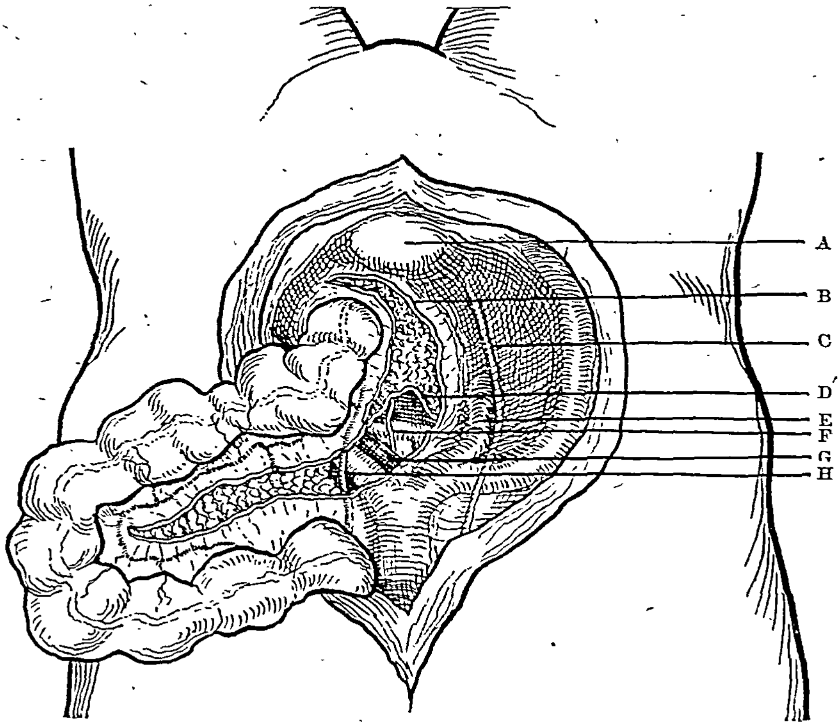
The objection to the ordinary abdomino-perineal excision of the rectum is that it is productive of much surgical shock does not hold for the abdomino-sacral operation. My experience with this and the purely sacral excision is that shock is much less when the sphincteric region of the rectum is not interfered with.

The steps of the operation are simple enough.

When the abdomen has been opened and the operation deemed to be feasible, the peritoneum of the mesosigmoid is incised at a point in the neighbourhood of the apex of the sigmoid loop so situated that the important arterial arcades remain between it and the margin of the bowel. Thence the incision proceeds to the promontory of the sacrum, then along the root of the mesosigmoid, around the floor of the pelvis, and across the rectovesical pouch to join a similar incision on *the other* side of the pelvis. The only difficulty in this is the depth at which the incision is made and the narrowness of the pelvis. It may be facilitated by dragging forwards with suitable forceps the bladder in the male or the uterus in the female. The superior hæmorrhoidal artery is then ligated and divided at the safe point about a centimetre above the promontory *of the sacrum*. The *fatty* tissue of the mesosigmoid is divided towards the bowel wall corresponding with the peritoneal incision. By a little careful dissection just below the sacral promontory it will be found possible to strip the hollow of the sacrum free, keeping behind the visceral pelvic fascia down as far as the tip of the coccyx. At the side the upper margin of the levator ani is passed. It does not seem necessary always to dissect out the ureter, but if there is any uncertainty about its position this may easily be done. At the sides of the rectum low down is the pelvic fascia which must be cut to free the bowel. No hæmorrhage of any consequence occurs in this situation. In front, separation from the vagina or bladder, seminal vesicles, and prostate is not so easy. It cannot be done here altogether by blunt dissection or with the fingers. The help of scissors is required.

When the rectum has been separated on all sides as low down as possible, by trial, the upper point of division of the colon is selected so that it will extend easily down to the distal stump. When this has been done the mesosigmoid must be severed to this point at such a distance from the bowel margin that the necessary arterial arcades are preserved. This is one of the great advantages of the abdomino-sacral route.

The separated bowel is now pushed down into the pelvis whilst the peripheral margin of the peritoneum is sutured around it and to the mesosigmoid so as to shut off the abdominal cavity completely. The abdominal wall is sewn up. With the patient on the left side with the knees drawn up, an incision is made from just behind the anus to the posterior aspect of the lowest part of the sacrum. The coccyx only need be removed—another advantage. It is usually quite easy then to deliver the separated growth, rectum, and lower part of colon. Some dissection is needed to detach the rectum in front. It is carried out by dividing the levator ani on each side about 1 cm. from the median line but only so far downwards as is absolutely necessary. The glistening pelvic fascia beneath this is divided longitudinally on each side just behind some vessels which can usually be seen through it and mark the prostatic plexus or at a similar place in the female. Only 1·5 cm. of rectum below the growth need be removed. The upper section takes place at the already selected point. The intervening portion includes all the tissue behind the rectum up to the sacral promontory as well as the growth itself. This is all that it is necessary to remove. The anastomosis is performed in the usual manner in two layers, the anterior aspect being done first.



Parts displayed in the abdominal stage of the resection: (A) bladder, (B) peritoneum, (C) ureter, (D) visceral layer of pelvic fascia, (E) internal iliac artery, (F) middle sacral artery crossing promontory of sacrum, (G) common iliac vein, (H) superior hæmorrhoidal artery.

Although I have taken the usual precautions to protect surrounding tissue with sterile cloths, I have never got primary union without a fæcal fistula for at least a few days. It is essential to pass a tube up the rectum past the anastomosis. Although its use can be dispensed with I do not recommend that this should be done. In one of my patients intestinal obstruction came on; she was much distended and had severe colic with vomiting, which was relieved immediately by the passage of a rectal tube. Evidently the colonic portion may suffer temporarily from a physiological obstruction. Drainage must be provided for from the posterior sacral wound. Although some suppuration always occurs I have not yet had a persistent fæcal fistula.

Some surgeons fear a stricture at the site of the anastomosis. The following observation is of interest in this connexion.

In one man I felt that a preliminary colostomy was desirable because of obstruction. When this has to be done I think the second stage should be a purely sacral operation, though I am not sure that it would be altogether unsafe to do the combined operation provided an efficiently large drainage-tube be passed through the anus past the anastomosis. However in this particular man a sacral resection was performed. It resulted in a stricture which would not quite admit the middle-joint of my index-finger. Every two weeks it was digitally dilated for one year but no progress was made. At this time the patient begged me to close his colostomy, which I did. To my surprise no difficulty from the stricture was experienced, and three months later the stricture had dilated up purely by natural use so that, to the finger, it was almost imperceptible.

I have no large series of such operations to report, but those I have done have been extremely satisfactory. The condition and happiness of the patients is incomparably better than if a permanent colostomy had been made. It is with the hope that the operation will become more general that this communication is made. It deserves a wider trial, it is based upon sound pathological observations, it results in a normally constituted individual, it is not difficult to execute, and it does not seem to be associated with great shock.

FIRST AID BY PARACHUTE.—It is announced that several doctors and nurses at the Botkinski Hospital in Moscow have pledged themselves to learn parachute jumping. Their intention is to attend urgent medical cases in remote areas where there are no suitable landing places for aeroplanes.

RHEUMATIC HEART DISEASE AND VITAMIN C

BY C. BRUCE PERRY, M.D. Brist., M.R.C.P. Lond.
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BRISTOL

IN 1933 Rinehart and Mettier[1] described changes in the joints and heart valves of scorbutic guinea-pigs when infection was superadded to the vitamin deficiency. Somewhat similar changes on a much smaller scale were found in some animals with uncomplicated scurvy, but infection alone produced no such changes. These authors were struck by the similarity of these pathological changes to those of acute rheumatism. Further investigations[2,3] supported the original observations, and they suggest that rheumatic fever may be the result of the combined influence of scurvy and infection. In a discussion of the known facts with regard to the ætiology of acute rheumatism in childhood, Rinehart and Mettier point out that the theory that vitamin-C malnutrition may be a factor in its production might explain much of the curious social incidence of this disease. The possibility of the existence of "subclinical scurvy" amongst apparently normal children has been raised by the work of Göthlin[4] and others (Dalldorf[5] and Stocking[6]). All these investigations are based on the "capillary resistance test" or Rumpel-Leede phenomenon. The test was originally described by Rumpel[7] and Leede[8] as occurring in scarlatina and consists in the artificial production of skin petechiæ by placing a tourniquet on the arm at varying pressures below the systolic blood pressure and thus producing venous congestion. In 1914 Hess and Fish[9] described this test in infantile scurvy but they stated quite definitely that "the capillary resistance test is brought forward not as a specific test for scurvy but rather as a method of bringing to view a weakness of the vessel walls whatever may be the cause."

The assumption that a decreased "capillary resistance" is an indication of subclinical scurvy in apparently healthy people is, therefore, open to much criticism. Hess[10] has recently again stressed the fact that the capillary resistance test should not be taken in any way as a criterion of vitamin-C deficiency, and Greene[11] has been forced to the same conclusion. Although the evidence for the existence in the general child population of subclinical scurvy is very insecure it appeared desirable to investigate rheumatic children for any evidence of vitamin-C malnutrition in view of Rinehart and his colleagues' conclusions and suggestions.

THE INVESTIGATION AND ITS RESULTS

Harris and Ray[12] have described a test for vitamin-C deficiency based on the excretion of ascorbic acid in the urine after the administration of a test dose of vitamin C. The test was carried out as follows:—

> At 6 A.M. 500 mg. of synthetic ascorbic acid was given in water by mouth and the urine was collected at two-hourly intervals for 12 hours. The urine was measured as soon as passed and made acid by the addition of 10 per cent. by volume of glacial acetic acid. The estimations were carried out as soon as possible, and always within six hours. 0·05 c.cm. of a 0·05 per cent. solution of 2 : 6 dichloro-phenol-indophenol (equivalent to 0·01275 mg. ascorbic acid) was taken, and the amount of acidified urine required to decolorise this determined. If less than 0·02 c.cm. of urine was required the urine was diluted with a 10 per cent. solution of glacial acetic acid.

This test has been criticised by Parsons[13] on the grounds that ascorbic acid is not the only substance that occurs normally in the urine which reduces the dye used (2 : 6 dichloro-phenol-indophenol). If the criticism is correct it does not invalidate the value of the test since it is the increase in the vitamin-C excretion following a test dose that is important, and this may reach some ten times the basal output. Five cases of active rheumatic heart disease and six quiescent cases have been studied by this test (see Table).

TABLE SHOWING ACTIVE CASES

A.A. =Ascorbic acid excreted in urine in 12 hours after test dose of 0·5 g. (in mg.).

C.R. =Capillary resistance (Göthlin). Number of petechiæ after tourniquet at 50 mm. Hg for 15 minutes.

E.S.R. =Erythrocyte sedimentation-rate. Fall (in mm.) at the end of one hour in a 10 cm. column of blood.

	Sex.	Age.	Date in 1935.	A.A.	C.R.	Clinical condition.	E.S.R.
1	M	14	Mar. 19	A.A. given but urine not collected by mistake.	0	Fifth day of first attack of rheum. fever, arthritis, and pericarditis.	22
			Mar. 21 Apr. 16 (*a*)	6·5 142	3	April 3 : fresh rise of temp. with pericardial rub which persisted till April 18.	47
2	M	12	Mar. 21	48 (some urine lost)	1	Rheum. heart dis. Acute relapse with arthritis and pericarditis.	50
3	F	9	Mar. 28	99	0	First attack of rheumatism, fever, arthritis, and carditis.	45
			Apr. 16 (*b*)	118	0	April 18 : relapse with fresh fever and increase in cardiac physical signs.	51
4	F	15	May 17 May 18*	9 9·7	0	Chorea and carditis three weeks after tonsillitis and otitis media.	50
			May 28 (*c*)	146	0	Chorea less and cardiac physical signs decreased.	20
5	M	12	July 15	77	4	Rheum. heart dis. Acute relapse, with fever, arthritis, and carditis (partial heart block).	54
				QUIESCENT CASES			
6	F	14	Mar. 18	196	2†	Rheum. heart dis. No clinical evidence of activity.	3
7	M	12	Mar. 19	60 (some urine lost)	0	Old chorea and rheumatism. No clinical evidence of activity.	5
8	M	17	May 28 May 29*	8·5 7·4	2	Rheum. heart dis. No clinical evidence of activity.	3
9	F	14	May 28 May 29*	13·6 24·4	1	Rheum. heart dis. No clinical evidence of activity, slight attack of chorea in April.	5
			June 17 (*d*)	341	0		4
10	M	11	May 30 May 31*	5·5 10	1	Rheum. heart dis. No clinical evidence of activity.	4
			June 1*	78			
11	F	10	June 15	77	8	Rheum. heart dis. No clinical evidence of activity.	3

(*a*) After 26 days' full diet.
(*b*) After 19 days' full diet.
(*c*) After 0·5 g. ascorbic acid daily for 8 days.
(*d*) After 0·5 g. ascorbic acid daily for 15 days.
* Repeat test.
† Twenty days previously while menstruating 40.

Of the five active cases three showed a marked rise in the excretion of ascorbic acid following the test dose, and were thus presumably in no way deficient in this vitamin. Two cases showed no response despite the repetition of the test, in one case on the next day and in the other after one day's interval. One of these children was given 0·5 g. ascorbic acid daily for 8 days and then retested when there was a large amount excreted. The other was retested after 26 days on a full diet and showed a normal response. It is interesting to note that just before the second test this child suffered an acute rheumatic relapse. All of these cases had a normal capillary resistance as judged by Göthlin's standards.

Of the six quiescent cases three showed a satisfactory rise in the excretion of vitamin C after the test dose. One of these cases gave a positive capillary resistance test (8 hæmorrhages in a 60 mm. circle at the bend of the elbow after a pressure of 50 mm. Hg for 15 minutes). Another, 14 days before the test, while menstruating, had a much impaired capillary resistance (40 hæmorrhages after 50 mm. Hg pressure for 15 minutes) but at the time of the test this had returned to within normal limits (2 hæmorrhages). (Vogt [14] has shown that there may be decreased capillary resistance at the onset of menstruation.) In one case there was no response to the first and second test but the repetition of the dose of vitamin C on three consecutive days finally lead to a satisfactory excretion. The capillary resistance in this case was normal. Two cases showed no response to the test dose of ascorbic acid even although the test was repeated on the following day. Both of these children also had normal capillary resistance. One of these two received 0·5 g. of synthetic vitamin C daily for 15 days at the end of which time the test showed a very large excretion of vitamin C. Thus of the active cases two, and of the quiescent cases three, showed evidence of vitamin-C malnutrition.

These findings afford no support for the theory advanced by Rinehart and Mettier that vitamin-C deficiency plays an important rôle in the causation of acute rheumatism. This is in accord with Faulkner's [15] observations that the administration of large doses of vitamin C failed to affect the course of rheumatic fever, although the same author found that cases of rheumatic fever developed a slight reticulocytosis, analogous to that seen in the anæmia of scurvy but on a much smaller scale, following the administration of the vitamin. Faulkner from his studies concludes that any infection may increase the demand for vitamin C and that deficiency may develop secondarily, but that deficiency of vitamin C is *not a factor in the ætiology* of rheumatic fever. Warner and Winterton [16] have come to the same conclusion from a dietetic study of rheumatic children. While this investigation casts doubt on Rinehart and Mettier's suggestions and also on the claims of those who regard the capillary test as a delicate index of vitamin-C deficiency, since all these cases showing evidence of unsaturation with vitamin C had normal capillary resistance tests, it does suggest that some degree of vitamin-C deficiency is not uncommon amongst children with active and quiescent rheumatic carditis.

CONCLUSIONS

(1) Vitamin-C deficiency is not an important factor in the causation of acute rheumatism. (2) Mild degrees of this deficiency are not uncommon in rheumatic children. (3) The capillary resistance test is not a reliable guide to this deficiency.

Thanks are due to the sisters and nursing staff of the Bristol Children's Hospital and Bristol General Hospital, without whose assistance in collecting the urinary specimens this investigation would not have been possible.

Clinical and Laboratory Notes

INCONTINENCE OF FÆCES IN A YOUNG GIRL

By J. Hartsilver, M.R.C.P. Lond.

A GIRL 8 years of age was brought to me on June 11th, 1935, with the complaint that she was unable to control her motions and had been continually soiling her clothes and bed for three weeks, by which she was much distressed.

About three actions occurred during the 24 hours, and the child was occasionally conscious of the act. There was slight loss of weight, appetite was poor, and she had occasional bilious attacks. A year previously the patient had come from India where she had enjoyed good health. Before the trouble began both she and her sister had been treated elsewhere for warts by means of carbon dioxide snow and the electric cautery, and it was stated that "both children suffered great pain and were terrified of the treatment." As a rule they were not easily frightened, having been brought up in the "wilds."

Examination.—A healthy, well-nourished girl, very alert, and bright mentally. Eyes, tonsils, and teeth, nothing abnormal found. Tongue coated with fur, breath heavy. Neck, chest and abdomen, perineum and rectal examination: nothing abnormal. Motions: dark and formed; no thread-worms seen; no signs of other parasites. Reflexes (upper and lower extremities and epigrastic) normal; no ankle-clonus. Urine: acid; specific gravity, 1013; no albumin or sugar; acetone ++ in two examinations. No signs of rheumatism.

Progress.—Shortly after this examination chicken-pox developed. Bed and a milk diet were suggested to the mother, and the girl was asked to pass her motions at regular periods, three times a day. When conscious of the act she was to try to stop defæcation till she was able to use a chamber. She readily agreed to do this. Potassium citrate was given for the "acidosis." Recovery was almost immediate and uneventful.

It should be mentioned that the younger sister was also upset by the treatment for warts but did not suffer in any other way.

Assuming a maximum incubation period of 21 days for chicken-pox, there is a remote possibility that the incontinence was due to an associated infection of the central nervous system; but there were no signs of this uncommon complication. There remains the definite history of the fright and nervous upset from the carbon-snow treatment.

When associated with enuresis, fæcal incontinence is usually confined to the daytime, whereas enuresis, if not occurring throughout the 24 hours, is nocturnal only. Causes enumerated in the text-books include extreme asthenia in severe illness, impending death, extreme fear, collapse or shock, and central nervous disease such as poliomyelitis, spina bifida, paraplegia from myelitis, or damage to the brain or spinal cord; also damage to the nerves or muscles of the pelvic floor. As a rule however the condition is clearly functional in origin, since almost all the children affected are highly nervous, often suffering from night terror, insomnia, stuttering, or habit spasm. It may also be associated with rheumatism. Other causes are said to arise locally—intestinal disorders, threadworm, and colic or weak or dilated sphincter. The condition should, I think, be distinguished from "constipation with incontinence" as described by Thorling, Bloch, and D. Hubble,[1] which seems to be primarily due to overflow from an overloaded rectum. Here also, however, there must surely be a nervous factor in operation, since loaded rectums are common, but reported cases of constipation with incontinence are evidently extremely rare. In my own patient no constipation had been noted before the onset of the incontinence (which was comparatively abrupt), and fæces were not found in the rectum.

In treatment Still[2] advises Dover's powder grs. $1\frac{1}{2}$–3, according to age, and belladonna, bromides, and arsenic; also a diet avoiding foods likely to irritate the bowels such as fruit and vegetables.

I am indebted to Dr. A. Blair Griffiths for permission to write this note on his patient attended during his absence.

Hove, Sussex.

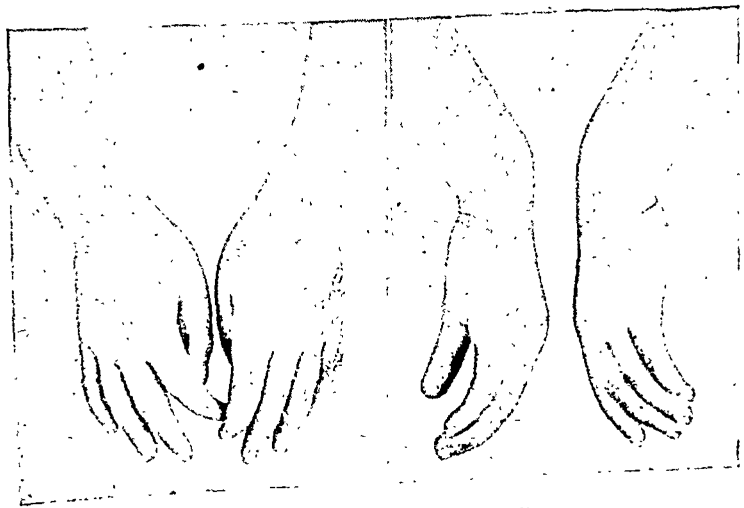
MADELUNG'S DEFORMITY

By Sami Barsoum, M.D.

OF THE AMERICAN MISSION HOSPITAL, ASSIUT, EGYPT

A girl about 12 years old came to our free clinic on April 4th, 1935. It had been noticed about a year before that she had no strength in her hands and would drop things that were at all heavy. It was also noted about that time that there was abnormality in the shape and mobility of the wrists, which are very weak. The accompanying photographs show the conspicuous volar displacement of both hands and carpal regions, with abnormality in the mobility of the two wrist-joints. The deformity is almost or entirely symmetrical in the two wrists. There is some pain with forced movement of the joints. Abnormal curvature of the radii may also be observed with apparent thickening distally and an unusual carrying-angle of the forearm.

The case was referred to Dr. Giffen, director of X ray and laboratory department, and his films helped in the diagnosis of Madelung's deformity. Other joints and bones of the body seem to be normal, though no radiological examination has been made beyond the forearms and hands.



Photographs showing the deformity.

RUPTURED URETHRA

AN UNUSUAL ACCIDENT AT SEA

By H. C. Hopkinson, M.A. Camb., M.R.C.S.Eng.

While acting temporarily as ship's surgeon on the North Atlantic run, the following case came under my care.

We were two days out from St. John, New Brunswick, homeward bound; the weather was stormy from March gales, and the decks slippery from constant spray. A young Scotsman, aged 20, while running across the deck, slipped, lost his balance, and slithered at considerable speed against the iron upright of some railings before the after-hatch. His position was such that he collided with the iron stanchion with his legs apart, one on either side of it, so that he received the full force of the blow on his perineum.

The young man was tough and plucky, and took no notice of the accident until two hours later, when, on attempting to pass water, he found that he was unable to do so, and that there had been a considerable oozing of blood from the meatus of his penis. Thereupon he came to the surgery and I diagnosed traumatic rupture of the urethra. It was impossible (or, at any rate, I was unable) to pass a Jacques rubber catheter, but after some difficulty I succeeded in passing a silver catheter No. 8. This was tied in, and remained in situ for five days. The patient must have endured considerable discomfort meanwhile, for the sick-bay was situated in the extreme stern of the vessel on the upper deck, and the weather was such that on two occasions the patient's dinner was swept out of the hands of the hospital attendant while crossing the after-deck.

On arrival at Greenock I removed the catheter and put the patient ashore on a stretcher. He made a rapid recovery, and was discharged from hospital ten days after the accident.

Had the urethral rupture been complete no instrument could have been passed; and the case illustrates the advisability of exploring with a metal catheter before assuming completeness of the rupture.

Royal Mineral Water Hospital, Bath.—When this hospital is moved from its present site to the new one near the baths a large area of slum property will have to be cleared. It is thought that the new building should accommodate 300 patients. A sum of £50,000 will be needed for a laboratory, and the total expenditure will be about £250,000.

REVIEWS AND NOTICES OF BOOKS

The Rheumatic Diseases

Their Recognition and Treatment. By FRANCIS BACH, M.A., M.D. Oxon., Chief Assistant, St. Bartholomew's Hospital and the British Red Cross Society's Clinic for Rheumatism; Specialist in Rheumatic Diseases, St. Stephen's Hospital (L.C.C.). London: Cassell and Co., Ltd. 1935. Pp. 436. 12*s.* 6*d.*

CLOSE on the heels of the first report of the Royal College of Physicians' committee on chronic rheumatic diseases appears this volume, written by one of its members. It is a careful survey of everything that goes by the name of rheumatism, based on clinical experience and extensive study of the literature. Dr. Bach deplores the neglect of chronic rheumatism and its treatment by the teaching schools, which have rarely roused the student's real interest in the subject and have too often sent him into practice lamentably ill-equipped to deal with a prevalent and disabling condition. He observes that comparatively few specialists, of training and competence comparable with those of the first-class general physician, neurologist, or chest specialist, have in the past been engaged in this branch of medicine, and he contrasts the thoroughness with which the community, both lay and medical, organises the treatment of pulmonary tuberculosis with its apathy towards the rheumatic diseases which cause one-sixth of the industrial invalidity of the country. Such considerations seem to be his motive in preparing these descriptions of the main types of rheumatism, covering their clinical, pathological, radiological, and biochemical aspects, as well as describing their treatment. The book is too full to appeal to most general practitioners, but is to be warmly recommended to all the younger teachers of medicine, to the budding physicians, and especially to those who feel specially drawn to the problems of rheumatism.

The opening section deals with the general anatomy and physiology of skin muscles and joints, and with the investigation of the patient. So much space is given to recapitulating the details of an adequate general clinical examination, the importance of which is rightly emphasised, that "it is not possible to discuss the examination of the various joints and muscles"—which we find unfortunate. There follows a chapter on rheumatic fever, included for the sake of completeness and contrast; though there are hints of affinities between acute rheumatism and chronic arthritis, it is clinically expedient, in our present ignorance of their causes, to regard them as separate diseases. Then come descriptions of the various forms of chronic arthritis, grouped after the classification of the College committee under the two main headings of rheumatoid type and osteoarthritic type. This arrangement emphasises the similarity of some forms of gonococcal with "rheumatoid" arthritis, and the need for thorough search for a gonococcal focus, which the author holds is often missed. Of dental foci Dr. Bach is frankly sceptical; "the majority of so-called infective teeth, as judged by the radiologist," he writes, "are not the causative agent in rheumatic diseases." The varieties of spondylitis, and the associations between joint disease, disordered metabolism, and the ductless glands, are discussed separately, and there is an interesting, if somewhat speculative, section on muscular rheumatism and fibrositis. The last quarter of the book is a full and moderately critical account of treatment.

Illustrations are few, and some of them are familiar; many more specimens and some sections illustrating morbid anatomy would have been welcome. The style is clear and easy, though in places rather loose, and a few inaccuracies (such as the repeated measurement of phosphatase in milligrammes) have crept in. The great merit of the book is that, in addition to being interesting, comprehensive, and up to date, its outlook is balanced and detached. No theory of pathogenesis is urged beyond the limits to which the evidence will take it, and no treatment receives excessive commendation. It is a work of consolidation and will be valued by all who believe, with the author, that in the long run progress owes less to flashes of genius than to the accumulating results of many conscientious workers.

Essentials of Materia Medica, Pharmacology and Therapeutics

By R. H. MICKS, M.D. Dub., F.R.C.P.I., Professor of Pharmacology, Royal College of Surgeons in Ireland; Physician, Sir Patrick Dun's Hospital, Dublin. London: J. and A. Churchill Ltd. 1935. Pp. 395. 12*s.* 6*d.*

THE traditional method of writing text-books on materia medica and therapeutics is to describe the action of each drug as determined by the methods of experimental pharmacology, and then to discuss its possible therapeutic uses. The writers of such books at the beginning of this century had usually some training and experience in experimental work, but were primarily physicians, and their accounts were coloured by their clinical experience. Since that time, with the development of pharmacology as a science, text-books have been written in the main by exponents of the experimental method, who have naturally tended to emphasise this aspect of the subject. Prof. Micks writes as a clinical physician with, so he says, no personal experience of experimental pharmacology. He has measured the importance of a drug solely by its value in the treatment of disease, and has limited the scope of the book to such drugs as are administered internally and are of real value in therapeutics. The limitation is not so great as might have been anticipated by the sceptic. It is true that the author mentions only a limited number of pharmacopœial preparations, which he regards as the most active and the most important, but the reader will find an account of nearly all the drugs commonly dealt with in ordinary text-books, together with some of the more recently popular proprietary preparations. Nearly half the book is taken up with a discussion of drugs which have their main seat of action on the central and peripheral nervous system, while the others are grouped according to the particular system they are likely to affect therapeutically. In the consideration of individual drugs, the pharmacological action is, in the main, dealt with briefly and only in so far as it helps to explain the therapeutic uses.

Many readers will find the really interesting and valuable part of the book in the expression of the author's opinion on the value of a particular drug, and his advice as to how and in what conditions it should be used. He is refreshing, if perhaps at times a little dogmatic, in his statements about drugs of doubtful value. The whole is a pleasantly written account of clinical pharmacology by a physician of experience, who has reviewed his subject with judgment and balance.

Biochemical Laboratory Methods

For Students of the Biological Sciences. By CLARENCE AUSTIN MORROW, Ph.D., late Assistant Professor of Agricultural Biochemistry, University of Minnesota. Revised and rewritten by WILLIAM MARTIN SANDSTROM, Ph.D., Assistant Professor of Agricultural Biochemistry in the University. New York: John Wiley and Sons, Inc.; London: Chapman and Hall Limited. 1935. Pp. 319. 18*s.* 6*d.*

THIS is a text-book of biochemistry suitable for the student who is undertaking study in the biological sciences, such as agriculture, physiology, pathology, and so on. The first chapter gives a good series of experiments demonstrating the properties of colloids; the second is concerned with physical chemical investigations on plant saps. Other chapters deal with oxidation-reduction potential, the preparation of amino-acids, carbohydrates, enzymes, &c. The work has great value as a book of reference.

Care of the Aged, the Dying and the Dead

By ALFRED WORCESTER, M.D., Sc.D., Henry K. Oliver Professor of Hygiene, Harvard University. London: Baillière, Tindall and Cox. 1935. Pp. 77. 4*s.* 6*d.*

IN his preface the author has been at pains to justify the publication of this book; "some of the younger members of the profession," he writes, "although having enormously greater knowledge of the science of medicine, have less acquaintance than many of their elders with the art of medical practice. . . . Primarily, it depends upon devotion to the patient rather than to his disease." If this small book were put into the hands of all hospital residents and young practitioners, there might be less criticism of the overworked harassed expected-to-be-omniscient family doctor. It is a service to 'm to be reminded that successful treatment (at ny age) depends upon the coöperation of the patient as well as on scientific knowledge. The process of growing older will be accompanied in one patient by resentment and suspicion—resentment of nature's "encroachments," the first white hairs, various physical limitations. The man who, instead of happily enjoying his one round, bores his friends about his "fool of a doctor" who has knocked off his second round of golf; on the advice of valetudinarian friends, he seeks an "independent opinion" and falls an easy prey to the advertising charlatan. What a contrast to another patient who enters the stage of senescence so well described by Dr. George Draper as "the most interesting, useful, and happy. Enlarging powers of thought and opportunity for meditation offset waning capacities of bone and muscles. Creativeness in the realm of thought has often reached its highest expression at this period." Wholly rewarding are the patients of this class. Among other points emphasised by Dr. Worcester in the care of the aged are the value of occupational therapy; of "insisting upon continuance of . . . respectful treatment"; and remembering the loneliness of the old.

The section on the care of the dying is an equally humane consideration of the many ways in which a doctor can alleviate and help his moribund patients. "Whispering within their partial hearing is unpardonable." "It is his [the doctor's] function to decide when all treatment designed for restoration shall be replaced by what is more likely to comfort the patient." As to the relations, "much of the uncertainty as to what should be said or left unsaid on such occasions is owing to general ignorance of the fact that death is almost always preceded by perfect willingness to die." He quotes William Hunter's last words: "If I had strength enough to hold a pen, I would write how easy and pleasant a thing it is to die."

On the care of the dead Dr. Worcester is again firm and sound. He reminds us that often the suggestion of an autopsy is welcomed by relatives, who are probably relieved by knowing the facts as to the cause of death. He has no use for embalmers and the "mortuary artist" who complacently said: "Yes, we make a specialty of smiles." He deprecates the extortionate cost of elaborate funerals, and finally advocates cremation, which "depends upon hastening instead of retarding the natural return of the body to the dust."

Nutrition and Physical Fitness

Second edition. By L. JEAN BOGERT, Ph.D., Consultant in Nutrition, Delineator Institute, New York. London: W. B. Saunders Co., Ltd. 1935. Pp. 566. 13*s.*

THIS is a condensed treatise on the subject of nutrition based on writings and researches of many workers, whose findings the author has sifted and correlated. Considerable care and judgment have been exercised in the arrangement of the subject matter, which includes sections dealing with the metabolism of foodstuffs and the requirements of the body, the relationship of nutrition to intimate physiological processes, the planning of diets, the construction of menus, the feeding of children, pregnant and nursing mothers, and the special problems of diet which arise in disease. It should prove a useful book to students of dietetics.

Introduction to Comparative Zoology

By F. G. S. WHITFIELD, F.R.E.S., F.R.M.S., Entomologist to the Sudan Government; and A. H. WOOD, M.A., Entomologist to the Gezira Agricultural Research Service, Sudan Government. London: J. and A. Churchill Ltd. 1935. Pp. 354. 15*s.*

THIS is an admirable introduction to comparative anatomy suitable for medical and science students. The relationships between the types described are continually stressed in an interesting manner, and the diagrams are with a few exceptions good and mostly original. Since it is intended as a general introduction to zoology it is, however, to be regretted that the main section of the book deals exclusively with pure morphology; the physiological aspect is given little space and is isolated from the rest in a manner which is not likely to impress the student that form and function are in reality inseparable. No suggestion is made that students should perform elementary physiological experiments. But within the limits which the authors have set themselves the book is strongly to be recommended. Besides providing for the needs of the average student, it is written in such a manner as to encourage a deeper interest in the subject. Suggestions for further reading are also given.

THE LANCET

LONDON: SATURDAY, AUGUST 24, 1935

FIFTY-TWO YEARS LATER

On September 4th, Sir Thomas Barlow completes his ninetieth year, and to commemorate this event the *Archives of Disease in Childhood* for August are devoted to various aspects of infantile scurvy, the disease with which his name is most closely linked. British pædiatrics does itself and Sir Thomas great honour in the production of this "birthday number," for it enables physicians and investigators from England, America, Norway, and France to display something of the vast territory his work has opened up. And it is no disparagement of the contributions offered by his successors to say that Barlow's original paper, reproduced from the *Medico-Chirurgical Transactions* of 52 years ago, outshines them all. Of the 31 cases which form its basis 11 had been under his own care, and in reading the graphic clinical description it is easy to picture the child smitten with scurvy—and possible even perhaps to catch a faint North Country intonation in the writer. Previously Cheadle had recognised scurvy supervening on rickets and had realised that the disease was due to defective diet: "the essential factor, it has been proved over and over again, is," he wrote, "the absence of certain elements in the food."[1] But to Barlow we owe the demonstration that there is no such thing as "scurvy rickets"; that the disease is true scurvy occurring in infants; and that any rickets present is wholly independent, as Glisson had declared as long ago as 1650.

Barlow's clear conclusions made it easy to recognise and cure infantile scurvy, and as direct and indirect result of his work the disease has changed, and is changing, its character. In the first place it is now so rare that in the largest children's hospital in England only 9 cases have been seen in the last three years. Secondly, those children who develop it do so at an earlier age; for two decades, Dr. Still[2] says, it has been seldom encountered at ages above a year. This state of affairs he attributes to earlier diagnosis; but there are other factors also which have tended to lower both incidence and age of onset, and these relate to changes in feeding. In the days when Barlow wrote his papers the favourite diets for infants artificially fed were made up either from condensed milk or from proprietary foods; nowadays these have been largely supplanted by dried or pasteurised milk, in which vitamin C stands a better chance of survival. Even more important, however, is the conversion of the lay public to the belief that orange juice is necessary for a child's well-being—an advance in infant dietetics for which pædiatricians, infant welfare centres, and the Empire Marketing Board may all claim credit. For evidence that Great Britain has become "orange-minded" we need go no further than the fact that the consumption of this fruit last year was 29½ lb. per head of population. If asked why scurvy was not more common among the poor before the vogue of oranges we must refer, like Barlow, to the opinion of Cheadle. The children, said the latter, "soon begin to feed with their parents, and potatoes and gravy are almost invariably given them. This does not prevent them becoming rickety, but it seems to keep off scurvy; potatoes, as the late Dr. Baly proved, being an excellent antiscorbutic."[1] In 1878, it will be seen, there was already a great accumulation of practical knowledge of the disease; and the information provided by Prof. J. C. Drummond, on p. 459 of our present issue enables us to pay tribute to one of many—generally unknown—who made great sacrifices to gain such knowledge for us.

If frank infantile scurvy is nowadays a rarity, can we assume that, so far as antiscorbutic elements are concerned, the national infantile dietary is now perfect? Or has the clinical picture of scurvy been so far modified that it is not recognised? Work in progress is providing answers to these questions. The supposed existence of a latent scurvy has been derided by some clinicians, yet Barlow himself said that minor degrees are probably "not so rare as might be thought." Dr. E. A. Park and his associates, in a valuable communication[2] from Johns Hopkins Hospital, report that the time which frank scurvy took to develop in 37 infants was from two to nine months, which is longer than it takes in the adult—probably because traces of vitamin C usually remain in the pasteurised milk which most babies get. They were unable, however, either to detect any prodromal symptoms that would have made it possible to diagnose latent scurvy, or to discover the cause of the sudden outburst of acute symptoms. They compare this rapid onset to the sudden manifestation of acute tetany in a case of latent tetany, and the comparison is an apt one, since the existence of latent tetany is undoubted, and its sudden activation often seems to be attributable to infection, which is a factor that might equally determine the onset of acute scurvy. The presence of latent tetany can be shown by biochemical methods, and now that vitamin C has been isolated a biochemical test for latent scurvy has been elaborated by L. J. Harris and S. N. Ray.[3] As related by Mr. S. S. Zilva, D.Sc., whose fascinating story[2] should be read in full, it has been shown that the properties of vitamin C are possessed in full measure by *l*-ascorbic acid (known in the United States, perhaps unfortunately, as cevitamic acid). Applying the 2 : 6 dichloroindophenol test for this substance, HARRIS and RAY find that the normal child, being saturated with vitamin C, passes a fairly constant amount (0·03 mg. per c.cm.) in the urine. If a dose is given by mouth to a normal child, urinary excretion of the acid immediately increases; but in children suffering from scurvy the amount excreted is unusually low, and does not increase after the test dose, because the ascorbic acid is needed to make up the body's vitamin-C deficiency. From this it is deduced that if any child does not show a rise in excretion of ascorbic acid after a test dose it must be suffering from scurvy, latent or otherwise. Here then we have an excellent means of detecting "subclinical" vitamin-C deficiency—provided the indophenol test is an accurate one. Unluckily it is open to criticism on the ground of non-specificity; but the same accusation cannot, it is claimed, be maintained against the modification* now employed, at HIRST's suggestion, at the Children's Hospital, Birmingham, where it is accepted as clinically satisfactory. The figures obtained there are somewhat different from those of HARRIS and RAY, but do not invalidate their thesis or detract from the medical importance of their observations.

[2] Arch. Dis. Childhood, August, 1935.

[3] The Lancet, 1935, i., 71 and 462; see also pp. 100, 113, and 999.

The part played by ascorbic acid in metabolism has been much studied. It probably forms an oxidation-reduction system in the body and is concerned in tissue respiration. It is also one of the factors responsible for the maturation of the red cell, and Prof. L. G. PARSONS and Dr. W. C. SMALLWOOD[2] now offer evidence that it operates throughout the maturation of the red cell, from the reticulo-endothelial system to the erythrocyte, and not only, as usually stated, from normoblast to erythrocyte. Anæmia is not always to be found in scurvy, whether latent or acute, but it is nevertheless a specific symptom of the disease; it is usually normocytic and orthochromic but may be macrocytic. Suggestions have also been made that vitamin-C deficiency may be wholly or partly responsible for conditions other than scurvy, such as Addison's disease, acute rheumatism, pyorrhœa, and some forms of purpura. So far, however, there is no real evidence in favour of these possibilities, and in the case of rheumatism Prof. BRUCE PERRY presents evidence to the contrary in our present issue. The current opinion is that the vitamin is not stored in the body, and Dr. K. U. TOVERUD[2] finds that the amount contained in the liver of new-born Norwegian infants is small. But some animals are able to synthesise it themselves, and the idea is put forward by Prof. P. ROHMER and Dr. BEZSSONOFF[2] that the human infant likewise is able to do this during the first year of life; "the infant," they think, "does not become scorbutic because his food is lacking in vitamin C, but because the inherent function controlling the synthesis of this vitamin has become feeble or has disappeared." This view does not accord with clinical experience, and would require more proof before it could be accepted.

The question may be asked whether there are any clinical symptoms which, in association with HARRIS and RAY's test, can be held to make up a clinical picture of latent scurvy. It must be confessed that any such picture is very hazy. We owe the conception of latent scurvy largely to the late ALFRED HESS[4] who pointed out that suspicion should be awakened if in the absence of other causes a child fed on pasteurised milk lost its appetite, ceased to thrive and gain weight, showed increased knee-jerks, and perhaps had a rapid pulse and respiration. ROHMER and BEZSSONOFF describe prescorbutic dystrophy as characterised by pallor, anorexia, change in character, and a slowing of the increase in weight and also rarely of length; sometimes there is disturbance of digestion, sometimes an anæmia responding only to a combination of vitamin C and iron, and sometimes again a persistent pyrexia probably due to recurring infections. On the other hand, we have already commented on the inability of PARK and his colleagues, who looked out for all these features, to find any characteristic prodromal symptoms. The fact that the clinical picture is indefinite makes all the more valuable the means now at our disposal for estimating the urinary output of ascorbic acid and so establishing the existence of deficiency. The only other way of proving latent scurvy is to see whether it disappears when the patient is given vitamin C.

It has been the rare privilege of Sir THOMAS BARLOW that he has been able to witness, as a consequence of his work, the complete conquest of the acute manifestation of the disease which he described, and the abolition, not only of death from this cause but also of the intense suffering which preceded it. Moreover, he has seen a significant change in the character of the disease and the birth of a sure and certain hope that infantile scurvy even in its latent form will soon belong only to the past. Such a reward is vouchsafed to few men, and of Sir THOMAS BARLOW it may be said that none has deserved it more.

KYMOGRAPHY AND THE SURGERY OF PHTHISIS

FOR some years now kymography has been applied with interesting results to X ray examination of the chest. Its application in cardiology has recently been discussed in our columns.[5] A useful illustrated description of the method was recently given[6] by Dr. H. H. WEBER, working in the first medical clinic of the Berlin Charité. The method consists in taking an X ray photograph through the slits of a lead screen placed between the film and the patient. The slits are 12 mm. apart and 0·5 mm. across, and during the exposure the screen is moved a distance of 12 mm. at right-angles to the slits so that the picture which would at first consist of a series of lines gradually becomes a series of strips which widen until they meet at the moment the exposure ends. It differs from cinematography in which instantaneous pictures of the whole object are taken and placed in series, for it consists in a number of moving pictures —or, rather, moving objects on a stationary background—within a single outline. As Dr. WEBER puts it, kymography makes it possible to *read* movement, whereas cinematography makes it only possible to *see* movement. The cinematographic conception of movement is a judgment based on sensations of direction and of speed; kymographic reading is pure analysis and it is possible for anyone to interpret a kymogram at any time without further help. Incidentally this method of investigating the mechanism of respiration in the living patient has confirmed views expressed by Sir ARTHUR KEITH more than 20 years ago—namely, that the ventilation of the upper lobe is maintained by movement of the upper six ribs, while ventilation of the lower lobe is effected by movement of the diaphragm and lower ribs. These movements although synchronous are independent; with a free pleural space and normal interlobar sulcus diaphragmatic movement has no effect on the upper lobe.

---

* This modification is based on the fact that copper inactivates vitamin C and therefore two estimations are carried out on the same specimen of urine, one directly and the other after boiling with copper sulphate, the difference between the two figures giving the amount of ascorbic acid excreted.

[4] Scurvy, Past and Present, Philadelphia, 1920.

[5] THE LANCET, 1935, i., 221.

[6] Beitr. z. Klin. d. Tuberk., 1934, lxxxiv., 99.

There are certain practical applications of this knowledge, pointed out by Prof. E. SCHNEIDER, of Freiburg i. B., in an exhaustive paper.[7] It has, for instance, been found possible to exclude both upper lobes from active respiration by excision of the upper ribs on each side, and for respiration to be maintained by the two lower lobes ventilated by means of the diaphragm and the lower ribs. For long there has been dispute over the value of inducing paralysis of the diaphragm for an isolated lesion of the upper lobe; it is now clear that paralysis of the diaphragm can only affect the upper lobe if adhesions have formed in the interlobar sulcus. Kymography may make it possible to select with accuracy the cases suitable for phrenicectomy. For the induction of an artificial pneumothorax repeated punctures may be made in the attempt to find a free pleural space; the radiogram gives no help in selecting the best point for puncture. Kymography can give the required information and spare the patient needless discomfort; it may indeed make induction possible when the attempt would otherwise have been abandoned. All extensive operations on the chest wall are accompanied by the danger of mediastinal flutter, and before undertaking them it is important to know if the mediastinum is normally mobile; the radiogram may show gross deviation of the trachea, but kymography can give exact information. SCHNEIDER emphasises the modern view that collapse operations are designed to permit retraction of the diseased lung and so allow the natural healing tendency to attain its objective. A proper understanding of the mechanics of respiration enables this result to be attained without violating physiological principles and so the patient may be protected from post-operative complications. With a free pleural space an artificial pneumothorax should suffice to control the disease. When collapse of the diseased portion of lung is impeded by adhesions to the chest wall they should be divided through the endoscope. Attempts to stretch adhesions by increasing the gas pressure or prolonged trial of an incomplete pneumothorax no longer form part of the practice of an informed clinic. The first is responsible for infected effusions; the second may permit disease to progress to a stage at which any collapse operations would be futile.

Thoracoplasty is reserved for cases in which the pleural space is obliterated, and SCHNEIDER reviews the types of operation in use. The original Brauer-Friedrich method in which eleven ribs were removed in their entirety imposes so great a strain on the vascular and respiratory systems as to have led to its abandonment in the treatment of phthisis. Its successor, the Brauer subscapular thoracoplasty, in which the front portions of the ribs are left is also regarded by SCHNEIDER as unnecessarily severe. The operation of choice is the Sauerbruch paravertebral method in which ribs one to eleven are excised, each for a distance of 2–3 in. from the costotransverse articulation, danger of aspiration pneumonia being avoided by dividing the operation into two stages beginning with ribs six to eleven. This reduces the capacity of the operated side by 600 to 900 c.cm. some six to nine months after operation. In very ill patients the operation may be divided into three or more stages. Should a large cavity remain, as happens occasionally, a paraffin "plombe" may be inserted later. SCHNEIDER believes that there are cases of diffuse upper lobe disease in which the arrow resection of Wilms may be of service; in this a paravertebral resection of ribs one to eight is supplemented later by parasternal section of the costal cartilages. The new Italian operation of Monaldi in which phrenicectomy and excision of the first rib are combined with resection of antero-lateral segments of the second to seventh ribs appears to SCHNEIDER to be very limited in application. The Graf method of localised collapse of the upper lobe is attended with the danger of aspiration pneumonia. SCHNEIDER accordingly does the operation in two stages, in the first of which the three upper ribs are exposed from in front and the anterior portions excised from the costo-chondral junction to the mid-axillary line. And he does not follow Graf in stripping the diseased lung from the parietes. Phrenicectomy he regards as useful in exudative disease limited to one lung, in lesions of the lower or middle lobes, and as an accessory to Graf thoracoplasty when there is fibrosis in the interlobar sulcus. He is as modest in his claims for phrenicectomy as an adjuvant to other operations as is Mr. MORRISTON DAVIES in his article on p. 418 of this issue. There are certain cases, Mr. DAVIES thinks, in which it is advisable to paralyse the dome of the diaphragm some time before operation, in order to improve the patient's general health. But he would then only crush the phrenic nerve and allow it to recover again.

---

[7] Med. Klin., June 7th, 1935, p. 737.

SCHNEIDER concludes his survey by expressing regret that the selective nature of modern operation for phthisis is still not generally appreciated and that many patients who might be healed by surgical intervention are restrained by the mistaken belief that thoracoplasty is always a severe and deforming operation. This was true of the original method, but is no longer true, while kymography is likely to help still further in the selection of an operation appropriate for the individual.

TRACHOMA

THE last five years' research on trachoma is described by Dr. M. D. MACKENZIE in a report issued by the Health Section of the League of Nations.[1] The information has been accumulated from various countries in Europe, Asia, Africa, and America, and Dr. MACKENZIE points out that the first difficulty that confronts the statistician is that the disease is insufficiently defined. A specially trained ophthalmologist is needed for its diagnosis in doubtful cases, and we cannot fairly judge of its incidence in a whole country on a basis of figures from selected areas. Moreover, cases of undoubted trachoma without any secondary infection, although necessarily very chronic, may run a comparatively mild course, reaching a stage of permanent slight scarring without any loss of vision. Even in Egypt, one of the most heavily infected countries in the world, A. F. MACCALLAN has demonstrated the importance of the large number of cases in which natural cure has occurred, and in China, according to A. PILLAT, the disease appears to be of a modified type, a large proportion of the patients being cured spontaneously. As to ætiology, it is universally admitted that the disease is only rampant among a poor and ignorant population, but it has been proved to be contagious in the acute stage. (Compare the story of the child at Swanley who was about to be discharged after a mild attack of blepharitis, but, not wishing to go home to a slum life in East London, deliberately infected her eyes with discharge from those of a child under treatment for acute trachoma—thus securing another year before she could be sent away.[2]) In heavily infected countries, apparently, infection almost always takes place in infancy in the home before school age and not at school. Thus in certain schools in South Tunisia, including 5000 trachomatous children, several hundred healthy French children were found who had remained uninfected during their school life in classes composed of 60–80 per cent. of trachomatous coevals. This seems surprising but other reports are consistent with it.

About the causative agent very little is really known, despite much pathological investigation. Possibly the Prowazek-Halberstaedter inclusion bodies bear some causal relation to the disease, but their presence is by no means constant. Similarly, the *Bacillus granulosis* of Noguchi is not now considered to be responsible, and NOGUCHI's positive results from the inoculation of monkeys are no longer held to be convincing, since monkeys are found to get a spontaneous follicular conjunctivitis which is liable to be confused with trachoma. Human inoculation experiments with *B. granulosis* appear, moreover, to have been negative. Thus so far as a bacteriological cause of trachoma is concerned, we are still uncertain whether this is a visible bacterium or a filtrable virus. But there seems to be more and more evidence in favour of the latter view.

Little new can be said about treatment, for the work of the last five years makes it clear that no really satisfactory remedies are yet available. For routine purpose copper sulphate and silver nitrate remain the favourites, but as alternatives or adjuvants various workers in different countries advocate chaulmoogra oil, mercuric chloride 1 in 1000 applied to each follicle after expression of its contents, and carbon dioxide snow, and during the last few years the value of diathermy has been especially urged in France. This last seems to be an excellent means of treating mild cases, and good in moderately severe ones, but it is quite insufficient when the disease is well advanced. The most important problem, however, is, afte all, that of prophylaxis. As already noted, it agreed that trachoma is, for all practical purpo limited throughout the world to poor and igno populations, with their accompanying evil overcrowding and dirt. Legislation for the pulsory notification of the disease has pr itself, in France, to be of little or no value. the heavily infected countries where inf almost always occurs during early infancy an at school, the four lines on which preve and treatment can be most usefully carrie are: (1) the provision of adequate staff pro trained for trachoma work; (2) work amo mothers and infants; (3) work in the schoo and (4) general propaganda. According to MA CALLAN two years' special ophthalmic work und the supervision of a highly qualified surgeon necessary before a graduate can take charge of trachoma clinic. On the other hand, a month training is sufficient to enable practitioners t treat cases of trachoma with drugs, apart fro operative procedures. The instruction of futu mothers, when girls at school, appears to be t only hopeful possibility of limiting the infectio of infants. If the mother has an infective stag of trachoma herself and takes no special precautions she is destined inevitably to infect her newly born child with trachoma during the first year or two of life. As to work in the schools, a distinction must be drawn between those countries where trachoma is general and those where it is only exceptional. In the former a policy of segregation is quite impracticable, but the teaching of ocular hygiene and simple treatment with drops and the like may be carried out. In the latter segregation may be highly successful. For instance, in the middle of the nineteenth century trachoma was rife in certain of the poor-law schools of London, but it has since become a rarity in this country.

ANNOTATIONS

IMPROVING THE MINER'S LOT

ONLY a few years ago if one talked to a miner's wife about pit-head baths her comment as likely as not would be: "What do we want them for? Let my man come home and I'll get the muck off him." To-day it is said that where the new housing estates are attached to pits the women-folk will not allow the men to "mess up my clean bathroom"; they are bidden leave their dirt where they got it. Among the causes of this change in opinion and outlook is the work of the Miners' Welfare Fund, and this work ought to be much better known. Conditions in many mining villages are a heavy burden on the national conscience, and the Fund is doing what it can to secure the health and happiness of a large section of the population, whose lives are all too often spent in circumstances of danger and depression. Originally instituted in 1920 from a levy of 1*d.* a ton on every ton of coal produced, the Fund was augmented in 1926 by a levy of 5 per cent. on mining royalties. The latest report of the responsible committee[1] shows that the output levy was reduced last year to ½*d.* a ton, but the estimated receipts now amount to £600,000 per annum, and the total obtained since 1920 is over £14,000,000. The diverse activities of the Fund are indicated by the headings Recreation, Pithead Baths, Health, Education, Research. Direct health expenditure is shown as follows:—

	Total to end of 1934.		1934 only
	£		£
Convalescent homes and funds	2,593,686	....	73,106
Hospitals	379,564	....	5,598
Ambulance services ..	120,927	....	4,257
Special medical treatment and appliances	86,519	....	707
Nursing services	65,558	....	5,150

The largest item is in respect of convalescent homes, and these have been established at, amongst other places, Blackpool, Ulverston, Skegness, Scalby, Cromer, Troon. It needs no imagination to realise the boon after illness of such transition from a pit village, especially as the amenities are sometimes extended to women and children as well as men. Hospitals which serve mining communities have materially benefited by grants towards extensions or special equipment, such as X ray plant, while grants have also been made to ambulance and nursing services. Up to the end of last year the total thus allocated was over 3¼ million pounds.

Of services operating indirectly on health, the provision of pithead baths takes precedence. There are now 186 installations of these, catering for 28 per cent. of the men employed in the industry, and the number is steadily rising. There are facilities not only for bathing but also for drying pit garments, while first-aid rooms and often a canteen are also available. This is a revolution in the life of the miner and his household. To leave behind the grime of the pit, to leave behind in a drying chamber sodden working attire, to travel home and arrive home unstamped of all the marks of the nether regions, must involve a heightening of self-respect and must have a beneficent effect on health. That the facilities are appreciated is shown by the fact that the percentage of users where provision has been made is 87, though a weekly contribution is required, usually of 3*d.* to 6*d.* Not less important is the saving of drudgery and expense to the miner's wife. It has been well said that she may have a 24-hour day with men working two, or perhaps three, shifts and children returning from school. The help given her by pithead baths can only be realised by those who have seen a burly, begrimed miner sitting in a small bath in the only living room of a small cottage, or have seen on the clothes-line recently removed pit garments frozen stiff.

Of similar value are the grants made for recreation, involving up to the end of 1934 a total of nearly 5 million pounds. From this source are provided institutes and halls, recreation grounds, and boys' clubs and camps; children are especially catered for. All these provisions are of inestimable value in amelioration of what has been too long regarded as the inevitably drab environment of the industry. Education has been assisted to the extent of over a million pounds, mainly by the provision and equipment of buildings for mining instruction, and by scholarship assistance to the children of miners. A further valuable item is the making of grants to the Safety in Mines Research Board. To turn back from this report to pages which reveal earlier conditions in the industry—e.g., the report of the Children's Employment Commission in 1842—is to gain a heartening sense of the progress which has been made towards social feeling and understanding. It affords some relief from contemplation of the unhappy conditions which still cast a blight over the coalfields.

PLANTAR WARTS

A SMALL epidemic of plantar warts is mentioned by Dr. G. Chaikin, a divisional medical officer of the L.C.C., in the Council's Report for 1934 (vol. iii., part 2). There were 16 cases, all in girls, and the diagnosis was confirmed in each case by Dr. G. W. Bamber. Although more common in girls, this infection does not spare boys and has occasionally wrecked the chances of junior laurels in the football and cricket fields. In adults the condition is rare, although occasional cases are seen in women above the age of puberty. The relative delicacy of the epidermis in women and children may account for their greater proclivity to the disease. Some patients give a history of injury, as by a thorn or splinter, but the majority are not conscious of any such cause and it would seem that the virus—now generally accepted as filter-passing—can enter the epidermis without breach of the surface. Once established the plantar wart, unlike its fellows on the upper extremity, does not heal of itself. How long it may persist is unknown, for the associated pain and disability demand relief, and treatment by suggestion, occasionally successful in other localisations, appears to fail in this. Epidemics of the infection prove its contagious character, but they are rare, and might not be difficult to prevent. A weekly inspection by a nurse (or even the bath attendant) of the soles of all the children who use a public swimming bath or pool regularly would certainly be a more effective prophylactic than the application of antiseptics to bath-mats and wooden grids. It is next to impossible to prohibit a child in a swimming suit from running about barefoot and what is to prevent others from treading in his footsteps? The segregation of an infected child from a bath until cured would be unpopular but salutary. By far the most handy instrument of treatment is the X ray tube, but it has grave risks unless used with the greatest care. The L.C.C. report states that in every case a dose of a pastille and a half was given, and a second dose after the lapse of a month if the first was not sufficient; but no word is said about the risk of giving three times the normal skin-tolerance dose within 28 days. Many dermatologists will have seen X ray ulcers develop months or years after an application. For a banal affection like a wart, in which there are so many other curative means to hand, it would seem unnecessary to take any such risk.

NINTH INTERNATIONAL DERMATOLOGICAL CONGRESS: BUDAPEST

THIS Congress will be held in Budapest between Sept. 13th and 21st, 1935, as announced in these columns earlier in the year. The president of the congress is Louis Nékám, professor of dermatology in Budapest University. Nékám is a remarkable man, as will be gathered from the following note from a medical correspondent and friend. "Nékám," he says, "as well as physician and specialist, is a linguist, classical scholar, and artist. He takes a special pride in his descent from an Englishman, Alexander Neckam (1157–1217), and has always had an especial affection for the English. I met him for the first time during the International Dermatological Congress in Paris in 1900, and have enjoyed his friendship ever since. He has visited England in the interval and I have been his guest in Budapest and seen him in his wonderful clinic. This was in 1913 and at that time he was going to send his two sons to English public schools, but the war frustrated this intention. Nékám was sentenced to death immediately after the war, during the Bela Kun despotism, but the Rumanians relieved Budapest from Bela Kun before the edict could be carried out, and Nékám was able to continue his career and filled the high office of Rector of his university two or three years ago. A delightful feature of the approaching congress has been the communications from Nékám in classical Latin, and the announcement of the themes for discussions in the same language."

Many governments and important universities are ending official representatives to the congress, which will have the complete political patronage of Hungary. The Hungarian railways are giving a rebate of 50 per cent. to the members, while the Hungarian Foreign Office will grant them free visas. German, Belgian, Dutch, Austrian, Swiss, Italian, Czechoslovakian, and French railways are also granting substantial rebates on their fares. The programme is comprehensive. There are six principal "commissions" or sections, each presided over by a representative of a different foreign country. Hungary chivalrously evaded the nomination of any of their own countrymen. At the first commission, presided over by the great dermatologist Dr. Jean Darier, of Paris, the establishment of an international permanent Dermatological Association will be debated; the second commission deals with the Reform of Dermatological Terminology (president, Prof. Rille of Leipzig); the third with the Modern Classification of Diseases of the Skin (president, Prof. Howard Fox of New York); the fourth with the Teaching of Dermatology (president, Prof. Gougerot of Paris); the fifth with the Organisation of a Central Exchange for Dermatological and Venereal Exhibits and Data (president, Prof. Tommasi of Palermo); and the sixth with the Practice of Dermatology and Venereal Disease (president, Sir Ernest Graham-Little). Three conferences have been arranged dealing with dermatological disease in connexion with tuberculosis, with syphilis, and with occupational diseases. Prof. Marek, of Budapest, will preside over a discussion upon comparative dermatology, while further subjects to be dealt with in session concern physiology of the skin and the relations to internal organs, allergy in dermatology and syphilis, and dermatological disease due to filtrable viruses. A large number of individual communications are also announced.

The programme of social entertainment includes a reception by the Regent, Nicholas Horthy de Nagybanya. The British secretary is Dr. A. M. H. Gray, 69, Harley-street, London, to whom inquiries should be addressed. The accepted languages of the congress are English, French, German, and Italian, and the subscription for full membership, open to any medical practitioner, is £2 8*s*. English money.

RELIEF OF ANIMAL SUFFERING

THE last issue of the quarterly journal of the Research Defence Society contains a valuable little article with this title communicated by Sir Frederick Hobday. The essay is made up of the ninth Stephen Paget memorial lecture which was delivered at the last annual general meeting of the Research Defence Society, and it is interesting to learn from its preface that the work and interest taken by the Research Defence Society in certain testamentary dispositions ensured a sum of £25,000 accruing to the Royal Veterinary College. Of the many interesting subjects touched on by Sir Frederick, probably his description of the electric killer attracted the most attention. With this instrument, after it has been plugged in at some source of electrical supply, the animal is just touched on the side of the head and death ensues. All the smaller food animals in England are killed by it now we learn, and, although as yet in the case of sheep the process is permissive and not compulsory, some 690 county councils have agreed to alter in the regulations the word "may" into the word "shall," so that there will soon be no place where sheep are not killed save through the humane killer. The electrical killer can also be employed as an anæsthetic for operation, the animal receiving a current for a few seconds, which renders it apparently unconscious for about 2½ minutes. It should be mentioned, however, that there are still some who do not feel certain of the efficacy of this process, and we may recall that in our correspondence columns last December Capt. C. W. Hume expressed grave doubt about the reality of the anæsthesia and, by consequence, the humanity of the slaughter. At various points in the lecture Sir Frederick gave examples of voracity, a subject which always excites wonder and amusement, whether the odd articles swallowed illustrate the perverted taste of the human subject or of any other animal. Cows have swallowed silk stockings, and one appears to have committed suicide in the attempt to swallow a sheet. Within the stomach and intestines of horses there have been found stones, nails, piping, and wire to an incredible extent, and dogs appear equally careless of consequence when indulging in odd diets. The adventurous surgery of the modern veterinary expert has obviously many opportunities, and its description formed the more exciting features of Sir Frederick's address, but he prefaced his words with remarks of the greatest political significance, and it is to be hoped that they also received attention. Agriculture he described as the backbone of civilisation, and the wealth of a country depends upon its animals. He said that in this country there are 930,000 horses, six and a half million cattle, seventeen and a half million sheep, two million pigs, and three million dogs—he gave no census of cats or poultry. With the better day that is promised for British agriculture it is well to know that the aggregate value at the present moment of farm animals in Great Britain is over one hundred and fifty millions, and that we produce some sixty million pounds worth of milk annually. The prevention of disease among our stock is therefore a matter of the greatest financial importance and a more generous endowment of the veterinary profession is definitely indicated. Preventive medicine among animals is in a favourable position in a country which is surrounded by water; eradication of disease becomes a possibility, so that a return is certain for any efforts spent.

A PUZZLE IN THE ÆTIOLOGY OF CANCER

A STRIKING example of the familial incidence of cancer is reported from Georgia by C. W. and C. P. Roberts.[1] The family comprised five girls and two boys, and within a few months of one another one of the boys, aged 23, and two of the sisters, aged respectively 17 and 13, developed bone sarcomata. The months when they came under observation were August, 1933, January, 1934, and February, 1934, respectively. The disease took a rapid course and they died in May, 1934, July, 1934, and January, 1935. In each case the seat of the disease was a long bone of the same side—the right one—namely, the tibia, femur, and humerus. Histologically the growth was in two cases a round-celled osteogenic sarcoma, in the third case a fibrosarcoma. There is no history of cancer in the family and the other sisters, aged 21, 19, and 10, and the youngest brother, aged 6, are alive and well. This group of cases would furnish a good subject for a discussion among adherents of the two opposed theories concerning the origin of cancer. Those who hold the view that genetic factors are of paramount importance will accept them as supporting their view. Adherents of the virus theory will point out that the simultaneous occurrence in three people of varying age, living in close contact with one another, suggests an extraneous agent rather than genetic factors. The authors of the report take an intermediate position postulating some extraneous factors, not necessarily of an infective nature, acting on persons whose osseous system was genetically susceptible to the development of malignancy.

TSETSE-FLY CONTROL

THE report of the East Africa Sub-committee of the Tsetse-fly Committee (Cmd. 4951, H.M. Stationery Office; 1s.) brings to a focus the many facets which go to make up the sleeping sickness problem, and shows very clearly how essential it is that this problem should be attacked from all angles if successful control is ever to be achieved. The three main methods of approach are by (1) administrative measures: the movement of populations, the evacuation of certain selected areas and the closer settlement of others, measures which demand a thorough and sympathetic understanding of local conditions; (2) the eradication of the tsetse-fly; and (3) the use of drugs. It is a curious and unforeseen result of the *pax Britannica* that as the native African, in Northern Nigeria, in Nyasaland and elsewhere, has acquired a feeling of security, he should have begun to indulge to the full his propensity for establishing little family settlements in the bush—and so to have led during recent years to a great increase in sleeping sickness. Considerable success is being achieved in parts of West and East Africa in weaning him away from this habit and bringing him again into larger settlements. In the matter of tsetse-fly control, it has come to be realised that this can only be effective if it is based upon a thorough understanding of the natural history of the fly. But colonial governments are apt to want the results without the fundamental study, and it is a triumph for the Tsetse Research Department of the Tanganyika Territory that they should have persisted in making a scientific study of the habits of the fly at the same time as they devised their methods of control. The results have been promising, and the department is congratulated by the subcommittee. The same realisation of the necessity for fundamental research is shown by the subcommittee in the recommendations for the continued study of the behaviour and relationships of trypanosomes, the action of trypanocidal drugs, and the pathology of sleeping sickness.

ARTIFICIAL RESPIRATION: THE HOLGER NIELSEN METHOD

IN a recent leading article (July 20th) the claims were discussed of various manual methods of artificial respiration. Col. Holger Nielsen who is sports inspector at Gjentofte, a seaside suburb of Copenhagen, has evolved[1] a method which has now been adopted by the Danish Red Cross Society and the Danish Life Saving Association. He has found that whereas Schäfer's method can start automatic respiration more rapidly than Silvester's, the latter method causes a greater depth of respiration. His own method combines the features of both Silvester's and Schäfer's.

> The patient is placed in the prone position with the hands folded, and forming a cushion underneath the forehead. A handkerchief is put on the ground underneath the face in order to prevent inhalation of dust. As a preliminary measure the operator slaps the patient's back two or three times to make the mouth open and the tongue fall forward. He then kneels on one knee in front of and facing the patient's head, placing his hands on the scapulæ. He now exerts pressure for 2½ seconds on the chest by swaying gently forward on his outstretched arms. Then he relaxes and sways backwards, at the same time allowing his hands to slip back over the patient's shoulders and to grasp the arms midway between the axilla and the elbow. The patient is then partially lifted by the arms for 2½ seconds. The double movement is done in about 7 seconds or 8 or 9 times in a minute. If signs of returning life are seen the "lifting" movement is discontinued, and only the rhythmical pressure on the chest is carried out until automatic respiration is firmly established. It is thought that there might be over-ventilation of the lungs when the lifting movement is carried past this point, leading to a diminished concentration of CO_2 in the blood.

It seems that Prof. A. Krogh has tested the method exhaustively and has been able to give it unqualified endorsement.[2] He finds that the simple shoulder pressure alone, without the "lift" of the arms, is 10 per cent. more efficient than the rib pressure of Schäfer's method. On the other hand C. Sillevaerts says[3] that the Holger Nielsen method is more difficult to perform than those of Howard and Schäfer, but it has the advantage that the viscera and the ribs are unlikely to be injured because the pressure is applied to a strong area of the thoracic wall. Before the method is adopted widely it will doubtless require further experimental and practical tests. But these tests should be made.

INGLEBY

As a preface to the Ingleby lectures for 1935, which appear at the front of our issue, Dr. K. D. Wilkinson gave some account of the man in whose memory the lectureship was founded. John Tomlinson Ingleby was born in Cheadle in Staffordshire on March 7th, 1794. He served five years' apprenticeship to a Mr. Bourne, a surgeon in Cheadle, and then, after working in London and Edinburgh, he obtained the diploma of member of the College of Surgeons of England in 1816, and immediately came to Birmingham where he was appointed surgeon to the dispensary, a post he retained until 1840. He soon established a reputation in the town as a sound practitioner, so that when in 1828 Mr. Sands Cox sought teachers for the recently established medical school, Mr. Ingleby was appointed lecturer in midwifery. At first he lectured at No. 24, Temple-row, but the school was soon moved to more commodious quarters in Snow Hill (a site obliterated later by the construction of the Great Western railway station), and in 1834 a second move occurred to a building bought by Mr. Cox in Paradise-street, the number of students having risen to ninety. Up to this year each lecturer although himself unpaid had to pay a proportion of the expenses—rent, rates, &c.—of the school. By 1838 the course in midwifery had been much extended, some sixty lectures being given in the spring term on five mornings a week at 7.45 A.M., and in 1839 Dr. Berry became associate lecturer. From the date of his appointment as lecturer in midwifery Ingleby devoted himself to the special study of obstetrics, and established himself as the first obstetric specialist in Birmingham. His European reputation followed publication of a book on Uterine Hæmorrhage in 1832, and a second on Facts and Cases in Obstetric Medicine in 1837. These works gained him election as M.D. Heidelberg and fellow of the Royal College of Surgeons of Edinburgh—the first in Birmingham. Both books are written in clear concise English, which was as unusual at that date as it is now. Ingleby recommended the use of ergot of rye to assist uterine contraction, and transfusion of blood as a useful and life-saving measure when blood loss has been severe. A transfusion syringe, he wrote, should be in the possession of every person practising midwifery. Dr. Wilkinson describes Mr. Ingleby as a spare man, of medium height, with dark grey hair, and a rather peculiar awkward swinging gait. He was restless, excitable, nervous, and perhaps a bit hypochondriacal. His appetite and sleep were always spoiled by a worrying case, but it is recorded that he was never known to be angry, and that "he was a remarkable exception to the mass of our profession in the fact that he was never heard to speak with discourtesy or disparagement of a fellow practitioner."

THE FIRST CHANNEL-SWIMMER

SIXTY years ago, on August 25th, 1875, Captain Webb swam from Dover to Calais in 21 hours 45 minutes. On July 3rd he had swum from Blackwall Pier to Gravesend, a distance of 20 miles, in 4 hours and 45 minutes. In commenting on these feats THE LANCET pointed out there were still a few people alive who could remember when Byron swam the Hellespont and suggested that such natatory enterprises might well become common. It was not until 1911 however that the Channel was swum again (by T. W. Burgess), and it is notable that not until 1923 was Captain Webb's time appreciably decreased; indeed for the England to France crossing he held the record till last year, though Georges Michel swam from Gris-nez to Dover in 1926 in only 11 hours and 5 minutes.

It is difficult for us to imagine the excitement Webb's effort aroused; since the spate of the 1920's we have come to recognise Channel-swimmers as an esoteric but definite sect of the community. THE LANCET had particular reasons for interest, since the hero had a medical father and brother, and the latter, Dr. Thomas Law Webb, communicated to our columns a short account of Captain Webb's sensations immediately after his swim. On going to bed when he arrived in France he had taken his own temperature and found it to be 98° F. On waking five hours later he felt hot and feverish and found that it was 101°. He felt his pulse and thought it was "slower than usual." After a few hours' more sleep he woke up feeling quite well save for a little stiffness. Apparently he did not use goggles and had been almost blinded by the salt water. He was later examined by Mr. Henry Smith, surgeon to King's College Hospital, who refers to the *extraordinary volume of air entering his lungs at each inspiration.*[1] Webb was at this time 27 years of age; he was 5 feet 8 inches in height and weighed 14½ stone. Later he aroused some medical interest once more when a sphygmographic tracing of his pulse was published[2] as being the standard for a normal heart and arteries—a conclusion challenged in the following week by a correspondent, who described it as typical of a heart which had undergone *inordinate strain* and would in time recover.

A leading article on Sept. 26th declared that the best training for extreme exertion is sound general health, and suggested that a good deal of Webb's success was due to his not feeling the cold. His success is put down to the fact that he was a straightforward swimmer, and waste of energy in "fancy swimming" is deplored as wanton. "Plain, straight-ahead swimming with the breast-stroke," said the writer firmly, "is the one worthy enterprise."

PROGESTERONE

INTERNATIONAL standards for the sex hormones were discussed at a meeting of a section of the Permanent Health Commission of the League of Nations held in London last July with Sir Henry Dale, F.R.S., as chairman. Problems of nomenclature were raised among others, and in our correspondence columns this week will be found an announcement on the name of the corpus luteum hormone drawn up by four workers who have added much to our knowledge of this substance—Allen of Rochester, N.Y., Butenandt of Danzig, Corner of Rochester, and Slotta of Breslau.

Lord Linlithgow, who is to take up his duties as Viceroy of India next April, has been chairman of the Medical Research Council since September, 1934, when he succeeded Lord D'Abernon.

INDEX TO "THE LANCET," VOL. I., 1935

THE Index and Title-page of Vol. I., 1935, which was completed with the issue of June 29th, is now ready. A copy will be sent *gratis* to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXVI.—PROGNOSIS IN FRACTURES OF THE BODIES OF THE VERTEBRÆ

ALMOST all fractures of the bodies of the vertebræ are of the crush variety. These fractures are always produced by forcible flexion of the spine and are generally found where the spine is most mobile, from the 11th thoracic to the 2nd lumbar vertebræ or from the 3rd to the 6th cervical vertebræ. In most cases the injured vertebra becomes wedge-shaped, the sharp end of the wedge being anterior. This deformity is brought about in the following way: a horizontal fracture occurs, starting at the anterior border of the vertebra near its centre and extending backwards, roughly parallel to the upper surface of the bone. The upper portion is then impacted into the lower fragment. The maximum amount of impaction occurs anteriorly. The X ray appearance in a recent fracture is characteristic, and where the impaction occurs increased density of the shadow is shown. This was described by the late Dr. Stanley Melville as "sugar-loafing." Although the major deformity produced in the vertebra is one of antero-posterior wedging a certain amount of lateral wedging may also be found. In a small number of cases of crush fracture neither anterior nor lateral wedging is apparent, but instead, a depression occurs in the centre of the vertebra. This has recently been named by William Rogers of Boston "sauceriza-tion," a word which he has coined to indicate the shallow, saucer-like depression appearing in the upper surface of the bone. Occasionally a portion of the bone is separated from the body anteriorly. This injury is generally associated with a subluxation between the body of the injured vertebra and the one above. In many cases where a severe crush fracture of the body of a vertebra occurs a lesser degree of crushing is found in the neighbouring vertebræ. In all cases of fractured vertebra one or other of the intervertebral discs adjacent to the vertebra is injured. Since in these cases the fractures are produced by indirect violence it is exceptional to find any material injury to the soft parts in the neighbourhood of the fracture.

Success in treatment depends first, upon an early diagnosis, and secondly, of course, upon the type of treatment adopted. Out of a very large number of cases injured in industrial accidents and examined by me on behalf of insurance companies, in no single instance was there a record of any attempt having been made to reduce the impacted fracture. In this series of cases only 11 per cent. ultimately returned to their pre-accident work; and the average period of incapacity exceeded two years. In most of these cases the fractured vertebra had not been diagnosed and the treatment adopted was vaguely described as "rest and liniment."

Results following Disimpaction and Immobilisation

In an uncomplicated case of fracture of the body of the vertebra, treatment by disimpaction of the fracture and proper immobilisation of the spine offers an excellent chance of cure. Until recently surgeons have been afraid to attempt to reduce such fractures lest they caused irreparable injury to the spinal cord. The possibility of injury to the cord, however, if proper procedure is adopted, is remote. If a very careful stereoscopic examination of films of the spine shows that both pedicles and the articular processes of the vertebra are intact only very exceptional violence will cause a subluxation of a vertebra and consequent injury to the cord.

In such cases a rapid method of reduction of the fracture may be undertaken. There are various methods of achieving reduction, but all depend upon forcible hyper-extension of the spine relying upon the intervertebral discs and the anterior common ligament to pull out the impacted portion of the bone. When it is quite certain that there is no bone injury apart from that to the centrum, reduction may be effected under an anæsthetic. In other cases reduction should be effected without an anæsthetic, and performed gradually, careful watch being kept upon the patient both for local pain and for interference with the leg reflexes. This gradual reduction without anæsthetic may be extended over a period of about seven days, but better results are generally obtained if the whole operation is carried through in less than an hour. After reduction of the fracture the spine is immobilised while still in the hyper-extended position. The immobilisation may be effected in four different ways; (1) with the patient lying in a plaster shell, in which case an anterior shell is also made and for some part of the day the patient may be turned over, lying in the anterior shell while the back receives attention. (2) a complete plaster jacket may be applied and the patient treated in the recumbent position. (3) again a plaster jacket may be used and the patient allowed to walk. (4) a bone-grafting operation may be undertaken to secure fusion of the injured vertebra with those above and below.

However obtained, fixation of the spine must be rigidly maintained until repeated X ray examinations show complete re-organisation of the injured vertebra. The time taken to secure consolidation of the bone varies in different cases, the average being between two and eight months, although in some cases it is as long as three years. After reduction of the fracture there is no tendency to recurrence of the displacement in cases treated in the recumbent position, but in those treated by the ambulatory method in a plaster jacket a small proportion (estimated by Rogers as 13 per cent.) show recurrence of the deformity in the bone.

The fate of the intervertebral disc, however, is not as happy as that of the bone. In almost all cases it gradually gets flattened out so that the space between the injured vertebra and its neighbour becomes progressively lessened and in this way, although after the initial reduction of the fracture the contour of the spinal column is restored, when the patient gets about a very slight return of deformity consequent upon this diminution in the intervertebral space becomes apparent. With the diminution of the intervertebral space proliferation of the bone of the contiguous margins of the vertebræ usually occurs and not infrequently fusion between the vertebræ is thus obtained. This bony proliferation is frequently demonstrated in X ray films as evidence of osteoarthritis of the spine and proof of local pain. This is, of course, a mistake. It is just buttressing of the bone produced in an effort to restore mechanical stability.

The choice of treatment, whether by the recumbent or the ambulatory method, depends partly upon the site of fracture and partly upon the individual patient. Only fractures occurring where the spine is convex forwards, e.g., about the 2nd, 3rd or 4th lumbar vertebræ, should be treated by the ambulatory method. This method is definitely contra-indicated where the spine is concave forwards as in the mid-thoracic region. It is also contra-indicated in very fat patients because they are apt to lose weight in the early weeks of treatment. The plaster jacket then becomes loose and no longer gives adequate support. Ambulatory treatment, however, has the great advantage of improving the morale of the patient and in keeping up his general health and muscular tone. When firm consolidation of the bone has been obtained and the plaster jacket is removed the patient is still suffering from two conditions—extreme lordosis in the lumbar region and extreme weakness of the erector spinæ muscle. Both these conditions must be remedied before the patient is cured. It is generally necessary to fit the patient with some form of spinal brace to relieve the strain upon the erector spinæ muscle. This brace has to be worn for from one to three months whilst active treatment is adopted to improve the tone of the muscle and gradually to restore the spine to its normal contour. During this period the muscle is particularly susceptible to strain and if deformity still exists in the spine this susceptibility persists indefinitely because of the mechanical disadvantage at which different segments of the muscle act.

The period of fixation of the spine may be taken as a rough guide to the period that will be necessary to restore the tone of the back muscles and an equal period must be allowed for them to adapt themselves to the altered mechanical stresses.

Complications

Injury to the spinal cord.—This may result from direct pressure by a broken or dislocated vertebra or by a collection of blood or inflammatory exudate. Mostly the symptoms come on at the time of the accident, but where the pressure is due to inflammatory processes, or in those rare cases where it is associated with late collapse of the body of the vertebra, symptoms may start weeks or even months after the initial injury. When the onset of symptoms is immediate prognosis is bad, these cases are usually totally and permanently incapacitated unless improvement starts within a week of the accident. When the symptoms arise later, as a result of some inflammatory process; the prognosis is not so poor and complete recovery may occur in from six months to two years. The expectation of life is short, but if the patient has constant and skilled attention, it may be prolonged almost to normal limits. Without [illegible] care pressure sores soon develop. There usually also occurs a bladder infection which ascends sooner or later to the kidneys. Death results from toxæmia, from pressure sores, from uræmia due to the infection of the kidneys, or from pneumonia or bronchitis due to interference with proper expansion of the chest from paralysis of the chest muscles. In each of these cases death is a direct result of the injury.

Injury to spinal nerves.—Only in very exceptional cases is there any evidence of injury to the spinal nerves at the time of the accident or appearing subsequently during the course of treatment.

Late collapse of the vertebra (Kümmel's disease).—This condition as distinct from the recurrence of deformity in the vertebra after reduction is exceedingly rare and has only been seen in one out of more than a hundred cases examined by the writer. When it appears it should be treated as a recent fracture.

Tuberculosis of the spine.—There is a good deal of evidence to show that tuberculous disease of the spine may follow an injury. When it does so, the symptoms usually persist from the time of injury, although the disease may only become apparent either by sudden collapse of the body of a vertebra or by increasing pain. Where there are no symptoms of infection over a period of six months after the injury, it may be assumed that any subsequent development of tuberculous infection cannot be attributable to the accident described. Tuberculous disease of the spine will cause total incapacity for all forms of heavy work for a minimum of two years.

Pressure sores.—The common sites for pressure sores in fractures of the spine are over the sacrum and over the back of the heel. Large pressure sores over the back of the sacrum may leave a thin scar, which is liable to break down owing to the friction from the clothes. A collosity is often developed over the site of an old pressure sore of the heel, and occasionally this collosity renders the wearing of heavy boots difficult. It may, therefore, be responsible for some incapacity.

Thrombosis of veins.—Thrombosis of the femoral and external iliac vein is not uncommon, and usually occurs about the third week after injury, although it may come on at any time during which the patient is confined to bed.

Osteo-arthritis.—This is frequently described as a complication of fractures of the vertebræ; but arthritis of the joints between the articular processes as distinct from the buttressing which occurs on the bodies of the vertebræ is rare and seldom causes symptoms.

Neurasthenia.—This is a common complication of a fractured vertebra and is mainly due to the popular belief that a man with "a broken back" is completely and permanently crippled. In my practice the patient is not allowed to know that there is a suspected injury to the vertebræ, and probably for this reason no case in which this precaution was taken has developed neurasthenia. When the patient has neurasthenia it is difficult to persuade him to discard his spinal brace and so render his back muscles fit for the strain of heavy work. A neurasthenic patient therefore remains permanently incapacitated unless a very early settlement of any claim for damages or compensation that he may have is effected, and then in some cases there is improvement.

Summary

1. A fractured vertebra must be immobilised in plaster of Paris for from two to seven months. If the fracture occurs in a part of the spine that is convex forwards a plaster jacket may be used and the patient allowed to walk. If the fracture is elsewhere the patient must remain recumbent.

2. After removal of the spinal jacket a spinal brace must be worn for three months.

3. Exercise and massage and Faradism to the erector spinæ muscle should be persisted in for from six months to a year after the plaster support has been discarded.

4. In a successful case the patient is able to return to light work in from six months to one year after the accident and to heavy work in from one to two years after the accident. More than 60 per cent. of cases should ultimately become fit for laborious work, and of the remainder 30 per cent. should be fit for light or sedentary work, leaving less than 10 per cent. of cases totally incapacitated.

5. In cases in which the fractured vertebra has remained unreduced persistent pain is experienced, usually at a lower level than the fracture. The patient is also liable to recurrent strain of the erector spinæ muscle. Such patients only very rarely return to heavy work.

ALTERATION IN THE INCIDENCE OF THE GRAVIS, MITIS, AND INTERMEDIATE TYPES OF C. DIPHTHERIÆ IN MANCHESTER

AND THEIR CLINICAL CORRELATION IN A FURTHER SERIES OF 940 CASES

By D. T. Robinson, M.Sc., M.R.C.S. Dipl. Bact.
ASSISTANT LECTURER IN BACTERIOLOGY, UNIVERSITY OF MANCHESTER; AND

F. N. Marshall, M.D., D.P.H.
ASSISTANT MEDICAL OFFICER OF HEALTH FOR MANCHESTER; FORMERLY DEPUTY MEDICAL SUPERINTENDENT, MONSALL FEVER HOSPITAL, MANCHESTER

Last year we published results confirming the contention of McLeod and his colleagues (1931, 1933, *a b*) that in diphtheria there is a definite correlation between the case severity of the disease and the type of infecting organism. This view is increasingly accepted and it is evident from the figures collected by McLeod (1934) that in several areas in this country the gravis and intermediate types are at present responsible for the great majority of severe toxic cases of diphtheria. The 940 cases recorded in this paper, consecutive admissions to the Monsall Fever Hospital from the Manchester area, form a second series in an investigation which has been continuous since October, 1932. The lines of inquiry have remained the same throughout.

Incidence of the Types

Table I. compares the incidence of types in the first and second series of cases. A comparison of the figures in the two series shows a very striking change in the incidence of the types. During the earlier part of the investigation the intermediate type (54·6 per cent.) was predominant in Manchester and was as lethal as the gravis. Towards the end of 1933 the number of intermediate cases gradually decreased, but there was at the same time a steady increase in the number of gravis cases, until during the latter half of 1934 the gravis type became the prevailing or epidemic strain.

Table I

Incidence of Types in the First and Second Series of Manchester Cases

—	Cases and carriers.	Gravis.	Mitis.	Intermediate.	Atypical.	Mixed.
1934	542	129 (23·8 %)	104 (19·2 %)	296 (54·6 %)	8 (1·5 %)	5 (0·9 %)
1935	940	479 (50·9 %)	261 (27·8 %)	187 (19·9 %)	1 (0·1 %)	12* (1·3 %)

* Mixed cases. 5 gravis and intermediate; 3 intermediate and mitis; 2 mitis and gravis; 1 atypical gravis and mitis 1 gravis, intermediate and mitis.

In contrast to the gravis and intermediate types the incidence of the mitis type has fluctuated only within comparatively narrow limits and has shown but a slight total rise. In order to bring out more clearly the variation in type incidence we have prepared curves which show the seasonal occurrence of the types during the years 1933 and 1934 (Figs. 1 and 2). The curves serve to emphasise both the importance of the gravis and intermediate strains as epidemic types and the endemic nature of the mitis type.

The opinion of Parish (1934) was that strains of *Corynebacterium diphtheriæ* in London were in a constant state of flux, and this condition of variability seemed to be associated with the occurrence of many atypical strains, which apparently became less numerous as the disease increased in severity. Although, as shown above, type incidence has varied considerably in Manchester, this has not led to the appearance of atypical strains. Classification was effected without difficulty and type characters have remained remarkably stable, as witness the fact that there was only one atypical strain. This confirms previous findings in regard to the stability of Manchester types (Robinson, 1934).

Clinical Features of Cases due to the Various Types

Owing to the increased prevalence of gravis strains in Manchester we have now had an opportunity of comparing out notes of a large number of severe and moderately severe infections due both to gravis and to intermediate types. We are unable to distinguish on clinical grounds alone a gravis from an intermediate infection, either at the onset or throughout the course of the illness. Both may give rise to the gravest forms of diphtheria.

We have observed a very severe mitis infection from which the patient, a boy aged 7, died on the sixteenth day of disease.

This boy was not admitted to hospital till the fifth day of his illness. By this time membrane occluded both nostrils and extending backwards covered the nasopharynx, both tonsils, and the whole of the soft palate. He had a "bull-neck" and was extremely toxic. No petechiæ were seen on admission. He was given 40,000 units of antitoxin intramuscularly and 80,000 units intravenously. Hæmorrhage occurred a few days later from the nose and throat and bruising at the site of hypodermic injections. He died eleven days after admission.

This case was indistinguishable clinically from a severe gravis or intermediate infection. Clinical differentiation is equally impossible in cases of moderate severity. It seems justifiable to say that there are no clinical criteria to enable one to distinguish a gravis from an intermediate or mitis infection, except the fact that mitis cases usually respond better to serum therapy. It may be noted that in the fatal mitis case here described, though treated late, death was definitely due to toxæmia alone. In the two cases we have reported previously (1934) toxæmia was not prominent and but for complications the patients would probably not have died. Similarly in the small series of mitis deaths described by McLeod (1934) complications were either present or treatment was received late.

Correlation of Type with Case Severity

Table II. shows the correlation of type with case severity and deaths, excluding atypical strains and mixed infections. Table III. gives the percentage incidence of deaths and complications in 809 cases (excluding carriers and infections due to atypical or mixed strains).

These results support those obtained in our earlier investigation. They show clearly the enhanced lethal power of the gravis and intermediate strains over the mitis and the much greater tendency of those strains to cause paralysis. In 1932–33 it was our experience that the intermediates were at least equal to gravis strains both in lethal power and ability to cause paralysis. During the last year the changes in incidence of the gravis and intermediate types have been reflected in an alteration of the respective case-fatality rates, the intermediate showing a marked decline and the gravis a slight rise. The intermediate type has now become not only "intermediate" as regards biological characters and incidence, but also in respect of lethal power. This is the position which obtained at Hull in 1933 (Leete et al., 1933). The Hull figures, however, were characterised by the large number of mild gravis cases (30·4 per cent.), attributed by McLeod to a partial immunity of those attacked, whereas in Manchester only 15·6 per cent. of the gravis cases were mild.

TABLE II

Correlation of Type with Case Severity and Deaths, excluding Atypical Strains and Mixed Infections

Cases and carriers.	Hæmorrhagic.	Severe.	Mod. severe.	Mild.	Carriers.	Deaths.		
						Toxæmia.	Paralysis.	Laryng. and tracheal.
G 479	25 (5·2 %)	185 (38·6 %)	158 (32·9 %)	75 (15·6 %)	36 (7·7 %)	64	3	2*
I 187	4 (2·1 %)	39 (20·9 %)	78 (41·8 %)	47 (25·1 %)	19 (10·1 %)	13	–	1†
M 261	–	1 (0·4 %)	61 (22·3 %)	136 (52·1 %)	63 (24·2 %)	1	–	–
T 927	29 (3·1 %)	225 (24·2 %)	297 (32·1 %)	258 (27·8 %)	118 (12·8 %)	78	3	3

* Admitted 7th and 8th day of disease respectively. Tracheotomy on admission. Membrane on tonsils, larynx, and trachea. Died next day from respiratory obstruction.

† Admitted 5th day of disease. Post-measles pneumonia and laryngeal diphtheria. Tracheotomy on admission. Died 4 days later from pneumonia.

G = Gravis. I = Intermediate. M = Mitis. T = Total.

The mitis type while showing a slight increase in incidence has given no indication of an accession of killing power, the death-rate, in fact, remaining negligible. Parish (1934) thinks there is a possibility that the mitis strain might, at some future date, replace the gravis strain as the cause of high mortality. There is, however, no indication of this at present. In all those areas where the mitis strain predominates or has a high incidence the disease is comparatively mild.

TABLE III

Percentage Incidence of Deaths and Complications in 809 Cases (excluding Carriers and Infections due to Atypical and Mixed Strains)

Type.	Cases.	Paralysis.	Deaths—toxæmia and paralysis.
Gravis	443	73 (16·5 %)	67 (15·1 %)
Intermediate ..	168	17 (10·1 %)	13 (7·7 %)
Mitis	198	6 (3·0 %)	1 (0·5 %)

Dudley (1934) appears to be willing to apply the title "gravis" to the particular serological variety of starch-fermenting organisms that invaded the Greenwich Hospital School, on account of their ability to cause infections in Schick-negative subjects, but he is somewhat uncertain how far other serological groups of gravis organisms deserve this name on clinical and epidemiological grounds.

Although the Manchester gravis strains are of the same serological type as the Leeds and the Greenwich Hospital School, we do not think that there is yet any reason for reserving the term "gravis" for one particular serological type of the organisms so named by McLeod. Indeed, the available evidence seems to point to the contrary view. The serological type of gravis found in Hull is different from that of the Greenwich Hospital School, yet from the figures published by Leete et al. (1933), it appears to be fully entitled to this designation. Further, the results of Christison (1934) and Schiff and Werber (1935) in Berlin, where yet another serological type of gravis predominates, add further support to this view. It is quite possible that the various serological types of gravis described by Orr Ewing (1933) do differ in virulence (i.e., invasiveness). There is as yet no evidence on this point, but we think there is some clinical support for the view that at least three of the types are entitled to the designation "gravis" first applied to them by McLeod.

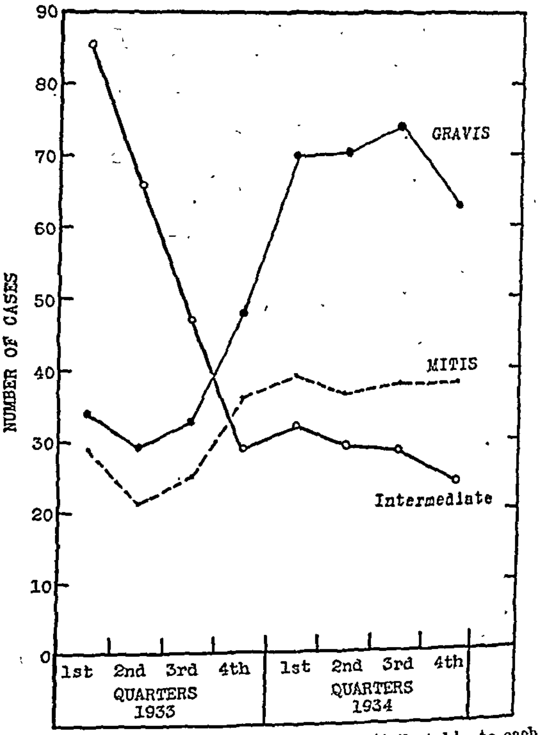

FIG. 1.—Number of cases of diphtheria attributable to each of the three types.

Laryngeal Diphtheria

During the last few years there has been a steady decline in the number of cases of laryngeal diphtheria in Manchester. Table IV. indicates the relative importance of the gravis and mitis strains in causing this type of infection. [illegible] where [illegible] is rarely limited to the [illegible] becoming involved by an extension downwards from the fauces. If, however, the larynx is the primary seat of infection there is a tendency for the membrane to involve rapidly the trachea and bronchi. Mitis infections of the larynx, on the other hand, are often limited to this site and seldom is there any concomitant involvement of the fauces or trachea. In the mitis laryngeal cases toxæmia is absent and they are dangerous only in so far as there may be an associated mechanical obstruction; whereas with gravis cases the mechanical factor is nearly always aggravated by superadded toxæmia from faucial infection.

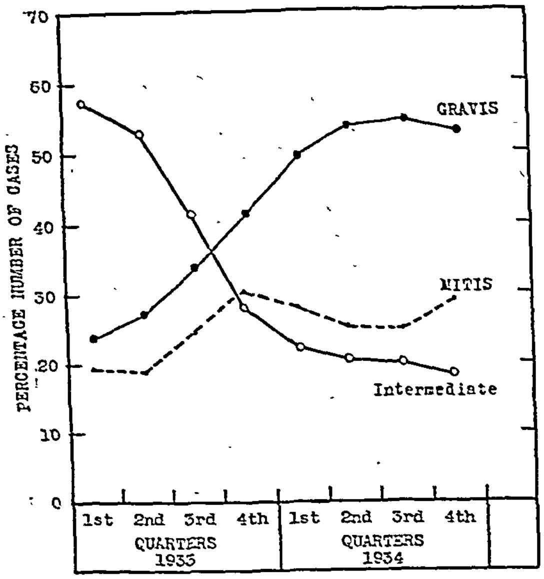

FIG. 2.—Percentage of cases due to each of the three types.

It is noteworthy in this respect that in some of the severe epidemics on the continent, notably in Berlin, laryngeal diphtheria tended to disappear and was replaced by a more toxic pharyngeal and nasal type of disease. A similar experience was noted in Leeds by Anderson and his colleagues (1931), and these workers take this fact as strengthening their concept that gravis is the cause of severe epidemic diphtheria and mitis the cause of sporadic or endemic cases which are on the whole definitely milder in their course. Our experience supports this contention.

TABLE IV

Types in Laryngeal Cases

—		Gravis.	Intermediate.	Mitis.
Faucial and laryngeal	..	9	1	8
Simple laryngeal	.. ..	2	–	11
Laryngeal and tracheal	..	2	–	–

The Time-factor in Treatment

Table V. records the average day of disease on which serum was given to those cases that recovered and to those that died from infections by the three types of organisms. It also shows the average day of disease on which death occurred. It will be noted that mitis infections were admitted to hospital approximately one day later than either gravis or intermediate infections, and yet with one exception they all recovered. In those gravis and intermediate cases that died, serum was given at about the same stage of infection as in those mitis cases that recovered. These figures show clearly that the time-factor in treatment plays no part in the explanation of the difference in killing power between gravis and mitis strains. They do indicate, however, the importance of early administration of serum, since the fatal cases received treatment on the average a day later than those that recovered.

TABLE V

Average Day of Disease on which Serum was given

—		Gravis.	Intermediate.	Mitis.
Average day of disease on which serum given to	Recoveries	3·5	3·4	4·2
	Deaths ..	4·3	4·4	5·0
Average day of disease on which death occurred		10·8	10·4	16·0

Infection in Schick-negative Reactors

Attention has been directed from time to time to the occasional occurrence of clinical diphtheria in Schick-negative reactors. This leads to questions about the exact significance of the negative Schick reaction and about the relationship between the degree of immunity indicated by this reaction and the degree necessary to prevent infection.

In a previous communication (1934) we pointed out that in our experience infections in Schick-negative subjects were always caused by gravis and intermediate strains. In other words, a negative Schick reaction seemed to be token of more complete resistance against mitis attack than against gravis or intermediate.

TABLE VI

Infections in Schick-negative Subjects

No.	Age.	Sex.	Severity.	Complications.	Type.
1	9	M.	Mild.	—	Gravis.
2	23	F.	,,	—	,,
3	19	F.	,,	—	,,
4	7	M.	,,	—	,,

10	8	M.	Mild.	—	Intermediate.
11	2	M.	Mod. severe.	—	,,
12	5	F.	,,	—	,,
13	9	F.	Mild.	—	Gravis, mitis, and intermediate.

Our observations have since been confirmed by Dudley et al. (1934) at the Greenwich Hospital School, by Underwood (1935) at Leeds, and by Parish and Wright (1935) in London.

In the present series of cases we have encountered a further 13 instances of clinical diphtheria in persons in whom the Schick reaction was negative at the onset of the illness. Twelve of these were natural Schick-negatives, and one, a nurse, had been immunised with three 1 c.cm. injections of toxoid-antitoxin floccules (T.A.F.) three years previously and had been Schick-negative when tested six months later. She was still Schick-negative when tested on the day the illness began and during the interval had been constantly engaged in nursing cases of diphtheria. The Schick toxin used in determining all these reactions was that issued by Burroughs Wellcome and Co., and has always been satisfactory. Table VI. gives details of the cases.

While these cases were for the most part mild or moderately severe, it will be noticed that 3 are described as severe and 2 of these patients died from toxæmia. In neither case was the membrane extensive on admission to hospital, being limited in both instances to one tonsil. But in spite of large doses of antitoxin given intravenously and intramuscularly (each case received in all 140,000 units) the membrane continued to spread until both tonsils and the whole of the soft palate were covered. Death occurred on the seventeenth and ninth day of illness respectively. The Schick test was performed four hours before the administration of serum.

The rest of the cases recovered without complications. It will be seen that 9 were due to the gravis type and three to the intermediate, while one was a mixed infection containing the three types. The mitis strain in this last case was, however, avirulent, so that it may legitimately be excluded. None of the other strains was tested for virulence, since in our experience avirulent gravis and intermediate strains are rare.

These results, taken in conjunction with those in Tables II. and III., make it evident that gravis and to a less extent intermediate strains possess some property, much less apparent in mitis strains, which enables them to overcome the defences even of individuals who, judged by Schick test standards, might be expected to be immune. We have previously brought forward evidence (1934) that this property is one of increased invasiveness, while Povitzky, Eisner, and Jackson (1933) are of the opinion that it is one of capacity for more rapid production of toxin. The two fatal cases in our series emphasise clearly the potentialities of the gravis strain, for in spite of the combination of adequate serum therapy and the Schick level of natural immunity the disease progressed and the patient died. The claim, often made in the past, that clinical infection in Schick-negatives is always mild can obviously no longer be upheld—certainly not in areas where the gravis strain abounds.

There is no settled opinion as to the level of antitoxic immunity indicated by the Schick test carried out with present-day materials. At the present time 1/100 A.U. (antitoxin units) per c.cm. appears to be the figure usually accepted in this country, but it has varied from 1/500 to 1/30 A.U. Parish and Wright (1935) think that 1/50 A.U. per c.cm. will probably afford protection against gravis infection, but Underwood's (1935) results show that 1/5 A.U. was not sufficient to prevent infection in one case. It is impossible to state yet the lowest figure upon which we may rely with safety. We do not know the antitoxic content of the blood of our series of cases, but it is possible that the two fatal cases had the lowest figure consistent with a negative Schick reaction. The important point that emerges is that in communities where the gravis type abounds a negative Schick reaction, according to present-day standards, at least in this country, may not always be adequate to prevent infection. The problem promises to be no less important in the future, since, as Parish and Wright (1935) remark, "there is no doubt that coincident with the increased prevalence and severity of diphtheria in many areas of England, the number of cases reported in Schick-negative reactors has also tended to increase."

The increased prevalence and virulence of the gravis type in Manchester during the last eighteen months possibly has some bearing on the fact that our present series of Schick-negative infections is more severe than the former.

Until the safety level of immunity against gravis attack has been ascertained by future work, the question arises as to the remedy to be adopted under the present circumstances. The logical procedure is of course to raise still further, by active immunisation, the antitoxic content of the subject's blood in the hope that the safety level may thereby be reached. In this respect the following case is of interest.

A nurse, aged 19 years, was found to be naturally Schick-negative on March 1st, 1934. She received 1 c.cm. of toxoid-antitoxin floccules (T.A.F.) on March 15th, 1934, and again on March 29th, 1934. On May 9th, 1934, she was found to be suffering from clinical diphtheria. The membrane covered the whole of the right tonsil. She was Schick-tested and found to be negative. There was little or no toxæmia present; 24,000 units of antitoxin were given twelve hours after the Schick test had been performed. She recovered without complications. A gravis strain was isolated from the throat.

Parish and Wright (1935) state that "individuals who are 'natural' Schick-negative reactors may be given one injection of prophylactic at the time of the Schick reading, and periodically thereafter if further experience justifies this." The case described above suggests that periodic injections are advisable, especially in nurses and others who may be more intensively exposed to infection.

Infections in Immunised Subjects

We have found 11 instances of infection occurring in persons who had received three 1 c.cm. injections of toxoid-antitoxin mixture (T.A.M.) at least six months previously. Unfortunately no Schick tests were performed after immunisation, and we are unable to record the Schick state at the onset of the disease. Details are given in Table VII. One was a mild infection, five were moderately severe, and five were severe. One patient, aged 11 years, who had been immunised four years previously, died from toxæmia in the early stages of the disease.

TABLE VII

Infections in Immunised Subjects

Pp. =palatal paralysis.

Parish and Okell (1928) showed that of 973 children who had at one time been Schick-negative 2·9 per cent. relapsed within one to seven years, and that this occurrence was almost five times more common in those artificially immunised than in those naturally immune.

It is possible that some or all of the cases in Table VII. were instances of the relapsed state, since the severity of the disease was on the whole definitely greater than in the natural Schick-negative immunes. These cases therefore do not have quite the same significance as those recorded in Schick-negatives; but nevertheless they are worthy of record in that they confirm the importance of the gravis strain as the chief agent in the breakdown of immunity. These cases might be expected to have shown an accelerated response to the secondary stimulus of the disease, but the fact that only one infection was mild makes it evident that the response was on the whole inadequate. The prophylactic used in all these cases was toxoid-antitoxin mixture (T.A.M.), since this is the only one that has so far been employed on a large scale in Manchester. Case 2 in the first series (Table VI.) is an instance of infection after immunisation by toxoid-antitoxin floccules (T.A.F.). and Underwood (1935) has reported infections occurring in people immunised by means of formal toxoid (F.T.) and toxoid-antitoxin floccules (T.A.F.). as well as in some protected by means of toxoid-antitoxin mixture (T.A.M.)

There is ample experimental evidence that a sufficiency of antitoxin in the blood will protect against any type of organism, and the ideal of active immunisation should be to produce the highest level of antitoxic immunity for the longest period of time. As Parish and Wright (1935) point out, the tendency of late to reduce the number of inoculations is hardly conducive to this end and is likely to lead to a lower level of immunity and a greater number of relapses.

Dudley et al. (1934) are of the opinion that Schick immunity is less permanent than is generally believed, but that relapse of this immunity is of no great consequence since "the subject is left in a sensitised condition and will regain his antitoxic immunity promptly on contact with the toxigenic diphtheria bacillus." A perusal of our cases indicates that there are important exceptions to this conclusion and does not support Dudley's further statement that "generally the infection is latent, rarely there may be a day or two's trivial sore-throat."

The invasiveness and toxigenicity of gravis strains in some cases apparently outstrip the response of the relapsed Schick-immune.

In view of the potentialities of the gravis strain and the fact that the Schick level of immunity by no means always corresponds with the gravis safety level, it is evident that the loss of Schick immunity is definitely to be guarded against. The only certain method of doing this would be to continue the course of active immunisation after the Schick-negative state has been reached.

Summary and Conclusions

1. A striking alteration in the incidence of the gravis and intermediate types is shown to have taken place in Manchester during the past eighteen months. The position formerly occupied by the intermediate type as the epidemic strain has now been taken by the gravis type. There is no evidence that this change was brought about by the conversion of one type into another. Atypical strains were very rare.

2. Correlation of type with case-severity again shows that the gravis and intermediate types are the cause of the great majority of severe and fatal cases. Antitoxin, even when given in large quantities on the second and third day of disease, sometimes fails to save life. Mitis infections respond better even when the serum is given later. Gravis and intermediate cases are recognised and admitted to hospital on the average a day earlier than mitis cases.

3. Simple laryngeal cases are due usually to the mitis type and danger to life is chiefly mechanical. Complicated laryngeal cases are usually due to the gravis or intermediate type. Laryngeal diphtheria has shown a steady decline in Manchester during the last few years.

4. Whether by reason of greater invasiveness or enhanced rapidity of toxin-production some gravis and intermediate strains, especially the former, are able to cause clinical diphtheria in naturally Schick-negative subjects and those who have been immunised. Such cases described in this paper are on the whole more severe than any hitherto recorded.

5. There is no general agreement as to the level of antitoxic immunity betokened by a negative Schick reaction, but there is no doubt that the level indicated by present-day standards is not sufficiently high always to prevent infection by gravis strains. The logical remedy is to increase the antitoxic content of the blood as much as possible beyond the present Schick level. This must be accomplished by artificial immunisation, since natural latent immunisation is too uncertain a factor and may fail. All negative Schick-reactors, whether natural or artificial, should receive further prophylactic inoculations. The number of inoculations required to produce the level of immunity which will give safety from gravis strains will have to be determined by future experience.

We must express our thanks to Dr. D. Sage Sutherland for granting us facilities for investigating the cases in Monsall Fever Hospital, and also to the Ministry of Health for a grant to one of us (D. T. R.) towards the expenses of the work.

MEDICINE AND THE LAW

Drunk but not in charge of a Car

THE Road Traffic Act, 1930, made it an offence to drive, attempt to drive, or be in charge of, a motor vehicle on a road or other public place when "under the influence of drink or a drug to such an extent as to be incapable of having proper control of the vehicle." There have been several decisions by magistrates as to how far a person is punishable as being "in charge" of a motor vehicle when the vehicle is in fact stationary. Last week at the Sheffield police-court a prosecution was launched where a person, undoubtedly under the influence of drink, had been shut up in a car to sleep it off. In effect the car had been treated as a police cell or hospital ward. The accused could not remember having been placed in the car, but other witnesses described what had happened. A Mr. Pearson saw him in a public-house and deemed him unfit to look after himself. With assistance, Mr. Pearson took him outside and put him in Mr. Pearson's car which was on a piece of spare ground. The car was so close to a wall that the left-hand door could not be opened, the other door was locked, the ignition key was removed, the lights were off, the brakes were on, and the car was left quite safe. Like a modern Good Samaritan, Mr. Pearson arranged with another man to take the patient home on the morrow when he had recovered; but the police found him and drove the vehicle to the police station where the accused was in so helpless a state that he had to be lifted out. The defending solicitor had no difficulty in convincing the bench that his client had been put in the car without his own knowledge and that he was unable to drive the car and had no intention of doing so. The case was therefore dismissed.

Death by Drowning

At an inquest last week a doctor who gave evidence observed that there is no justification for the popular belief that a body in the act of drowning rises three times to the surface. Some bodies may do so, but no inference can safely be drawn from the number of reappearances on the surface of the water. The specific gravity of the human body is very nearly that of ordinary water. The buoyancy of the body or of the clothes may raise a person to the surface soon after immersion; instinctive attempts at self-preservation will result in movements which may bring a non-swimmer upwards as if he were able to swim. The inspiration of water with air, desperate attempts to breathe and the inhalation of more water, cramp or shock, exhaustion and insensibility—all these are to be looked for in drowning, which is an asphyxia produced because water and not air penetrates the air-passages and lungs so that aeration of the blood is prevented. At the recent inquest the usual question arose as to marks found on the body. The relatives thought it possible that some violent blow had been struck before the body entered the water; there was, however, no reason to suppose that the marks were other than accidental. Text-book writers usually warn the student that external marks, where no explanation of their origin is established, give little help in establishing the fact of death from drowning.

Error in Death Certificate

Sir Samuel Brighouse adjourned a Lancashire inquest lately on evidence that the house physician at a hospital had signed a death certificate for a baby with a statement that it had died in the hospital when in fact it had died at its home. The coroner observed that hospitals must understand that they have to carry out their duties with proper care whether or not they are rewarded by financial payment. He found it unsatisfactory that the child should have been allowed to leave the hospital when, as the post-mortem examination showed, it had been very ill. Death was found to be due to toxæmia, an effect of infective gastro-enteritis, chronic meningitis and pericarditis. The house physician was asked why he gave a death certificate when he had not attended the child in its last illness. He replied that, when asked for a certificate, he telephoned to the Liverpool city coroner's office and related the facts to the coroner's officer who advised him that the best course was to sign. This being an application to an officer of another district, Sir Samuel Brighouse made his protest against the apparent encroachment upon his own functions. While the medical witness could perhaps hardly be expected to appreciate the technical aspects of jurisdiction, he could properly be pressed as to his knowledge of the child's illness and death. "How did you know the child was dead?" asked the coroner. "Somebody told you but you did not know. Recently I had a case where a medical man gave a certificate stating the cause of death and the person was not dead; the law ought to compel a doctor to see that a person is dead before giving a certificate." Sir Samuel made it clear that he did not blame the witness for the imperfect state of the law, but there had clearly been a serious error in stating that death took place in the hospital. The witness, apologising for his mistake, could only suggest that it was due to the fact that in all previous cases the certificates he had signed had related to deaths within the hospital.

INTERNATIONAL PHYSIOLOGICAL CONGRESS

IN LENINGRAD AND MOSCOW

THE fifteenth International Physiological Congress opened at Leningrad on the evening of Thursday, August 8th, with an informal reception in the marble hall of the Ethnographical Museum (Michailowsky Palace). The Physiological Society of the U.S.S.R. has worthy rooms at its disposal for the entertainment of its guests. As the curtains parted to admit them on arrival, the sudden view of the great hall with its vast pink marble columns and magnificent dado of green bronze, seen through a faint haze, made an overwhelming impression. The floor was thronged with people and the buffets laden with Russia's most delicious foods.

The formal opening took place the next morning in another fine building, the Uritzky Palace. Here, the hall of the former Duma was perfectly equipped for the purposes of a conference. Earphones were supplied to every seat, and by moving a plug from one hole to another the members could hear either the speaker's own voice or his speech translated into English, Russian, French, or German. This made it possible for the whole audience to follow every word.

Prof. IVAN PAVLOV, as president, welcomed the members of the Congress, and made reference to the loss physiology had suffered in the last year by the death of Sir E. Sharpey-Schafer and Prof. J. J. R. Macleod; the conference stood while Chopin's funeral march was played. Prof. Pavlov spoke in general terms, urging upon all scientists to be strong in internationalism. War is a bestial way of settling our differences and the Russian Government, he said, has declared that it will never lay hands on any foreign land.

The president of the committee organising the conference, the president of the Academy of Science of the U.S.S.R. (the aged Prof. KARPINSKY), and the president of the Leningrad Soviet all added their words of welcome and emphasised the superlative value which the Government of the U.S.S.R. attaches to scientific research.

The rest of the opening sitting was devoted to the address of Dr. W. B. CANNON of Boston. He paid special tribute to Prof. Pavlov, and congratulated him on the falseness of his prophecy, made three years ago at the Physiological Congress in Rome, when he expressed the opinion that that would be his last opportunity to address his fellow physiologists all assembled. Dr. Cannon talked first of general matters near to the hearts of all scientists: of those conditions which are unfavourable to scientific research and the discovery of the truth—a feeling of insecurity arising from political or financial causes, limitations set by hostile social establishments and interests, and general lack of financial support. Favourable conditions, on the other hand, are freedom to choose the scope of an inquiry without nationalistic limitations of expediency; freedom to pursue that inquiry without pressure to show results, which only ends in substituting anxiety for fertility of thought; and, finally, freedom for international exchange of students and ideas. As an instance of successful international coöperation, Dr. Cannon referred to his own work on the mode of action of autonomic nerves on their effector organs. Knowledge of the chemical transmission of nerve impulses has made considerable advance in the last three years, thanks to the work of investigators in Austria, Belgium, Canada, England, France, Germany, Holland, Hungary, Mexico, the Soviet Union, Switzerland, and the U.S.A. Dr. Cannon spoke further of the specific characteristics, differentiating the sympathetic mediator from adrenaline and justifying the special name of sympathin, which he had given to it in conjunction with his colleague, Z. M. Bacq.

Dr. Cannon opened the work of the sectional sittings on the following day, with an elaboration of the same theme, discussing the evidence for his suggestion that sympathin can be differentiated into sympathin *e* and sympathin *i*, the former being excitatory and the latter inhibitory. Numerous other papers in the same and allied fields were also presented, and, in all, somewhere about 500 papers were read in the various sections.

At a further plenary session of the whole conference in the hall of the Duma, on August 13th, Sir Joseph Barcroft (Cambridge) and Prof. L. Orbeli (Leningrad) gave addresses.

Sir JOSEPH BARCROFT spoke of the velocities of some physiological processes and discussed the possibility that the rate at which chemical processes occur may be a limiting factor of importance in the body. In the ordinary loading and unloading of oxygen, the chemical events take place so much more rapidly than the physical ones that the rate of the chemical phase of the reaction may be regarded as negligible. Though the rate of combination of hæmoglobin with oxygen may not be important in man, there are forms of life in which it is otherwise. In mice for instance, if the heart muscle contained ordinary hæmoglobin, it would not be possible to say that the time of oxidation of the hæmoglobin was quite inconsiderable as compared with the time of the diastole of the heart beat. The pigment in cardiac muscle is myoglobin not hæmoglobin, and the chemical reactions of myoglobin take only about one-sixth of the time taken by those of hæmoglobin; in the heart of the mouse and canary the pigment, actually, is not myoglobin but cytochrome, whose reactions are even faster. The rate of reaction of oxygenase and catalase and of carbonic anhydrase, which accelerates the conversion of carbonic acid into CO_2 and water, were also considered.

Prof. ORBELI spoke on pain and its physiological effects, discussing whether pain is perceived by the organ which perceives ordinary tactile stimuli or not, and describing various experiments carried out in his own laboratory and their bearing on the subject.

Continuation of Pavlov's Work

The time of the Congress was by no means wholly spent in the reading and hearing of papers. A great variety of other entertainments was offered, among which, particularly, visits to laboratories and scientific and medical institutions were of the greatest interest.

Naturally, of all the scientific work going on in Leningrad, that of Academician Pavlov (as his colleagues reverently call him) arouses the most curiosity. Excursions were arranged to the Leningrad branch of the All-Union Institute of Experimental Medicine (VIEM), which includes in its section of physiology a department presided over by Prof. Pavlov. Here are to be seen the specially constructed rooms and recording instruments when the work on conditioned reflexes in the dog and mouse is being continued. For the mice, whose reactions have to be measured by means of their motor response instead of by a secretory one, an ingenious cage has been devised in which the sleeping-room, dining-room, and intermediate passage are poised along the long axis of the bar of a balance, so that the dining-room descends when the mice enter it, anticipating food, and the movements of the cage are recorded electrically. The mice can distinguish between two different musical tones of which one becomes associated with the appearance of food and the other not. The possibility of converting a conditioned reflex into an instinct is still being studied.

Among the many other departments in the All-Union Institute of Experimental Medicine, Prof. E. S. London's department of physiology and pathology of metabolism was of special interest. The technique of securing cannulas in the great veins (renal, hepatic, &c.) of the abdomen has been perfected so that the cannulas can be left in position for months at a time and the blood of the dog can be directly investigated, as it goes to or from a given organ, after some particular procedure. Such a technique opens up a wide field of investigation.

Another direction into which Prof. Pavlov's work has led him is into the field of psychiatry. At the Psychiatric Polyclinic a section of 25 beds has been set aside for the purpose of investigation. Every fortnight Pavlov himself selects cases suitable for study; the two lines which are being investigated at present are epilepsy and the circumstances which condition an attack, and the stupor and delirium of schizophrenia. The cases and technique were demonstrated by Dr. IVANOV-SMOLENSKY.

In another institution, groups of 8 normal babies (4 boys and 4 girls) are selected from among orphans at birth and brought up together till about the age of 3 years, when they are adopted. On these children the development of conditioned reflexes is also studied under Prof. Pavlov. Several visitors remarked that it seemed well worth while to be an orphan, so admirably were the children cared for.

At Koltuchi, about an hour's run in a car outside Leningrad, a new biological station is being provided for Prof. Pavlov. Scientific work in it has hardly began as the buildings are scarcely completed. Here are Pavlov's own dwelling-house and laboratories, with palatial accommodation for the experimental dogs and monkeys (chimpanzees) and a very numerous staff to care for them.

Nutrition and Malnutrition

Nutrition is a subject which concerns the U.S.S.R. deeply and intimately, and those engaged in its investigation looked forward eagerly to the visit planned to the Central Institute of Nutrition in Moscow.

No very important material was presented to the sectional discussions in this field, but one impromptu communication was certainly of major interest and the paper of Prof. L. A. Tcherkess (Odessa) on "alitoxins" was stimulating.

At the International Conference on Vitamin Standardisation, held in London last summer, a great difficulty was encountered in connexion with the establishment of the standard for vitamin D, the antirachitic vitamin. The standard material adopted already in 1931 was a solution of irradiated ergosterol, but as the result of very numerous experiments it is now clear that all sources of vitamin D have not the same potency relative to one another when tested on the rat, as they have when tested on the chicken. What the position is with regard to man is still uncertain. During the Conference in Leningrad, Prof. Agnes F. Morgan (Berkeley, Calif.) presented a paper showing the comparative effect, on young rats receiving a complete diet, of large doses (4000 international units daily), of vitamin D derived from irradiated ergosterol, a tuna-liver oil concentrate, or a concentrate from cod-liver oil. The growth performance, serum-calcium level, ash content of the bones, and calcium content of the kidney were estimated as criteria of toxicity, and it was found that all the results showed that the phenomena of hypervitaminosis were much more definitely exhibited by the rats receiving irradiated ergosterol. This was evidence in favour of the existence in fish-liver oil concentrates of vitamin D in a form different from that which is produced by the ultra-violet irradiation of ergosterol.

In comment on this communication Dr. H. A. Weidlich (Danzig) reported that it had very recently been found in the laboratory of Prof. Windaus that an antirachitic substance can be derived from other sterols besides ergosterol, which have two double bonds in the second ring, such as cholesterol and stigmasterol, and that the antirachitic substance derived from cholesterol is as potent for chicks, in rat dosage, as cod-liver oil is.

The publication of this work will be eagerly looked for, and if it is fully substantiated it will probably lead to a rearrangement of the admittedly very unsatisfactory situation with regard to the international standard for vitamin D.

Prof. Tcherkess showed mice suffering from a severe dermatitis of nose, ears, and tail produced on a diet containing various uncooked cereals or legumes. The symptoms were not cured with yeast and were attributed by Prof. Tcherkess to toxins in the foodstuffs; but that the dermatitis is one in any way connected with the dermatitis of pellagra would appear doubtful.

Factories, Nurseries, and Palaces

Besides seeing laboratories and institutions, many members of the Congress visited factories, day nurseries, homes of rest for tired (but not sick) workers, medical and welfare centres, and a great variety of the activities controlled by the State. Many of these were extremely impressive, the main difficulty being to ascertain to what proportion of the population the benefits and services as yet applied. Special arrangements were made to open, as often as was necessary, the treasury in the Hermitage Museum, where were locked up the famous collection of Scythian gold ornaments, so that very many visitors were able to enjoy this unique sight.

Besides these visits of small parties to such a variety of interesting places the hospitable Russians arranged two mass migrations out of Leningrad, of the whole conference, once to Peterhof and once to Dietskoye (ci-devant Tsarskoye) Selo. On the evening of August 10th over 1000 of the 1500 members were carried out, in 200 motor-cars, an hour's drive into the country, welcomed all the way with hand-waving and cheers. Peterhof must have been used by the Czars to impress their guests, and the remark was overheard that here alone was excuse enough for a revolution. Palaces of enormous magnificence, fountains that far outsprayed the *grandes eaux* at Versailles, gilded statues and gorgeous furnishings were revealed continuously for more than two hours. In the reception-rooms of the palace hundreds of candles were specially lit to give the physiologists a glimpse of the palace's appearance under the old régime. Finally, when the long lingering daylight had gone at last, the fountains were floodlit in many colours.

In the excursion to Dietskoye Selo, the palace containing the private rooms of the Romanoffs was first shown. Everything was still in position, the walls being covered with the Empress' personal photographs. A banquet was served in the Cameron gallery of the Catherine Palace and the scene cannot have differed greatly, save in the humble attire of the guests, from a similar occasion in the days of the Czars. The party ended with fireworks, making lovely effects on trees and water.

The next day the Congress ended at Leningrad and the members departed in a thunderstorm, which flooded the streets six inches deep and littered them with the consequent disruption of the wood-paving. Till then the weather had been perfect and many will remember Leningrad as the city of wonderful sky effects.

In Moscow

Arrived in Moscow last Saturday, the Congress met again in plenary session, for its final sitting, in the hall of the conservatory of music. Addresses were given by Prof. L. Lapicque (Paris) and Prof. A. Ukhtomsky (Leningrad). Prof. A. V. Hill (London), as vice-president of the meeting, reported the suggestions which had been made to the international committee with regard to the next meeting in 1938. An invitation had been received from Prof. Hess, in the name of the Swiss Physiological Society, to hold the meeting in Zürich, and an intimation from the Hungarian physiologists that they would like to welcome the Congress in 1938 or 1941. The international committee received the communication from Hungary very sympathetically, but since 1938 would be the jubilee of the conference, the first one having been held in 1889 in Switzerland, it was felt that Switzerland would be a very appropriate place.

Various modifications in procedure were suggested for future congresses, and it was announced that Prof. A. V. Hill was to be permanent secretary to the international committee.

Finally, Prof. Hill called upon Prof. G. Barger (Edinburgh) to return the thanks of the Congress to Prof. Pavlov and the organising committee. Prof. Barger expressed his feeling of veneration and affection directly to Prof. Pavlov in German. "Sie sind," he said, "facile princeps physiologorum mundi." He spoke further of the rivalry that there had been in Rome between physiology and ancient monuments; but here in Russia the rivalry was not with the past, but rather with history in the making, even with the chance of a glimpse into the future. Other words were added in English, French, German, Italian, Spanish, Swedish, Dutch, and Russian, so that all felt that they were taking part in expressing their gratitude for the charming welcome which had been prepared for them.

Hertford Hospital, Paris.—The response to the Silver Jubilee appeal on behalf of this hospital now exceeds £8000.

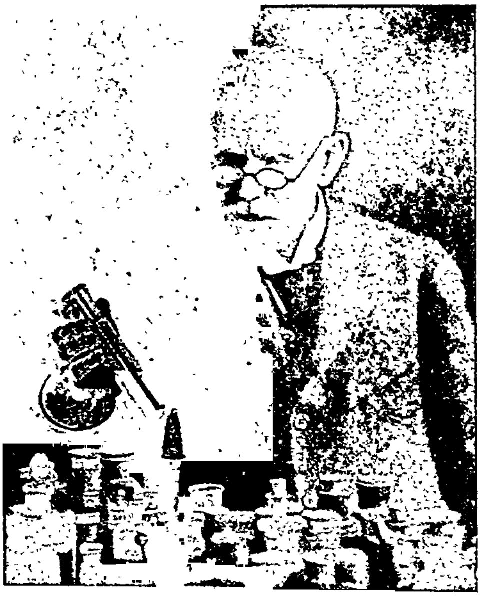
New Hospital for Newcastle-on-Tyne.—A new hospital, which will cost £15,000, is to be built in the grounds of the Home for Incurables at Spital Tongues, Newcastle, to replace the original Holy Jesus Hospital in City-road. The old institution cannot be altered to meet modern requirements.

PAUL EHRLICH

1854–1915

TWENTY YEARS AFTER HIS DEATH

[We owe the following reminiscent memoir of Paul Ehrlich to Miss Martha Marquardt, who was formerly and for a long time his secretary and whose detailed book concerning him was reviewed in The Lancet at the time of its appearance in 1924. She reminds our readers that 20 years have passed since his death at the age of 61, and that the twentieth anniversary of that death occurred on Tuesday last, August 20th.]



Ehrlich in his laboratory.

Paul Ehrlich, the famous inventor of the remedy 606, or Salvarsan, had he lived, would have been 80 years old on March 14th, 1934. And now 20 years have passed since his death. But 61 years of age, he had been summoned much too soon to eternity. Those standing on a pedestal, worshipped from afar, do not always stand the test in private life. Paul Ehrlich, among the world's greatest men was the most lovable human being, of great simplicity and sweetness of nature, liberal and broad-minded in viewpoint, always ready to support and encourage especially those engaged in scientific pursuit, charitable without limits. Born in Strehlen, Silesia, he was a descendant of a Jewish family, of which his cousin, the pathologist Carl Weigert, was also an offspring. His parents were innkeepers, but while his mother attended to business his father was given to meditation and the discussion of philosophical problems. At school, the boy Paul did not distinguish himself, although he liked Latin on account of its logical structure; when at college at Breslau he dreaded examinations, and during all his life he had the greatest sympathy with poor examinees. In his leaving examination the proposed thesis was to write an essay on Life as a Dream, and young Paul argued that life depended on the normal process of oxidation, that the activity of the brain is such a process, and that the dream also is a sort of oxidation, a fluorescence of the brain. This his examiners considered as a joke, and had it not been for his excellent Latin he would have failed. As a student Ehrlich followed up his own ideas and attended only such lectures as specially interested him. He was the first to work on aniline dyes when these were brought out by the German factories in the latter part of the past century, and a dissertation at the time, treating largely of the subject, of which nothing was known by anyone, and which he himself must have forgotten, was not discovered until after his death. His pioneer work on the microchemical relation of the dead and living tissues to dyestuffs was a consequence of these studies. When Robert Koch discovered the tubercle bacilli, it took Ehrlich but 24 hours—of close experimental work, to be sure—to find a dyestuff reaction necessary to demonstrate the presence of the bacilli, and the test is still largely in use in laboratories. Other dyestuff reactions in great number, due to his work, are found useful in medical differentiation, while his studies of toxins, of the chemistry of immunity, and his ingenious "side-chain theory" made his name famous. The discovery of salvarsan drew the attention of the world in general upon him, and stands out as his greatest therapeutic achievement.

Ehrlich was gifted with an infinite capacity for work, impatient but kindly, he was always pressing forward eagerly to his goal; yet he performed his experimental work with the simplest of apparatus. The outfit of his laboratory consisted of innumerable bottles of dyestuffs and reagents, scattered in a seemingly unintentional manner on an immense working table—only he himself knew their significance; for the rest his equipment was completed by a Bunsen burner, a few test-tubes, running water, and large sheets of white blotting paper on which he could watch the colouring of dyestuff solutions resulting from the test-tube experiments as they were poured out. His intuition enabled him to draw from a simple experiment bold, if not audacious, conclusions offering the most promising lines of further research. He used to say that he could just as well, if necessary, work in a barn. In fact, his first Institute for Serum Investigation in Steglitz, near Berlin, before going to Frankfort, consisted of an old barn and an old bakery, primitively fitted out for his purposes. One of his mottoes was "Much work, little publication, no preliminary communications, and no guesswork," and he followed it exactly in his devotion to progress in medical science. Salvarsan was discovered in 1907; two years of careful animal experimentation and another year of clinical testing under minutely controlled conditions followed before, in 1910, the results were published. In not quite five months the drug could be manufactured on a scale sufficient to allow it to be put on the market, but 65,000 free samples were distributed gratuitously by Ehrlich to the hospitals and doctors assisting in the first clinical tests. Though apparently in contradiction to what has been said, Ehrlich always pointed out that salvarsan had come into being merely as a by-product of a research started with purely theoretical aims; and Ehrlich's whole career gives striking proof of pursuit of knowledge for its own sake.

In my biography of him [1] I have told of his many idiosyncrasies which endeared him to his friends and assistants. He would explain his theories with diagrams and drawings which he would chalk up on the table, the door, the floor, his cuffs, and even on the soles of his shoes while talking about his work. He had a special love for popular music, and while in his laboratory at work he liked to hear a barrel organ playing outside. He loved bright-coloured and intensely fragrant flowers, gaily coloured pencils and cards for making notes, while he played a special game of patience which never came out. He could watch birds, insects, or a tiny plant on the bare stump of a tree for hours. There were two luxuries he allowed himself: first, good cigars of great strength which he puffed while making notes or dictating lectures or letters and which were laid down or forgotten only when experimenting over the Bunsen burner. Secondly, he bought books, making notes and markings in the margins of most of them while reading. When asked to return a borrowed book—like many others he forgot to give them back—he had to buy new copies because the pages of those which had been under his hands might be covered with chemical notes. And for leisure he preferred reading detective stories, though these could not distract his thoughts from scientific matters, judging from the notes and sketches with which he would adorn both covers and contents. Knowing his taste, Sir Arthur Conan Doyle would send his "great colleague" copies of the "Sherlock Holmes" books, while on Saturday evenings, when a 30-pfennig copy of a detective magazine appeared with fantastic pictures on the cover, neither the card-playing nor music could interest him.

---

[1] Paul Ehrlich als Mensch und Arbeiter (Deutsche Verlagsanstalt, Stuttgart, 1924).

Numerous honours were bestowed upon him, and he shared the Nobel prize in 1908 with Prof. Metchnikoff. He had medals and titles, but nothing conferred upon him did he enjoy as much as his honorary membership of the German Chemical Society. Failing health and the world war clouded the last year of Ehrlich's life. He was deeply distressed over the war, convinced that it should have been avoided and anticipating many of the troubles it would bring to all. The break in his scientific coöperation with friends abroad was a painful experience to his true and kind heart. He died on August 20th, 1915, of an apoplectic stroke, truly a victim of the world conditions, the cruelties of which preyed on his mind. Had he been spared some years, probably more great contributions would have been made by his genius to medical science; but he has inspired with his ideas chemists, experimental pathologists, and clinicians the world over, who are following in the footsteps of a great benefactor of mankind.

IRELAND

(FROM OUR OWN CORRESPONDENT)

PUBLIC HEALTH WORK IN CORK

THE two most striking features of Dr. J. C. Saunders's report as medical officer of health for Cork are his observations on diphtheria and on milk. Last year there were 113 cases of diphtheria in the city with 25 deaths—a case-mortality of 22·1 per cent., compared with 12·8 per cent. in 1933 and 20 per cent. in 1932. For the past six years Dr. Saunders has been very active in carrying out immunisation against the disease, and no less than 12,000 children have been immunised. He is able to report that, notwithstanding the severe type of diphtheria prevalent, not a single immunised child has died of the disease, whereas during the same period over 180 untreated children have died of it.

milk Dr. Saunders finds that the proportion

shows a tendency to increase. In 1934 of 2 ordinary samples no less than 72·2 per cent. w "dirty," and 35·4 per cent. "very dirty"—that to say, grossly contaminated with dirt of ev description—manure, stable dust, road dust. T pasteurised milk was also unsatisfactory. The aver bacterial count over the whole number of samp of pasteurised milk examined was 244,000 per c.c which is more than twice the number (100,0 ordinarily taken as permissible. Dr. Saunders su up his survey by saying that there is evidence "almost universal carelessness and lack of hygi methods in the production of the ordinary m supply to the city." One may hope that there be some improvement as a result of the legislat recently passed.

On some other points Dr. Saunders can cl progress. Typhoid fever had dwindled to neglig proportions. The death-rate from pulmonary tu culosis was 1·34 per 1000 of the population, lowest figure recorded. The infantile mortal rate was 72·3 per 1000 births, the figure for previous year being 89.

PROPOSED TREATMENT OF EARLY INSANITY

Dr. O'Connor Donelan, resident medical sup intendent of the Grangegorman Mental Hospi Dublin—the principal public mental hospital Ireland—made an interesting proposal to the co mittee of the hospital last week. He suggested t mental clinics should be established at one or m of the clinical hospitals of Dublin, on the und standing that a medical officer of his staff sho be deputed to attend at those hospitals for a speci period once or twice a week, for the purpose of as ing the hospital physicians in the diagnosis treatment of such patients as might present th selves. Such a scheme should be combined with admission of voluntary patients to mental hospi He believes that this plan offers the best cha of dealing successfully with mental illness in early stages. The committee agreed, and deci in the first instance, to communicate with two the city hospitals with a view to its adoption.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

PLIGHT OF THE MEDICAL PROFESSION

IN a presidential address to the Royal Societ Medicine of Budapest, Prof. Tibor Verebély la spoke in moving terms of the anxious responsib which leading members of the medical commu felt for the status of their profession. Many of colleagues were finding it impossible to earn a de livelihood, while in the medical schools the tea were full of sympathy for students who were trying to assimilate an excess of information an the same time to support themselves. It was wonder that so many of them failed to finish courses. Prof. Verebély spoke with distress of complaints which daily reached the Board of Medical Association and which showed the strai which some unfortunate medical men had driven in desperation.

TWO PROFESSORS HONOURED

Marble statues have been erected in Budape memory of two teachers at the University. Ign Hirschler was famous as professor of ophthalmo and Vilmos Tauffer as an obstetrician and gynæcologist. Soon after his tragic death I gave some account in THE LANCET of Prof. Tauffer's work (1935, i., 766). The statues have been erected through the generosity of Leo Goldberger de Buda, a silk manufacturer.

RETIREMENT OF UNIVERSITY PROFESSORS

Under the rule that university professors must retire at the age of 68, the University of Budapest has said goodbye to five professors whose places it will be hard to fill. Baron Alexander Korányi, professor of internal medicine, Emile de Grosz, president of the International Association for the Campaign against Trachoma and professor of ophthalmology, Stefan Tóth, professor of obstetrics and gynæcology, Géza Illyés, professor of surgical urology, and Charles Schaffer, professor of neurology and psychology, have all resigned from their chairs.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

BATHER'S ITCH

SCHISTOSOME dermatitis, commonly called bather's itch, was described first by Cort in the United States (1928) and has since been reported from Wales[1] and from France. The cause has been shown to be the free swimming larval forms of certain species of schistosomatidæ. In the course of their normal life cycle these larvæ penetrate the skins of certain waterfowl or small mammals and find their way through the circulatory system to the liver. When they penetrate human skin they appear to lose their way and to die, the proteins so released giving rise to a skin allergy.

An essential part of the life cycle of these schistosomes is spent in snails which thrive on shallow beaches. In the Michigan lakes *Limnæa stagnalis* and *L. palustris* are found to be hosts to the embryonic forms of schistosoma. Where the shore line slopes rapidly to a depth of 20 feet or more snails are scarce and swimmers itch is not likely to be met with. Where the beach is shallow collectors in bathing dress or wading boots are able to find the responsible snails and to warn bathers of the danger. It has recently been found that on Burt Lake, Michigan, cases of dermatitis were occurring among bathers although no snails could be discovered on the beach. The solution of this puzzle was reached when Mr. Glading and Miss Hughson donned helmets of the kind devised by Mr. William Beebe and explored the deeper water. Snails were then found in abundance at depths from 6 to 18 feet.

No way of eliminating either the cercaria or the snail hosts has yet been devised for large bodies of water. All that can be done is to map the snail beds and warn would-be swimmers of the risk.

WATER-BORNE AMŒBIC DYSENTERY

In connexion with the investigation made by the U.S. Public Health Service into the epidemic of amœbic dysentery that originated in Chicago in 1933 an interesting supplementary study[2] has been made into an outbreak of enteric infection following the
big stockyard fire in Chicago in May, 1934

PUBLIC HEALTH

Manchester Hospitals

THE liaison between the voluntary and municipal hospitals in Manchester is likely to become more intimate. Some months ago the medical officer of health, Dr. Veitch Clark, submitted a scheme for reorganising the specialist services of the municipal hospitals, in which he drew attention to the necessity of "interlacing" the consulting staff with that of the voluntary hospitals. His scheme provided that all acutely ill patients in corporation hospitals should be seen on admission by specialists who would remain responsible for their diagnosis and subsequent treatment. Obviously the appointment of these consultants was a matter in which the Royal Infirmary and other teaching hospitals were interested and the public health committee has now approved the setting up for the purpose of a joint hospitals advisory board. This board will consist of ten members of the health committee, including the medical officer himself, six members of the voluntary hospitals statutory committee, and five nominees of the university. Of these five it is presumed three will be the occupants of the chairs of medicine, surgery, and obstetrics, and one the vice-chancellor of the university, Prof. J. S. B. Stopford, whose independent position would make him an admirable chairman. The scheme would entail a regrouping of hospitals; the Withington municipal hospital for instance would be associated with the Royal Infirmary, St. Mary's Hospital, and the Eye Hospital; Crumpsall municipal hospital with two other voluntary hospitals, Ancoats and the Northern. In course of time no doubt this would lead to the concentration of grave cases in certain hospitals and to some selection of patients, although it is realised at the outset that the clinical policy of the Royal Infirmary could not be altered without much thought and consultation with the various groups of supporters. The chairman of the public health committee, Councillor R. G. Edwards, has pointed out that the setting up of such a board would go further than the clause in the Local Government Act, 1929, enjoining consultation between the local authority and the voluntary hospitals in the area. It would, he hoped, work out so that no patient would have to wait for treatment at any hospital, voluntary or municipal. Mr. Walter Coppett, chairman of the Royal Infirmary, has expressed a similar view, and especially welcomes the introduction into municipal hospitals of the principles of administration which have been so successful a part of the voluntary hospital system. Besides reducing the long waiting-lists, the scheme would lead, he thought, to further search for new methods of treatment and to improvements in teaching. The scheme will now go forward to the city council as an agreed measure.

Sequel to a Pilgrimage

Following a pilgrimage to Lourdes undertaken by 1100 people from all parts of Scotland, a total to date of 75 cases of typhoid fever has been recorded. The pilgrims left Glasgow in the *Athenia* on July 12th for Le Verdon and returned home on the 23rd. On August 5th a case of enteric fever was removed to a Glasgow hospital, and on the following morning a second case was reported by the medical officer of health for Dunbartonshire. Other cases of illness were then discovered, the onset being between July 27th and August 10th, most of them nearer the later date. Prompt action by the health department of Glasgow in following up all the pilgrims, together with the crew of 327, led to the discovery among the former of 38 cases in which bacteriological confirmation of a typhoid infection was obtained. After consultation with the Department of Health, the Glasgow M.O.H. undertook to supply a list of pilgrims to all local authorities involved, which has resulted in 37 further cases of fever being brought to light in the counties and burghs of Scotland. In view of a second pilgrimage to leave Liverpool on July 24th and Dublin on the 25th by the same ship and the same route, the Ministry of Health determined to supply medical officers of health with the names and addresses of pilgrims, and to request that any cases of typhoid occurring in England and associated with this voyage should be intimated to them. So far, most of the cases have been in women, probably because they were in the majority. The ship's crew were not affected; they remained on board the ship at Le Verdon, and only one visited Lourdes.

The range of dates of sickening is consistent with infection having taken place "somewhere in France," but the common source of infection is difficult to determine on the evidence at present available. Food and drink were partaken at an intermediate station where, the pilgrims state, there was a plague of flies and water was available of two different qualities—viz., "eau potable" and "for other purposes." Investigation is being made by the Glasgow M.O.H. to ascertain all possible sources of infection, whether carrier or vehicle (fruits, vegetables, meat, water, insects, &c.), from histories obtained from the pilgrims.

The infection is of a severe type, four deaths having resulted to date: two in Glasgow and two in Lanarkshire. The outstanding clinical features are high fever, headache, backache, epistaxis, rose spots, and constipation; a number of the patients have been regarded as suffering from lumbago, influenza, or sun-stroke until the visit of the local health officer. A close observation is being kept on all home contacts to prevent the spread of infection among the community by missed ambulant cases or carriers, and on all persons receiving fomites, water, and foodstuffs from the returned pilgrims.

Enteric infection has been fairly prevalent this year in Scotland, but mainly of the paratyphoid group. A fresh strain of *Bacillus typhosus* has been introduced into a community the epidemic constitution of which is vulnerable.

Food Poisoning in North London

Last week the St. Pancras coroner, Mr. Bentley Purchase, opened an inquiry into the death of four middle-aged persons, a man and three women, who had died within a few days of eating a vegetarian dish known as nut meat brawn. The health authority of St. Pancras was able to identify the poisonous material in a supply of this food, the sales of which were promptly stopped, and the outbreak controlled. The symptoms in all four cases suggested poisoning by a preformed toxin rather than any of the commoner forms of bacterial poisoning, and suspicion naturally turned on botulism. The inquests were adjourned until to-day (Friday). But the characteristic symptoms which were at once correctly interpreted by the practitioner who was called in, and the laboratory findings, leave little doubt that *B. botulinus* was the source of the toxin.

OBITUARY

JOHN ANDERSON, D.S.O., M.B. Aberd., F.R.C.S. Edin.

Prof. Anderson, who died on August 17th at Dundee after a long illness, was a surgeon of wide repute and a citizen revered throughout lowland Scotland. John Anderson, who bore his father's name, was born in 1886 at Macduff, Banffshire, and graduated in medicine at Aberdeen in 1908. He then began his lifelong association with Dundee by serving as house surgeon at the Royal Infirmary, after which he spent two wander years, first as surgical officer at the Beckett Hospital, Barnsley, and then at Tübingen and Berlin. On his return to Dundee in 1911 he was appointed to the surgical staff of the Infirmary, of which he was at the time of his death senior surgeon, having two years ago succeeded the late Prof. Turton Price in that office and in the university chair of surgery. He also held many other surgical appointments in Dundee and Perth and was consulting surgeon in surgical tuberculosis to most of the hospitals in the area. As surgeon to King's Cross Hospital and Ashludie Sanatorium he had the opportunity of helping to frame the policy of an enlightened local authority.

[*Photograph by Drummond Young*

PROF ANDERSON

His career was interrupted early by the outbreak of war, and joining the R.A.M.C. in 1914 he was made surgical specialist to the 20th Casualty Clearing Station in France and served for a time as consulting surgeon to the 3rd Army. He was twice mentioned in dispatches and in 1918 was awarded the D.S.O. Not long ago, in a public lecture at University College, Dundee, he reminded his hearers of the conditions under which surgery was done in the early months of the war, and threw light on the unparalleled opportunities for resource and craftsmanship under circumstances which might have dismayed anyone of lesser mettle. He was a member of a team of six surgeons working in shifts of 15 hours by electric light generated by a motor-cycle engine and shaded by petrol tins; it was then, he said, that he came to understand something of the difficulties which Joseph Lister had to surmount. His war experience led him to write in an official book on the treatment of cranial injuries and in current medical journals on penetrating wounds of the chest and unusual fractures of the patella. When he returned to civil practice it was the same story of energy, assurance, and conscientiousness, for no one without these qualities could have come to fill the place he did in the life of the community. It was his conviction that the State would play an increasing part, financial and administrative, in the hospitals of the country, and he wished to be forearmed for this change. The chairman of the hospital board attributes much of the success of the Dundee Infirmary to his wholehearted coöperation. It was, he writes, Anderson's great interest in life; rich or poor, simple or otherwise, everybody was the same to him and he was the same man to all. He was very kindly and humane, and his presence was an unfailing reassurance at anyone's bedside.

Anderson kept up his habit of foreign travel and studied the technique of many continental as well as British clinics. The application of high-frequency current to surgery early claimed his attention; it was after working for 15 years with a small Schall apparatus that he related his experience at a meeting of the Royal Society of Medicine, insisting that surgical diathermy had a wider application in treatment than was then realised in this country. His results with radical removal of breast cancer by the diathermy knife had shown him that primary union was the rule and the stay in hospital shortened. He used the cutting current for all biopsies because it eliminated the risk of spreading cancer cells, and the method had enabled him to remove cancers of the tongue which were pronounced inoperable. His address which was followed with the closest attention led a number of his hearers to try the method for themselves.

Prof. D. P. D. Wilkie writes: "Those who had the privilege of knowing John Anderson mourn to-day the passing not only of a gifted surgeon, but of a singularly attractive personality. Combined with a great capacity for hard work he had a flair for friendship and enjoyment and his ready sense of humour and boyish outlook made him a gay companion and a genial friend. In the war a very gallant army surgeon, he brought back into civil surgery more fully than almost any of his comrades the useful lessons of war-time experience. A born traveller and a ready assimilator of new ideas he was perhaps more conversant with the practical aspects of American and European surgery than any other surgeon in this country. As a member of the Moynihan Chirurgical Club he was a welcome and a regular attender at nearly every meeting and, late or early, some form of rapid transport would always bring him to the meetings. Living intensely, with a high sense of duty and a spirit always greater than his bodily physique, Anderson crowded into his comparatively brief career as surgeon a wealth of sterling work and no less of kindness and of friendship. He leaves behind him a very happy memory of a keen, debonair and handsome surgeon, a sportsman, and a true and loyal friend."

In private life Prof. Anderson used his scanty leisure for shooting and angling expeditions in the Highlands. He married in 1930 the only child of Maj.-General E. G. Sinclair-Maclagan, who is left with two young children.

HUGH WALKER, M.A. Glasg., M.B. Edin., F.R.F.P.S. Glasg.

Dr. Hugh Walker, who died in a Glasgow nursing-home on August 9th in his seventieth year, was well known in western Scotland as an ophthalmic surgeon. Eldest son of Dr. William Walker, who practised for nearly 60 years in Pollokshaws, he went to the Old High School in Elmbank-street, Glasgow, and from there with a bursary to Glasgow University where he took his M.A. He then went on to Edinburgh for his medical studies which he completed in 1893 with first-class honours in the M.B. and the Beaney prize in anatomy and surgery. After a year or two in general practice he discovered his ophthalmic bent. He was a good mathematician and had attended Tait's course of physics in Edinburgh, and on a visit to Berlin acted as assistant to Prof. C. R. Greeff, and undertook the translation of his Guide to the Microscopical Examination of the Eye, which went through three editions. From pathologist to the Glasgow Ophthalmic Institute and assistant to Dr. Maitland Ramsay, in 1903 he became surgeon to the ophthalmic department of the Victoria Infirmary, only retiring four years ago on reaching the age limit. During the war he was attached to the Serbian army as eye specialist learning the Serbian language and acting as interpreter—he already knew German well; for his services he was decorated with the Order of St. Sava. On his return to Glasgow he resumed private practice with the late Dr. Freeland Fergus, and was at work until a month or two ago. Dr. Walker was employed as ophthalmic surgeon by the Glasgow school board; he was himself a member of the Eastwood board and keenly interested in its work. His colleagues found him always ready with helpful advice, and he had a kindly smile for everyone. He is survived by his wife, a sister of the town clerk of Edinburgh; his younger brother, Dr. W. Kerr Walker, is still in practice in Pollokshaws.

CORRESPONDENCE

NOMENCLATURE OF CORPUS LUTEUM HORMONE

To the Editor of THE LANCET

SIR,—During the past year the progestational hormone has been isolated from the corpus luteum in pure form and its constitution established. Heretofore two different names have been used for this hormone (progestin, luteosterone). For the sake of international uniformity we agree to use hereafter in the scientific literature only the name *progesterone* for the pure hormone. As is known, the pure hormone exists in two different forms, one melting at 128° (uncorr.) and the other at 121° (uncorr.). The higher melting form (Compound B of Wintersteiner and Allen [1] and Compound C of Slotta, Ruschig, and Fels [2]) will be known as α progesterone and the lower melting form (Compound C of Wintersteiner and Allen and Compound D of Slotta, Ruschig, and Fels) as β progesterone. We hope that these names will be generally accepted.

We are, Sir, yours faithfully,

W. M. ALLEN (Rochester, N.Y.),
A. BUTENANDT (Danzig),
G. W. CORNER (Rochester, N.Y.),
K. H. SLOTTA (Breslau).

SKIN TESTS IN WHOOPING-COUGH

To the Editor of THE LANCET

SIR,—In your last issue Drs. Paterson, Bailey, and Waller describe a skin test, using Sauer's vaccine, designed to show susceptibility to, or immunity from, whooping-cough. At Dr. Paterson's suggestion I have been using the same test on children in the wards of the Hospital for Sick Children, with results similar to theirs. So far 105 children have been tested, of whom 53 had had whooping-cough, and 52 had apparently never had it. Of the 53 who had had it, 52 (98 per cent.) gave positive reactions, while of the 52 who had never had it, 19 (27 per cent.) reacted positively, and 33 (63 per cent.) negatively.

Abortive and subclinical infections are common in other infectious fevers, so it is not surprising that 27 per cent. of those who denied ever having had whooping-cough should give positive tests. With this in view, the histories of 18 of the 19 children were probed into more deeply. (*a*) Two had never had a cough. (*b*) Five gave histories of having had "bad bronchitis" lasting 1–2 months, but their coughs were not spasmodic, not worse *at night*, and not associated with sickness. (*c*) Eleven had had coughs that were suggestive of *attacks of whooping-cough* without the whoop. The following are examples:—

1. A boy, aged 2½, whose brothers had had whooping-cough last year. At the same time he had had a cough, occurring *in spasms which were worst at night and left him red in* the face. He retched, but was not sick. The cough lasted only 2–3 weeks, and he never whooped.

2. A girl, aged 5½, had a severe spasmodic cough 1½ years ago, which was worse at night. She was often sick at the end of a fit of coughing, but never whooped. The cough lasted only 7–10 days.

Histories such as these afford grounds for believing that the children had had abortive attacks of whooping-cough; but this can never be more than a supposition, *until it* can be proved that they do not develop the disease when exposed to infection.

The criteria employed were the same as those used by Dr. Paterson and his collaborators—i.e., the test was not considered positive unless the area of erythema was larger than 1 cm. The test was read at the end of 24 hours. It must be admitted that about 10 of those who had had pertussis gave tests which were only just positive, but I think that this was due to using an insufficient dose (0·05 c.cm.). Equivocal results were not obtained when 0·1 c.cm. was injected. The only case which gave a negative test with a positive history was a boy with acute nephritis, uræmia, and gross œdema, who died a fortnight later.

These results and those of Dr. Paterson do not agree with those of earlier workers. Orgel (Arch. of Pediat., 1929, xlvi., 149) tested 1050 children, and found that 82 per cent. of those with pertussis, 52 per cent. of those who had had it, and 9 per cent. of those who had never had it reacted positively. He concluded that the test was not diagnostic. The discrepancy between the results is probably due to the greater potency of Sauer's vaccine, and to the higher concentration of bacilli used (10,000 million in Sauer's vaccine against 2000 million per c.cm. in that used by Orgel).

I am, Sir, yours faithfully,

B. MCARDLE.

NEUROSIS AND UNEMPLOYMENT

To the Editor of THE LANCET

SIR,—In an article by Dr. Aubrey Lewis in your issue of August 10th (p. 293), on which you commented in the same issue, the results of an investigation into the case-histories of 52 men referred to a psychiatric clinic by the public assistance committee are given. Dr. Lewis concludes that their unemployment is only one of a recurring series of factors which have precipitated a breakdown in individuals already predisposed to some form of neurosis. He points out the necessity of obtaining a series of men previously stable and well adapted to test the almost universal impression that unemployment is in itself a major ætiological factor in mental illness.

The figures I have collected during the year 1934 may be of some interest in this connexion. From Jan. 1st to Dec. 31st, 1934, there were admitted to the Notts County Mental Hospital 91 male patients of whom 14 were unemployed prior to admission. All these 14 patients had at some time or other been employed and their unemployment had varied from three months to several years. Of these 14, 7 were schizophrenics of whom, apart from one case, it was impossible to form a judgment as to whether the unemployment was an ætiological factor; one had general paralysis, and one was a high-grade defective. The remaining five had manic-depressive forms of insanity and in each case there existed other factors in the history, such as the death of a father, domestic trouble, privation, sufficient to render it difficult to decide which was the precipitating factor. However, in all these five, and in one of the schizophrenics mentioned above, the unemployment was judged to be a major factor. In all six cases there was no history of previous breakdown or neurosis with the exception of the one schizophrenic who was a nystagmus subject. An inquiry into their previous personality yielded nothing definite. The five manic-depressive patients were able to go home; they had proved themselves cheerful and willing workers and in no way gave the impression of being chronic social problems.

The county population from which these admissions were drawn is 448,500.

I am, Sir, yours faithfully,

Radcliffe-on-Trent, August 14th. H. A. PALMER.

PROCTALGIA FUGAX

To the Editor of THE LANCET

SIR,—A few years ago a distinguished surgeon from the North of England invited opinions in one of the medical journals upon a condition which appears to be identical with "proctalgia fugax." I have been expecting some reference to the former discussion in the correspondence to which you have recently opened your columns; for judging by the number of communications on that occasion, the condition is by no means uncommon. I myself have had the opportunity to observe the symptomatology in a near relative for over twenty years. I had never been able to discover any references in the literature which had any bearing upon what was so elusive a peculiarity and at one time I wrote to seek assistance from continental confrères, to receive the superfluous reminder that rectal crises must not be forgotten, a reminder which has, I see, been echoed by one of your correspondents in a recent issue.

But during the last few years I have been surprised to gleam from conversations with colleagues that many of them were themselves sufferers in greater or less degree; and I notice that Dr. John Ryle has made the same discovery. The symptoms have not been universal but they have many features in common, and include the majority of those displayed by my relative who has had perhaps a hundred attacks during the period of my observation. It appears that the complaint, although not unknown in females, is very much commoner in males, and that attacks generally occur in the early hours of the morning. The sufferer is awakened by a sensation of discomfort in the rectum, which generally develops into pain extending throughout the perineum and compelling him to rise and seek relief.

The degree of pain is very variable. In its most severe form it is described as an agonising cramp which persists for a quarter of an hour but rarely longer, and gradually subsides. With the resulting relief the sufferer speedily falls asleep. Any accompanying symptoms of sweating, vomiting, collapse, or fainting would appear to be the direct result of pain rather than of any other features of a "syndrome."

The methods described to procure relief by different sufferers have been: attempt to defæcate—occasionally a small motion is passed, a hot bath, an enema, inflation of the rectum with air from a syringe, the insertion of various suppositories, all of which clearly aim at relaxation of sphincteric spasm. One physician admitted that he had on occasion been driven to a hypodermic injection of morphia. Mr. Lockhart Mummery has informed me that he was quite familiar with the complaint. He regarded it as a tic, and added that he had often found hypersensitiveness of the sacral plexus in such subjects on digital examination of the rectum—this was not present in my relative's case—and that injection of the plexus with absolute alcohol was often useful. He was further of the opinion that there must be some local occurrence—e.g., the presence of a foreign body—to activate the process.

Dr. Ryle regards fatigue as an exciting factor. At one time I thought this a likely explanation as attacks in my relative occurred in the night following strenuous exercise. But such a relationship was by no means constant nor in fact was any convincing explanation forthcoming. If however we accept Dr. Ryle's description of it as a visceral neurosis, it is easy to understand how a little extra fatigue, mental or physical, would be quite sufficient in the case of what after all must be a highly predisposed subject. I am, Sir, yours faithfully,

ADOLPHE ABRAHAMS.

Brook-street, W., August 16th.

To the Editor of THE LANCET

SIR,—I was much interested in Dr. Hess Thaysen's article about this strange "proctalgia fugax," because it is the first description I have seen of this most distressing rectal pain. For four years I have had under my care a woman of about 40 with this kind of pain. Sudden and very sharp, it usually awakens her at night, becomes more and more severe and, from a precise point 12 cm. above the anus, radiates into the entire pelvic region, giving an impression of intense cramp in the uterus. The attack lasts a few minutes and then disappears, leaving the patient very tired. This patient has been operated on many times; she has had colitis and hæmorrhoids, and has suffered different kinds of pelvic and rectal pains; and she is sure that this neuralgia is entirely independent of the state of her colon and hæmorrhoids. The attacks always occur just before or after the monthly periods. They seem to be more frequent when she lies on a hard bed; the first attack came on when she had been some weeks in a clinic where her bed was too hard.

Sometimes the patient feels the attack is coming and she can then control it with a suppository of Cibalgine. After examination by a neurologist and by a gynæcologist who could find no cause for the pain, she had a few sittings of short-wave diathermy of the pelvi-rectal region; this was six months ago and she has had only a single mild attack since.

I am, Sir, yours faithfully,

Lausanne, Switzerland, August 15th. R. M. TECON.

"LIFE WITHOUT BREATHING"

To the Editor of THE LANCET

SIR,—The annotation under this heading in your last issue reminds me of some, as yet unpublished, experiments I performed at the Lister Institute in 1922. Oxygen injected into the veins at ordinary atmospheric pressure generally does more harm than good, by filling the right heart with froth. I therefore made an apparatus by means of which I could deliver oxygen at a pressure between 200 and 250 mm. Hg, at any required rate. Using a small branch of the femoral artery as a cannula, I injected an average of 10 c.cm. per minute into the femoral artery of an anæsthetised dog. The idea was to use the capillaries of the leg as a lung, and for splitting up the oxygen into very fine bubbles. No apparent harm resulted to the dog, and it continued to make regular respiratory movements in spite of the fact that O_2 was entirely withheld. After two hours of life under these conditions the dog was killed.

This experiment was repeated, both in dogs and cats, but the result was never again so entirely successful, twenty minutes being the limit of survival when breathing N_2 only. Possibly a combination of Singh's methods and mine might be the best means of artificial aeration of the blood.

I am, Sir, yours faithfully,

Whitechapel, E., August 16th. THOMAS LUMSDEN.

THROMBO-ANGIITIS OBLITERANS

To the Editor of THE LANCET

SIR,—The case of thrombo-angiitis obliterans following gassing recorded by Dr. McDougall and Dr. Crawford in your last issue was of special interest to me because the notes of the case were submitted to me by a solicitor accompanied by a request to support the claim for a pension. Having seen some number of cases of Buerger's disease in none of which a history of gassing was obtained, and having had under my care many patients who gave histories of gassing none of whom had developed thrombo-angiitis obliterans, and also in the absence of any cases recorded, I replied that I regretted that I was unable to comply with the request. Dr. McDougall and Dr. Crawford are very persuasive in their able paper; but is it safe to conclude from a single case that some preceding condition is an ætiological factor? It would be of interest to learn from those who have seen many cases of Buerger's disease from what percentage a history of gassing can be extracted, and from those who have seen many cases of gassing in what percentage thrombo-angiitis obliterans has developed.

I am, Sir, yours faithfully,

Portland-place, W., August 20th. O. LEYTON.

PANEL AND CONTRACT PRACTICE

Wanted a Definition of Assistant

THE London insurance committee is still in difficulty how to define an assistant in those cases where a practitioner is permitted, by virtue of his having obtained the committee's consent to the employment of an assistant, to accept a greater number of insured persons than is allowed to a practitioner working single-handed.

Dr. A. had employed an assistant, Dr. B., for a number of years, and on Dr. B.'s death Dr. C. was appointed in his stead. The committee found, however, that Dr. C.'s name was already included in their medical list in respect of a practice situate near the boundary of the county, some six miles distant as the crow flies, where he had a few insured persons included in his London list and others in his list for the adjacent area. Inquiries being sent to Dr. C., it was found that he was absent from the practice owing to illness. He was asked as to the arrangements made for his own practice during his absence and he replied that he desired to transfer the insured persons included in his own list to that of his principal, Dr. A. The question then arose whether the amount of assistance which was being given to Dr. A. was sufficient, having regard to the somewhat large excess of acceptances over the limit applying to a practitioner working single-handed. Clearly while Dr. C. had had a responsibility for his own practice he had not been able to give full-time assistance to Dr. A. nor had Dr. A. had a first call upon his services. In March, 1930, a report was submitted by the medical service subcommittee which contained the following statement:—

> There nowhere appears either in the terms of service or the allocation scheme any indication as to the extent to which an assistant should be employed by a practitioner. We are aware, however, that the committee have laid it down that if a practitioner is required to employ an assistant by virtue of the number of insured persons on his list, such assistant should be a whole-time assistant. If the term "whole-time" is to be taken as connoting that an assistant must be actually in the practice for the whole of his time, it is clear that this will operate unequally, as between the case of a practitioner who exceeds the maximum number by the full quota—namely, 1500—and the case of a practitioner whose list is in excess by only a small number. It appears to us that the extent to which a practitioner employs an assistant is primarily a matter for determination by the practitioner, but he must have reasonable regard to the circumstances of the practice. The matter is not, in our view, free from difficulty, but we consider, in the absence from the regulations of any precise definition, that the spirit of the requirement is met if a practitioner has a bona-fide arrangement with a salaried assistant whereby he has the first call on the services of that assistant. Any such arrangement should, of course, be such as to secure continuity in the employment of an assistant, and an assistant should not be in a position to discontinue his service with the practitioner by whom he is employed without proper notice. It follows as a corollary to the foregoing that, if it were established to our satisfaction in any case that a practitioner had not taken all the steps reasonably open to him to secure continuity of employment of an assistant and had not bona fide employed an assistant continuously in his practice, we should have no alternative but to regard it as a failure on his part to observe the conditions governing the con-

sent to the employment of an assistant and to recommend that a portion of the extra remuneration which he secures by virtue of the employment of an assistant should be withheld from him, the amount withheld being dependent upon a consideration of the whole of the circumstances and not merely upon an arithmetical calculation.

The subcommittee referred also to a report submitted in July, 1933, wherein it expressed the view that the concession enabling a practitioner to accept an increased number of insured persons owing to his employing an assistant presumed that the two practitioners would be working concurrently. The insurance committee decided that the whole question of the definition of an assistant where a practitioner is required to employ an assistant required examination, the circumstances of the case above cited being a demonstration of the necessity. It is accordingly consulting with the local medical and panel committee with a view to the withdrawal of consent from Dr. A. to employ an assistant. This will enable the whole situation to be examined and it is to be hoped that a proper definition of what constitutes an assistant may be forthcoming.

An Appeal

Except in certain prescribed circumstances an insurance practitioner is not permitted to demand or accept any fee or other remuneration in respect of treatment which he is required to give under his terms of service, and further he may not charge an insured person for specialist treatment unless he proves not only that the service is of a specialist nature but also that he is properly qualified to give the treatment. The wording of Clause 10 seems clear enough and yet it not infrequently happens that a doctor, having charged as he thinks properly, is called upon to defend his action. For instance, a doctor, who had been treating an insured person for chilblains, on six occasions applied ultra-violet radiation for which he received 12*s*. The condition of the patient did not yield to the treatment, and the doctor then advised her to apply for further treatment at a hospital in London. He was invited by the insurance committee to complete form G.P.45 in order that the propriety of his charge might be tested, but he replied that it had been made clear to the patient that the "apparatus and treatment for her condition" was the affair of a certain Mr. X., assistant radiologist to the Y Hospital. As the patient could not attend during the hours when Mr. X. was available he applied the treatment on Mr. X.'s behalf, the fees being those he would have charged himself. The doctor accordingly expressed himself as unable to complete form G.P.45. It seems that the doctor and Mr. X. had entered into an agreement some sixteen months earlier whereby Mr. X. had the use of the doctor's professional room two hours every afternoon for the purpose of giving radiation treatment. The doctor having himself applied the treatment in this case retained the fees as a set-off against the rent payable by Mr. X. Unfortunately Mr. X. was not all that he should be, for in connexion with other proceedings it was reported that he had claimed to be a doctor, had professed to have had experience as a radiologist in the army, and to have had radiology experience at the hospital, all of which had been proved to be false. The medical service subcommittee took a serious light of the transaction. The doctor's knowledge of the possibility of ray treatment being regarded as forming part of his terms of service (he admitted having had this possibility brought to his notice some time ago in another area) led to the inference that he had endeavoured to divest himself of his responsibilities as an insurance doctor on the ground that the apparatus used by him for the treatment of his patient belonged to some other person. The committee proposed a refund of the 12*s*. to the insured person and recommended the Minister to deduct £10 from his remuneration. The committee decided also to ask the Minister to lay before the General Medical Council the facts of the doctor's association with an unqualified person. It is understood that the doctor has appealed against the committee's decision.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. L. Warren, O.B.E., to *St. Angelo* for R. N. Hospl., Malta, and promoted to rank of Surg. Rear-Admiral.

Surg. Rear-Admiral H. R. H. Denny, C.B., placed on the Retd. List at own request.

Surg. Comdr. W. G. Thwaytes placed on the Retd. List at own request, with rank of Surg. Capt.

Surg. Lt.-Comdr. V. G. Horan to *President* for course.

Surg. Lt.-Comdr. J. L. Malone to *Delhi* (on transfer of flag).

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Comdr. H. Parry-Price and Surg. Lt.-Comdr. H. M. Petty to *Victory* for R.N. Hospl., Haslar.

Surg. Lts. D. R. Hughes and W. H. C. Watson to *Neptune* and A. Elliott to *Rodney*.

Surg. Lt. E. R. G. Passe, promoted to Surg. Lt.-Comdr.

ARMY MEDICAL SERVICES

The War Office announces that Col. H. H. A. Emerson, commandant and chief instructor at the Army School of Hygiene, Aldershot, has been selected for appointment as director of hygiene at the War Office with effect from Oct. 6th, 1935, in succession to Maj.-Gen. P. H. Henderson, C.B., honorary physician to the King, who will vacate the appointment on completion of four years' service as a major-general. Lt-Col. A. C. Hammond-Searle, assistant director of hygiene at the War Office, has been selected to succeed Col. Emerson as commandant at the Army School. His successor at the War Office will be Lt.-Col. D. T. Richardson, R.A.M.C.

ROYAL ARMY MEDICAL CORPS

Short Serv. Commissions.—Lt. H. V. D'A. Iles to be Capt.

TERRITORIAL ARMY

Lt.-Col. and Bt.-Col. E. A. C. Fazan, M.C., T.D., from R.A.M.C., Gen. List, to be Col. June 29th, 1935, with seniority Feb. 16th, 1934. (Substituted for the notification in the *Gazette* of June 28th, 1935, *vide* THE LANCET, July 6th, p. 44).

Lt-Col. J. A. Stenhouse, T.D., to be Bt.-Col.

Capt. H. Watson resigns his commn.

The King has conferred the Territorial Decoration upon the undermentioned Officer under the terms of the Royal Warrant dated Oct. 13th, 1920: Lt.-Col. Edward Hillis Marshall, D.S.O. (ret.).

Maj. I. H. Lloyd-Williams, M.C., from T. A. Res. of Off., to be Maj.

Lts. E. H. Jaques and D. Campbell to be Capts.

Lt. Walter Heard, late M.G.C., to be Lt.

ROYAL AIR FORCE

Wing Comdrs. J. T. T. Forbes to Central Flying School, Wittering, for duty as Medical Officer, and W. E. Hodgins to Home Aircraft Depot, Henlow, for duty as Medical Officer.

Squadron Leader W. E. Barnes to Princess Mary's R.A.F. Hospital, Halton, for duty as Medical Officer.

Flight Lts. N. I. Smith to No. 2 Flying Training School, Digby, and V. H. Tompkins to No. 20 (Army Coöperation) Squadron, Peshawar, India.

INDIAN MEDICAL SERVICE

Capt. A. Tait to be Maj. (provl.).

Lt.-Col. G. Holroyd has retired.

MEDICAL NEWS

University of Dublin

A post-graduate course will be held at Trinity College from Sept. 16th to Oct. 5th. It will consist of clinical instruction, formal lectures, and laboratory work. Further particulars may be had from the dean of the faculty of physic, Trinity College, Dublin.

Victor Horsley Lecture

The fifth Victor Horsley memorial lecture will be delivered by Sir Walter Langdon-Brown, regius professor of physic in the University of Cambridge, in the lecture theatre of University College Hospital medical school, on Tuesday, Nov. 19th, at 5 P.M. The title is the Integration of the Endocrine System and the chair will be taken by Sir Gowland Hopkins, O.M.

Medical Society of London

The programme for the first half of the 163rd session of this society opens with the annual general meeting at 8 P.M. on Monday, Oct. 21st, after which, at 8.30 P.M., Prof. G. E. Gask will give his presidential address, entitled Changing Surgery. Dates and subjects for the Monday evening discussions are as follows: Oct. 28th, electrical injuries (to be introduced by Dr. Macdonald Critchley and Dr. John Aydon); Nov. 25th, the use and abuse of insulin (Dr. R. D. Lawrence and Dr. George Graham); and Dec. 9th, the care and treatment of difficult children (Dr. Reginald Miller and Dr. William Moodie). On Nov. 11th there will be a clinical meeting. The Lettsomian lectures for 1936 will be given by Dr. P. H. Manson-Bahr on Feb. 17th, 26th, and March 2nd, his subject being the differential diagnosis of diseases of the colon (dysentery and colitis) and their complications, with special reference to treatment. Sir James Walton will deliver the annual oration. The address of the society is 11, Chandos-street, W.1.

Tomarkin Foundation

The seventh international medical post-graduate congress of this foundation will be held in two sections this year. From Sept. 12th–19th the congress will meet in Brussels, where the first session in which the International Union Against Cancer is coöperating is to be in honour of Pierre and Marie Curie and will deal with cancer. Mr. and Mme Joliot-Curie are to be among the speakers. Discussions on tropical, subtropical, and infectious diseases will be held under the presidency of Sir Aldo Castellani, and other speakers will include Dr. W. Levinthal and Prof. C. Levaditi. At another meeting a delegation of Italian neurologists will give a symposium on recent advances in the treatment of post-encephalitic parkinsonism. From Sept. 20th to Oct. 2nd the congress will meet at Spa where diseases of the cardiovascular system will be discussed; the speakers will include Sir Crisp English, Sir Harold Gillies, and Prof. J. Plesch. At a session on diseases of the blood Prof. U. Friedemann will read a paper on the blood-brain barrier. After the congress a visit to the principal Italian universities has been organised. Further information may be had from the secretary of the foundation, 97, Rue aux Laines, Brussels.

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Mental Hospital.—Asst. Physician. £300.

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

All Saints' Hospital for Genito-Urinary Diseases, Austral-street, S.E.—Res. H.S. At rate of £100–£150.

Birkenhead Municipal Hospital.—Sen. Res. M.O. £350. Also Res. M.O. £300.

Blackburn County Borough.—Asst. M.O.H. £600.

Blackburn Royal Infirmary.—H.S. £175.

Board of Control, Rampton State Institution for Mental Defectives, nr. Retford.—Deputy Med. Supt. £847. M.O. £515.

Bristol, City and County of.—Asst. M.O.H. £500.

British Postgraduate Medical School, Ducane-road, Shepherd's Bush, W.—Cas. O.'s. At rate of £150. Also H.P.'s and H.S.'s.

Burton-on-Trent General Infirmary.—H.S. £150.

Cardiff Royal Infirmary.—H.P.'s and H.S.'s. At rate of £50. Also H.S. to Ear, Nose, and Throat Dept. At rate of £100.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. £120 and £100 respectively.

Chester Royal Infirmary.—H.S. for Special Depts. £150.

Chichester, West Sussex County Mental Hospital.—Third Asst. M.O. £350.

Coventry and [illegible] Res. Surg. O. £200.

Denbighshire [illegible] [illegible]I.O.H., &c. £1100.

Dewsbury and [illegible]—Sen. H.S. £200.

Doncaster Ro[illegible] [illegible]ye and Ear, Nose and Throat Depts. £175.

Doncaster Royal Infirmary and Dispensary.—Sen. Res. £250. Also Res. Anæsthetist. At rate of £175.

Dreadnought Hospital, Greenwich, S.E.—Receiving Room Officer and H.P. At rate of £200 and £110 respectively. Also H.S. At rate of £110.

Dudley, Guest Hospital.—H.S. and Second H.S. £200 and £170 respectively.

Dumfries and Galloway Royal Infirmary.—Supt. £500.

East Ham Memorial Hospital.—Pathologist. £300.

Epsom County Hospital.—Res. Asst. M.O. At rate of £250.

[illegible] *Borough.*—Jun. Asst. Maternity and [illegible] £500.

[illegible] *Ducane-road, W.*—Asst. Radiologist. [illegible]

Harrogate and District General Hospital.—H.P. and Cas. O. Also H.S. Each at rate of £150.

Herefordshire General Hospital.—H.S. and Cas. O. £100. Also H.P. £100.

Huddersfield, Mill Hill Isolation Hospital.—Res. M.O. £350.

Huddersfield, St. Luke's Hospital.—Res. M.O. £200.

Hull, Anlaby-road Institution.—Asst. M.O. £350.

Kingston and District Hospital.—Visiting Physician. £300. Also Visiting Aural S., Orthopædic S., and Neurologist.

L.C.C. Public Health Dept.—Social Workers for Special Hospitals. Each £235.

Leamington Spa, Warneford General Hospital.—Res. H.S. to Cas., &c., Dept. At rate of £150.

Leicester City Mental Hospital, Humberstone.—Third Asst. Res. M.O. £350.

Leicester County Sanatorium and Isolation Hospital, Markfield.—Res. M.O. £400.

Leicester Royal Infirmary.—H.S.'s, Cas. O., H.P.'s, Jun. Res. Anæsthetist. Each at rate of £125. Also Jun. Cas. O. At rate of £100.

Liverpool Heart Hospital.—H.P. At rate of £100.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Second Asst. to Med. Supt. £200.

Liverpool Women's Hospital, Catharine-street.—H.S. At rate of £100

Macclesfield General Infirmary.—Second H.S. £150.

Manchester, Christie Hospital and Holt Radium Institute.—Asst. Radium Registrar. £400–£500.

Manchester, Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s. Each at rate of £150.

Marie Curie Hospital, 2, Fitzjohn's-avenue, N.W.—Pathologist.

Middlesbrough, North Riding Infirmary.—Third H.S. £125.

Miller General Hospital, Greenwich-road, S.E.—Two Cas. O.'s. Also Out-patient Officer. Each at rate of £150. Also H.P. and H.S. Each at rate of £100.

Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. or H.S. At rate of £100.

Northern Ireland Ministry of Labour.—M.O. £738 12*s.*

Northumberland County.—Sen. Tuber. O. £800.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Norwich, Norfolk and Norwich Hospital.—H.S. to Surg. Out-patient Dept. £200.

Nottingham General Hospital.—H.S. for Ear, Nose, and Throat Dept. Also Cas. O. Each at rate of £150.

Plymouth, Prince of Wales's. Hospital, Lockyer-street.—H.S. At rate of £150.

Preston, Biddulph Grange Orthopædic Hospital.—Jun. H.S. At rate of £150.

Preston and County of Lancaster Royal Infirmary.—H.P. At rate of £150.

Prince of Wales's General Hospital, N.—Hon. Surg. Reg. to Ear, Nose, and Throat Dept. £100. Also Jun. H.P. and two Jun. H.S.'s. Each at rate of £90.

Richmond, Surrey, Royal Hospital.—Jun. H.S. At rate of £100.

Rotherham Hospital.—Cas. H.S. £150.

Royal Eye Hospital, St. George's-circus, Southwark, S.E.—H.S. and Asst. H.S. At rate of £150 and £100 respectively.

Royal National Orthopædic Hospital, Gt. Portland-street, W.—Two H.S.'s (one for Country Branch). Each at rate of £150.

St. Helens County Borough.—Asst. M.O.H. £500.

St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C.—H.S. At rate of £75.

Sheffield Royal Infirmary.—Second Asst. Cas. O. At rate of £80.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.S. At rate of £150.

Surrey County Council.—Asst. M.O. £600.

Tilbury Hospital, Essex.—H.S. At rate of £140.

Weir Hospital, Grove-road, Balham, S.W.—Sen. Res. M.O. £200. Jun. Res. M.O. £150.

West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each at rate of £100.

Windsor, King Edward VII. Hospital.—H.S. At rate of £100.

[illegible] *Royal Hospital.*—H.S. for Fracture and [illegible] At rate of £100.

[illegible] *War Memorial Hospital, Shooter's Hill, S.E.*—Res. M.O. £175.

Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £150.

York Dispensary.—Res. M.O. £175.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Ruthin, Denbigh.

NOTES, COMMENTS, AND ABSTRACTS

WILLIAM STARK, M.D.

AN EIGHTEENTH CENTURY EXPERIMENT IN NUTRITION

BY J. C. DRUMMOND, D.Sc.
PROFESSOR OF BIOCHEMISTRY, UNIVERSITY OF LONDON; AND
ANNE WILBRAHAM
(From the Department of Biochemistry, University College, London)

AT 4 P.M. on the afternoon of Friday, Feb. 23rd 1770, a rather remarkable young medical man William Stark, died in London. For some time he had been experimenting on himself with great perseverance with the object of studying the effect of different types of foods on health. The pages of his meticulously recorded journal show all too clearly why he came to so untimely an end. His work is curiously little known. Indeed, the only reference to it which we have found is in Graham Lusk's short and scholarly "History of Metabolism," itself a work known to comparatively few.

Sources of Information

The manuscript notes of Stark's experiments, together with a number of highly interesting and carefully compiled anatomical and clinical observations, passed after his death into the hands of the Hon. Thomas Fitzmaurice, who appears to have acted in some way as the young man's patron. Fitzmaurice obviously thought the records worthy of publication, for he sought an editor. Dr. James Carmichael Smyth, of the Middlesex Hospital, physician extraordinary to King George III., accepted the task and the volume appeared in 1788. Smyth's preface gives a brief concise biography of young Stark, to which we are now able to add a few details. Generally speaking, however, our search for information about his life has proved disappointing.

The first record of him is in the Matriculation Album of Glasgow University where he matriculated in 1753. He is there described as "Gulielmus Stark filius natu maximus Thomae Stark mercatoris in Urbe Manchester." This record also states that he was born in Birmingham in July, 1740, but we have not been successful in tracing a baptismal or other entry in that city. One imagines that at Glasgow he came under the influence of that great teacher William Cullen, for after taking his M.A. there in 1758 he moved to Edinburgh to study medicine. Cullen, appointed to the Chair of Chemistry at Edinburgh in 1755, had begun his famous series of clinical lectures at the infirmary there in 1757. A few years earlier Black, another of Cullen's students in Glasgow, had also moved to Edinburgh to study medicine, and subsequently published his inaugural dissertation "De humore Acido a Cibis Orto, et Magnesia Alba," which marks the birth of modern chemistry.

His Move to London

Stark did not take a degree at Edinburgh. He decided to move to London and to work with John Hunter so that he could continue the anatomical studies in which his interest had been so deeply aroused by Monroe. He came south in 1765. Probably even at that time he hoped to be appointed to the staff of St. George's Hospital, for in the Minute Book of the Hospital we read that on March 19th, 1766, the clerk paid in "a subscription of five guineas from William Stark, a new subscriber, to Lady Day, 1767." Mr. R. R. James, F.R.C.S., an authority on the history of St. George's and its medical school, informs us that this payment probably made Stark a governor, and that at that time it was customary for those who aimed at a post on the honorary staff to become governors in order to increase their chances of success. Both Gataker and John Hunter appear to have taken this precaution.

After the first entry there is a long series of records of Stark's attendance at the weekly board meetings and general quarterly courts of the Hospital. His last attendance was apparently on Jan. 17th, 1770, a month before his death. One or two of these entries are of interest, for they tell us that he was on more than one occasion appointed to the Committee which had the task of auditing the accounts for the year and "settling the annual list and the gratuities to the servants." He was also present at the Special General Court held on Dec. 9th, 1768, when John Hunter was elected surgeon. A month later came the opportunity for which he had doubtless been waiting. A physician, Dr. Jebb, retired from the staff and his successor was to be appointed. The Quarterly General Court met on Jan. 6th, 1769. The name of Dr. Richard Wright was proposed by Sir Clifton Wintringham. Stark was present and his name was brought forward by John Drummond. The committee proceeded to take a vote, "the ballot being kept open until 2 o'clock in the afternoon." Wright was elected by 111 votes to 39.

Almost a year later another chance occurred. Dr. Wilkinson Blanshard died and the Yearly General Court was asked to select a physician in his place. At this time Stark was occupied with his experiments on diet and was, as a result, rapidly undermining his health. In his Journal for January, 1770, we read: "Having since the 5th been engaged in a canvas for St. George's Hospital, I have been rather irregular in respect to diet, living rather more freely, and drinking more wine than usual." On the 19th his hopes were failing, for he wrote: "I was still low-spirited and dull, but this was, possibly, in part, owing to my having small hopes of success at St. George's Hospital." On Feb. 2nd the court elected Dr. Petit to the vacancy.

Of Stark's three years of life in London we know practically nothing. His journal gives us fleeting glimpses which seem to show a quiet, retiring and rather serious-minded individual. Almost certainly he was a bachelor. In describing his dietetic experiments he speaks first of getting his meals in from an eating house and later of cooking them himself in a double saucepan which he devised for the purpose. His name does not appear in the London Register of Marriages for the years in question, and, moreover, there is no suggestion in the pages of his journal that he had a wife. His circle of friends is of particular interest, because of the influence which some of them appear to have had on his work. When he was first in London his interests were those which clearly had been aroused during student days by Cullen and Monroe—namely, chemistry and morbid anatomy. Of the former Smyth remarks:

> "Whilst attending the hospital, he was also employed in making experiments on the blood and other animal fluids; and likewise in a course of experiments in chemical pharmacy, which are still extant; and give the strongest evidence of his accuracy and diligence; but whether they are of importance enough to be presented to the public, I have not yet had leisure to ascertain."

Contact with Sir John Pringle

So far as we know these notes have not appeared in print and the whereabouts of this MS., as well as of the main part of Stark's published work, if indeed they have been preserved, is not known. A number of his studies in morbid anatomy are fully set out in the first section of Smyth's compilation. In every detail they reveal the mind of a keen, observant and well-trained investigator. Whilst in London Stark met and became a friend of Sir John Pringle. It may have been this contact that led him to present a thesis at Leyden, for Pringle had been educated there. At any rate Stark registered at the University on Sept. 2nd, 1766, and a little more than a fortnight later was promoted to his doctorate in medicine for a thesis entitled "Specimen Med. Inaug. septem Historias et Dissectiones Dysentericarum exhibens."

About this time another friendship was made, and there are reasons for thinking that from this arose the remarkable diversion of interests that led to the experiments on diet being planned. Benjamin Franklin was in England from 1764 to 1775, and he and Stark became acquainted. The American doctor had for long been interested in the function of foods. He held a brief for the simple life: "If thou art dull and heavy after meat it is a sign that thou hast exceeded due measure; for Meat and Drink ought to refresh the Body and make it cheerful and not to dull or oppress it." He told Stark that when a journeyman printer he had lived a fortnight on bread and water, at the rate of 10 lb. of bread per week, and found himself stout and hearty on the diet.

Stark's curiosity was aroused. He consulted his colleagues. Sir John Pringle told him of Greeks who lived wholly on currants and of a more astonishing case of an old lady of 90 whose sole sustenance was mutton fat! Hewson, then lecturer at William Hunter's school, contributed a second-hand story of sailors living solely on tobacco or sugar; the latter dying of scurvy, the former living in health. And so from his friends and colleagues he gathered an ill-assorted collection of observations—and a tall story or two—about curious diets and digestion in the human stomach.

It is clear from his introduction to the description of the experiments on diet that the main task Stark set himself was to decide by direct experiment whether very simple diets, such as Franklin had advocated, were compatible with health. He remarked naïvely:

> "I confess it will afford me singular pleasure if I can prove by experiment, that a pleasant and varied diet is equally conducive to health, with a more strict and simple one; at the same time I shall endeavour to keep my mind unbiassed in my search after truth, and if a simple diet seems the most healthy I shall not hesitate to declare it."

In planning the experiment he was in some doubt whether to make observations of the excreta, for "I have sometimes doubted whether an accurate attention to the discharges of the body be not more a matter of curiosity than of use." However, he goes on to say—and one may be forgiven the suspicion that he had an eye on the possibility of a vacancy on the hospital staff:

> "If after what I have said I shall be thought to have indulged myself with attending too accurately to the discharges of the body, it must be partly imputed to my desire to avoid the appearance of entertaining a doubt that what some of the first names in Physic have thought deserving their attention were things of little moment."

Stark's First Auto-experiment

His first experiment on himself began on June 12th, 1769.* He is described as 29 years old, 12 st. 3 lb. in weight, stoutly made but not corpulent, of a florid complexion, with red hair. It is reasonable to make the assumption in the first place that, up to the time his experiments began, he had been living on an adequate and varied diet and, secondly, that he was of sedentary habits. Dr. J. R. Robertson, of the Middlesex Hospital, has very kindly provided us with an assessment of his heat output as 78·5 calories per hour, corresponding to a basal requirement of 1880 calories daily. We may, therefore, estimate his daily requirements at 3000 to 3200 calories.

Doubtless with Benjamin Franklin's experience in mind Stark's first experiment was to study the effects of a diet of bread and water. For no less than ten weeks he lived almost exclusively on bread and water, the only change being that for a period of about a fortnight he allowed himself in addition a ration of sugar. On 20 oz. of bread daily he felt hungry and lost weight, which is not surprising when it is noted that his calorie intake was well below the estimated basal requirements. When he raised his consumption of bread to 30 oz. daily his loss of weight became smaller and he stated that he felt hearty. A further increase to 38 oz. enabled him to put on a little weight and to record that his appetite was fully satisfied and that sometimes he had more than he could eat. From this we may fairly draw the conclusion that his sedentary life actually did call for about 3000 calories a day. The relationship between body-weight and calorific intake is clearly traced in the accompanying figure, Period I.

What might be the effect of this diet over a period of ten weeks? Almost certainly his bread was "wholemeal" wheaten flour—such is the assumption we have made in calculating from his records of food eaten what were his intakes of protein, fat, and carbohydrate—so that one is able to say that the defects of the diet were (i) a paucity of fat, (ii) protein of low biological value, (iii) deficiency of fat-soluble vitamins A and D, and (iv) almost complete absence of vitamin C. From present-day knowledge of diets for adults little importance is attached to the low intake of fat, whereas the amounts of wheat proteins, even at the lowest level, were in all probability sufficient for maintenance. Nor are there grounds for any great concern at a low intake of vitamins A and D by a fully grown man over a period as short as ten weeks. The same cannot be said of the shortage of vitamin C. Stark was living dangerously on a scorbutic diet.

On August 11th, two months after the experiment began, he noticed that his gums were swollen and bled easily, and that the inside of one nostril was purple and very painful. From then onwards until Sept. 5th his journal contains frequent references to symptoms all too clearly scorbutic. A certain alleviation of the condition from time to time indicates that he was suffering from a mild chronic form of the malady, and it is rather curious that apparently he did not then recognise what was wrong.

The development of definitely scorbutic symptoms in a period as short as two months is perhaps remarkable. The records of sea voyages usually indicate that at least four months would elapse before the disorder appeared. A more appropriate comparison, however, is provided by the cases described by Holst and Fröhlich in their classic paper on scurv published in 1912. In these the characteristi lesions appeared after periods of six to seven months subsistence on bread and water. A possible explanation is that Stark had been living for some tim prior to the beginning of his experiment on a di rather low in vitamin C.

On every page of his journal one reads somethin that reveals his desire for investigation and his powers of observation. Wishing to know how long food is retained in the body he marks its passage with mustard or carraway seeds. Suspecting that the activity of the salivary glands is increased during a meal, he measures it and finds "the quantity of saliva secreted in half an hour, to be, whilst the parts were at rest, four drachms, whilst eating, five ounces four drachms."

The Rigour Relaxed

It is fortunate that the plan of Stark's experiments enables us to group them conveniently for study (see Table). During the first period (June 12th to Sept. 5th) his diet was restricted to bread, water, and sugar, apart from a small amount of olive oil for one week. By early September he had lost nearly a stone of weight, his appetite had gone, and he found himself dull and listless. Scorbutic symptoms were persisting and were indeed rather more marked, and there were also clear indications of an associated intestinal disorder. He felt justified in relaxing the rigour of his self-imposed restrictions and for a few days "lived freely on animal food, milk, and wine; when I felt myself quite recovered." The records show that he put on several pounds of weight and that the condition of the sores in his mouth rapidly improved.

---

* In the copy of Stark's works (1788) in the Library of University College, London, this date is incorrectly given as July 12th.

No. of exp. in Stark's Journal.	Date in 1769.	Food.	Period in text.	Remarks.
1–3	June 12th–Sept. 13th.	Bread & water.	1	Sugar taken in one experiment and olive oil in another.
4	Sept. 14th–Oct. 2nd.	—	2	Diet irregular; animal foods and milk taken.
5–9	Oct. 3rd–Nov. 25th.	Bread & meat.	3	Meats were roast goose, stewed or boiled beef.
10–15	Nov. 26th–Dec. 26th.	Flour & oils.	4	Diet consisted of puddings made with flour and various fats and oils.
16–22	Dec. 27th–Jan. 3rd, 1770.	Bread & lean or fat meat.	5	Alternate experiments, each of a few days, comparing value of lean meat with the fat.
23	Feb. 4th–Feb. 15th.	Bread & honey.	6	—

The next experiment (4) is of no particular interest. He took quite large amounts of milk, and, for a few days, meat, so that it constitutes something resembling a "control" period (2). He regained weight and his general condition improved.

The experiments 5–9 which Stark undertook from Oct. 2nd to Nov. 25th can conveniently be grouped together (Period 3). During most of this time he was living on bread and cooked meats, sometimes with added fat. For some time, until Oct. 28th, his intake was adequate to maintain his weight, and he noted that the condition of his gums was steadily improved. At the end of the month he remarked: "Being now in perfect health, and my gums apparently sound, I thought it a proper time to ascertain, by experiment, whether the affection of my gums, and the other complaints with which I had formerly been attacked, were occasioned by sugar, or were owing to my having persevered too long in a diet of bread and water." Accordingly for five days Stark returned to a diet of bread, sugar, and water, and recorded: "My gums were not in the least affected."

It seems that we can here trace the influence of Sir John Pringle's opinion on Stark's experiments, because at this period the distinguished military surgeon was inclined to differentiate between land and sea scurvy, and to hold the view that too much sugar in the diet might in part be responsible for the former disorder.

The remainder of this period is of little interest beyond the steady fall in weight caused by insufficient food; in one period he was living on less than 900 calories a day. It is not surprising that he often felt hungry, but it is interesting that he remarks on his good spirits.

A Month on "Puddings"

His next idea was to compare the nutritive value of flour with that of lean meat, and accordingly he lived for approximately a month (Period 4) on what must have been most unpalatable "puddings" which he himself compounded with flour, various oils, and water. Discovering what he took to be undigested fat in his fæces he reduced the amounts from 6 to 4 oz. He suffered with headaches on the higher intake of fat, but there is no reason to suspect ketosis as the anti-ketogenic margin of the diet appears to have been ample. Generally speaking he formed an unfavourable opinion of diets containing a lot of fat, although one suspects that in some cases he was unfair in his condemnation. Thus, for example the unfortunate consequences that followed the consumption of a quarter of a pound of butter on Dec. 15th were almost certainly due to the material being in some way unfit to eat.

Noticing that butter more frequently caused intestinal disturbances than did oil or suet, he made an interesting comparison between the fresh butter itself and the oil separated from it. The former caused colic and diarrhœa, the latter did not. One

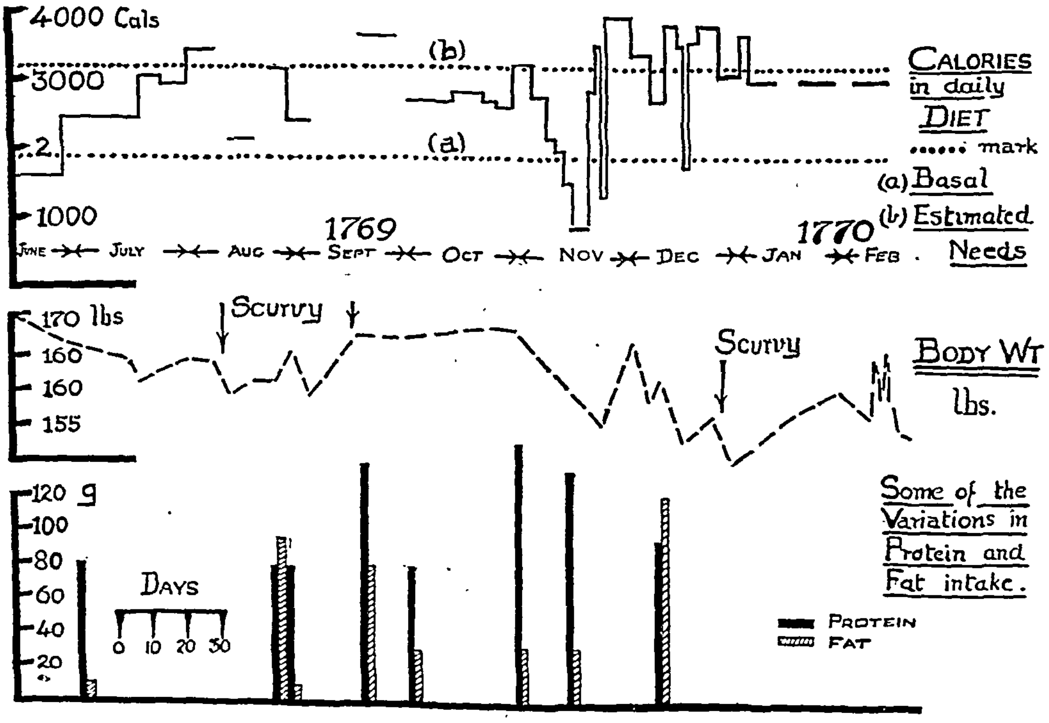

Chart showing the sequence of Stark's experiments on himself.

wonders what a bacterial examination of London milks and creams of those days would have revealed. During a good part of the time he had been living on the "flour-fat" puddings and he lacked the vigour and sense of fitness that he felt when feeding mainly on bread and meat diets. The fluctuations in his weight reflect sharply his food intake.

About this time—actually on Dec. 26th—he again noted that his gums were purple and rather swollen. The obvious scorbutic symptoms had been absent since late September when he had lived for a time on meat, milk, and other foods. If we take Oct. 2nd as the date at which unknowingly he again imposed scorbutic diets on himself—the gums apparently were normal on Oct. 14th—we find that the second onset of scurvy appeared after a period of rather less than three months.

On the evening of Dec. 26th he ate half a pint of black currants and resolved in view of the appearance of his skin and gums to change for a time his plan of living. The currants and the diet of bread and meat to which he turned seem very slightly to have improved his condition although for the next three weeks there is still frequent mention of swollen, bleeding, and septic gums. Certainly the currants did not provide a spectacular cure such as Curran (Dub. Jour. Med. Sci., 1847, vii., 83) claims to have seen following a single helping of rhubarb tart.

One observation which he made is, however, of very great interest. "Is it not probable then, that animal oils, though they nourish and increase the weight of the body, are not of themselves sufficient to prevent a morbid alteration from taking place in the blood and fluids? Whilst, on the other hand, the lean of meat, though less nutritious, is of more efficacy in preserving the fluids of the body in a sound state?" It is, of course, recognised to-day that lean meat, even after light cooking, may have a small but significant antiscorbutic value.

With the New Year he turned again to the question which several times had aroused his interest. Which was really the more nutritious, the fat or the lean of meat? He planned to live for several days first on the fat separated from the stewed meat and then for another short period on the residual meat itself. The records of the former trial are shown in Experiments 18, 19, and 21, and the corresponding "meat" experiments are 17, 20, and 22. Throughout this experiment his calorie intake was about adequate, and he slowly regained some weight in spite of digestive disturbances—which he was inclined to attribute to rancidity—when taking a lot of fat. Again he was inclined to feel dull and depressed on the high-fat diets.

A Fatal Change of Plan

And now occurred a change of plans which probably cost him his life. Originally he had intended to follow the experiments on the relative values of the fat and lean of meat by an investigation into the effect of greens and fresh fruit. Had he done so his chronic scurvy would have disappeared and his health might have so greatly improved as to enable him to withstand the intestinal infection which he appears to have contracted about this time. He does not say why he changed his mind, but the fact remains that he turned to study the food value of honey pudding and Cheshire cheese.

The intestinal disorder became progressively worse and the scorbutic symptoms more pronounced. From Feb. 14th his journal shows that his condition was becoming rapidly more serious, and after the 18th the entries cease. Even on that day, desperately ill as he undoubtedly was, he had not lost his interest in the experiment and almost the last words he wrote were: "Suspecting that my present complaints might possibly arise, in part, from the cheese, I this day omitted it."

His colleague Hewson was called in the same day to bleed him and attended him until his death on Friday, the 23rd. Attached to the published account of Stark's experiments is one account of his illness and death written by Hewson and another believed to have been recorded at the time by Sir John Pringle. There is also an account of the findings at the post-mortem examination which was carried out the following Sunday by Hunter, assisted by Hewson.[2] Stark's death was registered at St. George's, Hanover-square, but no grave or memorial has been traced.

Did Stark Realise He Had Scurvy?

To the student of nutrition the chief interest of Stark's extraordinary series of experiments must be the light they throw on human scurvy. The first symptoms were noted after he had been living for just over two months on what we recognise to-day to have been a thoroughly bad scorbutic diet. As we have remarked before, this relatively early appearance suggests that for some considerable time before his experiments began his diet had been deficient in ascorbic acid. To some extent this view is supported by what we know of the foods he ate when he tried to improve his condition by relaxing his regimen somewhat. Milk, meat, and wine might be taken but fruit and vegetables are but rarely mentioned. It is not surprising, therefore, to find that after a period on milk and meat, during which the visible lesions had cleared up, the disease was still latent. It broke out again after another three months or so on a variety of diets all showing the defect of negligible vitamin-C content.

Did Stark realise he had scurvy or not? It is hard to say. Probably at first he did not, but later in his journal there are indications that he suspected his condition was scorbutic. Worried about his gums and skin he consulted Sir John Pringle, who had considerable experience of the disease and received the advice—not uncommon in those days—to omit salt from his diet. This he did but without benefit.

Pringle may or may not have known of Bachstrom's "Causam veram et primariam Scorbuti nullam aliam esse, quam abstinentiam diuturniorem a quocunque genere recentium vegetabilium" (1734), but he must have been fully aware of the views expressed by Lind, of whose classic treatise on the scurvy three editions had then appeared. It is reasonably certain, therefore, that at this date Pringle was not much influenced by Lind's work, and that he retained the older views that too much salt and sometimes an excess of sugar were the important dietary factors in the causation of scurvy. A few years later we find him coming round to the newer theories, for in 1776 he communicated to the Royal Society a memorandum on "Late Improvements for Preserving the Health of Mariners," in which Captain Cook's observations on the antiscorbutic value of infusions of vegetables, sweetwort, and small beer were presented with obvious sympathy. The conversion came too late to save Stark.

We wish to acknowledge valuable assistance in the search for details of Stark's life from Mr. R. R. James, F.R.C.S.; Mr. R. Brough, registrar of the University of Glasgow; Dr. J. D. Comrie, lecturer in the history of medicine at the University of Edinburgh; and Mr. J. M. Churchfield, secretary of St. George's Hospital London.

---

[2] We are hoping that the other part of Stark's work, his anatomical and clinical studies, will attract the attention of someone interested in the history of medicine and qualified to express an opinion of their value. Perhaps he will also offer a diagnosis of Stark's fatal illness.

"THE AMBLYOPIA READER," by Dr. Margaret Dobson, mentioned in a leading article last week, is to be published by Oxford University Press.

MATERNITY HOSPITAL FOR HARROW.—Subject to the approval of the Minister of Health, the Harrow and Wembley urban district councils are jointly to provide a maternity hospital with 70 beds at an estimated cost not exceeding £56,000.

A NEW LINER

THE Orient liner *Orion*, which was launched at Barrow last December by the Duke of Gloucester pressing a button at Brisbane, began her first voyage last week by taking a party of guests from Tilbury to Southampton. The vessel carries 486 first-class passengers and 653 tourist-class passengers on eight decks, including the promenades, and although the wealthy traveller can still command extra elbow room there is no essential amenity on the vessel which is not open to every traveller. The C deck has been extended right to the stern, giving the tourist section a fine expanse of open games deck with its own built-in open-air swimming-bath and dressing-rooms; the tourist deck below this contains the widest expanse of promenade on the whole ship, and a children's nursery complete with hostess and stewardess, with its own lavatory, and arranged so that even in port when cargo is being worked the children may play in the open air without straying into trouble. This levelling up of accommodation which extends also to the crew's quarters is the most striking feature of the new liner. On the first-class side there are no inside cabins and all the cabins on C deck have sash windows and many on D deck have sash windows replacing the old port-hole. This is a tremendous asset for the large proportion of the voyage which is spent in tropical seas, but when windows must be closed the air-conditioning plant provides cool and if necessary dry air to every part of the boat. It is claimed that the conditioning plant is the first complete installation of its kind on a British ship and that by its means comfortable internal conditions can be maintained with the outside temperature varying from 100° to 15° F., and the relative humidity from 100 to 40 per cent. Thus the vessel contains all the elements of comfort and hygiene for a long voyage that can be desired by every kind of traveller, but there is nothing of ostentation and little suggestion of luxury, mainly because the effect does not depend on isolated pieces of decoration but on a uniform scheme pervading the whole; for an architect, Mr. Brian O'Rorke, was made responsible for the interior decoration throughout and was given control over the designers of special items and the firms carrying out the decorative construction. There can be no boat on the water in which the design is so restful and harmonious within and without, or in which there is no dark corner to be found. Nor is there any apparent sacrifice to speed. When really steaming at 21 sea-miles an hour the vessel's single funnel and mast with scarcely any rake create an illusion of gentle indolence, confirmed by the entire absence of engine vibration. The medical arrangements are unobtrusive but sufficient. There are two experienced surgeons on board. The hospital is a self-contained deckhouse, divided into four sections so that infectious cases may be effectively isolated; a decorative pestle and mortar indicates the way to the dispensary and doctor's surgery. But apart from pestilence or accident illness is likely to be infrequent on a vessel designed for healthy living, and the abundant store of pills will not rapidly diminish where sport and exercise are available for everyone.

ETHICAL PHARMACEUTICALS ASSOCIATION (E.P.A.)

A NUMBER of firms representing manufacturers of ethical pharmaceutical preparations—i.e., preparations not advertised to the public—have formed themselves into an association to represent this particular branch of the pharmaceutical trade. The chief objects of the Association are to represent and conserve the interests of the members, to afford a means of exchange of views in matters of mutual concern, and, in general, to act on behalf of members on all trade matters. The secretary of the Association, Mr. J. E. Woodhead, B.Sc., F.I.C., may be addressed at Coronation House, 4, Lloyd's-avenue, London, E.C.3.

FUMIGATION WITH HYDROGEN CYANIDE

A FEW weeks ago a fatal accident during the fumigation of vermin-infested cottages directed public attention to the exceedingly poisonous character of hydrocyanic acid gas, but, as we pointed out[1] at the time, "so valuable is this method of destroying rats and vermin that, in spite of its dangers, prohibition of its use is inadvisable." It is however a misfortune that the Ministry of Health has no statutory power to make regulations for the control of fugimation. We have now received from the London Fumigation Co., Ltd. (Marlow House, Lloyd's-avenue, E.C.3), a little brochure assembling facts about hydrocyanic acid which may be of practical assistance to sanitary inspectors. The primary object of the booklet is the excellent one of fortifying the inspector with sufficient knowledge to enable him to gauge the competency of a fumigation service or to undertake the work himself. The particular preparation of hydrocyanic acid for which this firm is responsible is known as Zylon, and contains a lacrymator with a pronounced smell, for it is found in practice that a number of people do not recognise the smell of hydrocyanic acid until a dangerous concentration is reached. This added lacrymator being heavier than HCN lingers in the atmosphere longer than the HCN itself. The pamphlet contains directions what to do when HCN has been inhaled, for it is seldom, the pamphlet says, that the practical fumigator does not experience at some time or other a single inhalation of a fairly strong concentration or a prolonged exposure to lighter concentrations.

---

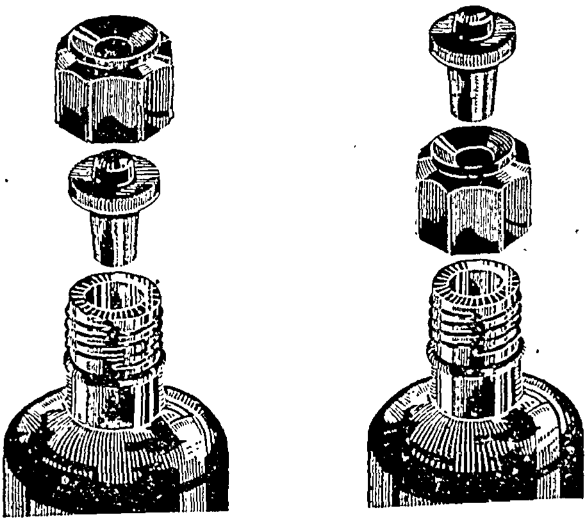
NEW PREPARATIONS

Luizym.—This preparation of digestive enzymes is manufactured at the Luitpold works in Munich and is put on the market by Medical Laboratories, 40, Pall Mall, London, S.W.1. It is stated to give relief in cases where there is an excessive formation of gas in the intestine after eating various vegetables and fruits and farinaceous foods and potatoes. The medical support given to the use of the preparation is set out in a communication from A. E. Lampé and A. Schmidt-Ott, Munich, in the *Münchener medizinische Wochenschrift*, where its use in cases of flatulent colic is stressed. The preparation, which has a savoury flavour, is made up in tablets, and the container, which is opaque as a precaution against the action of light, should be kept in a cool dry place.

Veganin Brand Tablets.—This preparation is put on the market by Messrs. William R. Warner and Co., Ltd., 300, Gray's Inn-road, W.C.1. It is made up in tablets, each of which contains codeine phosphate (poison) 0·01 g., phenacetin 0·25 g., acetylsalicylic acid 0·25 g., excipient 0·09 g. The combination of antipyretic, local analgesic, and sedative is claimed to be useful in the relief of pain, particularly in inflammatory conditions of the ear, nose, and throat, and in neuralgia and dysmenorrhœa.

THE COLLOSEAL: NEW CAPPING DEVICE

We have received a bottle from The Crookes Laboratories, Park Royal, London, N.W.10, containing a specimen of their well-known Collosol Manganese, but the interest attached in this case to the sample lies in its stopper, the "Colloseal." The accompanying picture illustrates an ingenious device incorporating the advantages alike of a stopper and cap, which, we are informed by the firm, will now be fitted to all Collosol aqueous solutions.



Appointments

Blauvelt, H. O., F.R.C.S. Eng., has been appointed surgeon (Grade 2) at the North Middlesex County Hospital.

Davies, D. T., M.D., F.R.C.P. Lond., assistant physician to the Hospital of St. John and St. Elizabeth, London.

Davies, Woodfield, L.M.S.S.A., anæsthetist to the British Postgraduate Medical School.

Erwin, G. S., M.B. N.Z., resident medical officer at the Hospital for Consumption, Brompton.

Gregory, Philip, M.B. Manch., hon. surgeon in charge of the Eye Department of the Infirmary, Stockport.

Housden, G. M., M.B. Lond., assistant anæsthetist at the Miller General Hospital, Greenwich.

Howat, H. T., M.B. St. And., resident clinical pathologist at the Manchester Royal Infirmary.

Kilner, T. Pomfret, M.B. Lond., F.R.C.S. Eng., consulting surgeon to the Hospital for Tropical Diseases, London.

MacLachlan, I. M., M.D. Durh., B.Hy., D.P.H., tuberculosis officer and senior assistant medical officer of health for Portsmouth.

Moore, A. M. A., F.R.C.S. Eng., assistant surgeon at the King George Hospital, Ilford.

Morgan, C. Naunton, M.B. Lond., F.R.C.S. Eng., surgeon to the Hospital for Tropical Diseases, London.

O'Sullivan, J. V., M.D. N.U.I., F.R.C.S. Eng., M.R.C.P. Lond., M.C.O.G., assistant visiting obstetrician at the Kingston and District Hospital.

Rait-Smith, B., M.R.C.S. Eng., anæsthetist to the British Postgraduate Medical School.

Seekings, T. A., M.D. Lond., D.P.H., medical officer of health and port medical officer for Barrow-in-Furness.

Simpson, S. Levy, M.D., M.R.C.P. Lond., hon. assistant physician to the Princess Louise Kensington Hospital for Children.

Walker, F. H. Aitken, B.Chir. Camb., F.R.C.S. Eng., surgical registrar at the Royal Berkshire Hospital, Reading.

Williams, Marion, M.R.C.S. Eng., anæsthetist at the Miller General Hospital, Greenwich.

London County Council Hospital Staff.—The following appointments, promotions, and transfers are announced. A.M.O.(I.) =Assistant medical officer, Grade I. D.M.Sup. (II.) = Deputy medical superintendent, Grade II.

Henderson, R. G., M.D., D.P.H., D.M.Sup.(II.), Park Hospital;
Hunter, A., M.D., D.P.H., D.M.Sup. (II.), Grove Hospital
Thompson, A. R., M.D., D.P.H., A.M.O.(I.), South-Eastern Hospital.

Certifying Surgeons under the Factory and Workshop Acts: Dr. G. H. **Dymond** (Hammersmith, Middlesex); Dr. M. **MacCulloch** (Alloa, Clackmannan); Dr. J. R. E. **James** (Carmarthen District, Carmarthen); Dr. G. B. **Sleigh** (Alyth, Perth).

Births, Marriages, and Deaths

BIRTHS

Bowesman.—On August 15th, at Billericay, the wife of Reginald Bowesman, M.B. Dub., of a son.

Crowe.—On August 12th, the wife of W. Nigel Crowe, M.D. Durh., Headingley, Leeds, of a son.

Farr.—On August 10th, at Hong-Kong, the wife of F. J. Farr, M.B. Brist., of a son.

Gourlay.—On August 17th, at Bentinck-street, to Janet Vaughan, D.M. Oxf., wife of David Gourlay, Gordon-square, W.C.—a daughter.

Green.—On August 14th, at Banff, the wife of Herbert J. Green, M.B. Aberd., of a son.

Smyth.—On August 11th, at Harley-street, W., the wife of Michael Smyth, F.R.C.S. Eng., of a daughter.

Stewart.—On August 10th, at Welbeck-street, W., the wife of Harold Stewart, B.Chir. Camb., of Barnet, of a son.

MARRIAGES

Alston—Sandes.—On August 16th, James Maxwell Alston, M.B., M.R.C.P. Edin., to Gladys Maud Sandes, B.S., F.R.C.S. Eng.

Bridge—Hann.—On July 27th, at Hampstead, John C. Bridge, C.B.E., F.R.C.S. Edin., to Joan Phyllis Hann, daughter of Mr. James S. Hann, of Finchley.

Reckitt—Taylor.—On August 10th, at Christ Church, Lancaster Gate, Vincent Booth Reckitt, M.B., B.S. Lond., to Mary (Mollie), second daughter of Mr. Harrison Taylor, of South Croydon.

DEATHS

Anderson.—On August 17th, at Dundee, John Anderson, D.S.O., M.B. Aberd., F.R.C.S. Edin., professor of surgery at St. Andrew's University, aged 49.

Wyncoll.—On August 11, at Eastbourne, John William Wyncoll, M.B. Edin.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Mental Welfare Centre.—A mental welfare centre, the first to be inaugurated in Yorkshire, has been opened in Leeds and will serve the Wakefield Mental Hospital area.

STUDENTS' GUIDE—SESSION 1935-1936

THE GENERAL MEDICAL COUNCIL

POWERS, DUTIES, AND CONSTITUTION

THE General Council of Medical Education and Registration of the United Kingdom is, first, a registering body: no person, even though his qualifications have been obtained by examination, is a *legally qualified* medical practitioner until his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that there is a definite minimum of medical education and scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner convicted of felony or misdemeanour or adjudged guilty of professional misconduct. Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council consists of 39 members, of whom 18 are appointed by universities and 9 by licensing corporations; 5 members are chosen by the Crown on the advice of the Privy Council, and 7 others are elected by the members of the medical profession as Direct Representatives. The Crown members and the university representatives need not be medical men, and one layman appointed by the Privy Council now sits on the Council. Three members are appointed for dental business by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom.

The Educational Curriculum

Professional Education.—The course of professional study after registration as a student occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

REGISTRATION OF MEDICAL STUDENTS

Before registration as a student every candidate must produce evidence that (*a*) he has attained the age of 17 years; (*b*) that he has passed a recognised examination in general education; and (*c*) that, *in addition thereto*, he has passed, or obtained exemption from, an examination, theoretical and practical, in elementary physics and elementary chemistry conducted or recognised by a licensing body. The standard of General Education required is approximately that of University Matriculation or entrance examination in the Faculties of Arts or Pure Science. Examinations, other than Matriculation, must be of the standard prescribed in Section 2 of the Regulations below.

An approved course of instruction in elementary biology at a secondary school or other teaching institution recognised by a licensing body may admit a student to the professional examination in elementary biology upon registration as a medical student. The student should in every case write beforehand to the Body whose qualification he desires to obtain, and, although it is not necessary to pass in Biology before registration as a student, application should be made at the same time to the Body selected to ascertain their requirements.

The candidate commencing medical study should apply to the registrar of the division of Great Britain and Ireland in which he is residing, according to a prescribed form copies of which may be had on application to the several licensing bodies, medical schools, and hospitals, or at the offices of the Council; and should produce proof that he, or she, has fulfilled the first three conditions.

MAINTENANCE OF REGISTER OF MEDICAL STUDENTS

1. The Education Committee prepares and issues from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are recognised by, the Council.

2. The Council has recognised the undernoted university examinations which are conducted in Great Britain and admit to the Faculties of Arts or Pure Science, or to other Faculties, subject to the conditions specified below:—

Oxford University, Responsions; Cambridge University, The Previous Examination. The Matriculation Examinations of the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Victoria of Manchester, Sheffield and Wales, and the Entrance or Preliminary Examination of the Universities of Scotland.

The condition prescribed by the Council in Faculties other than Arts or Pure Science is that:—

The certificate shall bear evidence that the candidate has passed at the Matriculation or Entrance standard in the following subjects, viz.: (*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) A fourth subject, as defined in the regulations of the particular Examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science, Botany: Latin, Greek, Hebrew, French, German, or other language accepted by the University.

3. Subject to the condition prescribed above (Section 2), the Council will recognise those of the examinations conducted by recognised authorities in Great Britain which are accepted by any *one* or more of the above-named Universities as equivalent (under prescribed conditions as to "credits" or "grades"), for purposes of Entrance or Matriculation, to an Examination named in the preceding list (Section 2). In School or Leaving Certificates, the four required subjects must have been obtained at not more than *two* sittings. Such Examinations are:—

Bristol University: Higher School Certificate Examination; School Certificate Examination. Cambridge Local Examinations Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Higher Certificate Examination; School Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: Higher School Certificate Examination; General School Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

4. The Council will continue to recognise certain Examinations conducted by Educational Bodies, other than those (mentioned in Section 3) whose Examinations are accepted by any one or more of the Universities of Great Britain. Recognition will not be extended under this Section to any Examination unless the Council is satisfied (*a*) that in scope and standard it is equivalent to a recognised Matriculation or Entrance Examination of a University of Great Britain, (*b*) that it fulfils the condition prescribed by the Council (Section 2), and (*c*) that the Examination has been completed at not more than two sittings. Such Examinations are:—

The College of Preceptors (England): Senior Certificate (with *credit*). The Educational Institute of Scotland: Preliminary Medical Certificate.

5. Subject to the prescribed condition (Section 2), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, and the Matriculation or Entrance Examinations of the National University of Ireland, the Queen's University of Belfast, the Irish Royal Colleges of Physicians and Surgeons; and also the Senior Grade or Leaving

Certificate of the Department of Education of the Irish Free State, the Senior Certificate Examination of the Ministry of Education of Northern Ireland, and all examinations accepted by any one or more of the Universities of Great Britain or Ireland, as equivalent, for purposes of entrance or matriculation, to the above-named University Examinations.

6. Subject to the prescribed condition (Section 2), the Council will recognise all Examinations of Colonial or Foreign Universities which are accepted by any one or more of the Universities of Great Britain as equivalent for purposes of entrance or matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

7. The Council will recognise the Final Examinations for Degrees in Arts or Science of any University of Great Britain or Ireland or of the British Dominions.

8. The registration of medical students is placed under the charge of the Branch Registrars.

9. Each of the Branch Registrars keeps a register of medical students.

10. The Branch Registrar enters the student's name and particulars in the Student's Register, and gives him a certificate of such registration.

11. Each of the Branch Registrars supplies to the several licensing bodies, medical schools, and hospitals, in that part of Great Britain or Ireland of which he is Registrar, blank forms of application for the registration of medical students.

12. A copy of the Medical Students Register prepared by each of the Branch Registrars is transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who distributes the list to the licensing bodies, medical schools, and hospitals.

All applications for special exceptions to the foregoing regulations as to registration should be addressed to the Registrar of the General Council, and are decided by authority of the Education Committee, who report thereon to the Council.

MEDICAL SCHOOLS AND COLLEGES

The Universities, including their Colleges and Medical Schools, and Schools of Medicine at which Medical Study may be commenced in the United Kingdom are set out seriatim in the following pages.

Medical Registration in Ireland

By legislative agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland—the powers and duties of the General Council of Medical Registration and Education are continued as heretofore in respect of qualifying bodies in the Irish Free State, and of medical practitioners qualified in the Irish Free State. Side by side with this a Medical Council has been set up in the Irish Free State with the duty of establishing and controlling a Register for the Irish Free State. Practitioners whose names are on the General Register, and persons who pass a qualifying examination in the Irish Free State, will be registered on the Irish Free State Register on payment of the prescribed fee. The Irish Free State Medical Council have, over those whose names are on the Irish Free State Register, the same disciplinary powers as are possessed by the General Council over those whose names are on the General Register. To possess the privileges of a qualified practitioner in the Irish Free State it is necessary to be registered in the Irish Free State Register.

The net result of the change in the law as regards the practitioner qualifying in the Irish Free State in the future is that: (1) if he intends to practise only in the Irish Free State he need only register in the Irish Free State Register; (2) if he intends to practise in Great Britain he will register in the General Register; and (3) if he is in doubt where he will practise he will register in both Registers. He will, as he registers in one Register, or in both Registers, put himself under the disciplinary control of the one Council or of both Councils. No practical inconvenience is caused, and practitioners qualified in the Irish Free State in future will not find themselves deprived of any former privileges or rights.

Dental Board of the United Kingdom

Anyone who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without a degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available, and, unless the practitioner is on the Dentists Register, no work can be undertaken under the National Health Insurance (Dental Benefit) Regulations.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the power to erase a name from the Dentists Register, remain with the Council, but the inquiry into disciplinary cases rests with the Board, who forward their reports and findings to the Council.

The Dental Board consists of a chairman and 12 members. The chairman is appointed by the Privy Council. Other members of the Board are appointed by the Minister of Health, the Department of Health for Scotland, the Governor of Northern Ireland, the General Medical Council (3), four members are elected as representatives by the dentists possessing degrees or licences in dental surgery or dentistry, and practising in England and Wales, Scotland, and Ireland, and two by dentists registered under the Dentists Act, 1921.

REGISTRATION OF DENTAL STUDENTS

The General Medical Council's Regulations in regard to the registration of dental students have recently been revised. The new regulations came into force on Oct. 2nd, 1933, and provide that the registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and be subject to the same regulations as regards age and preliminary examinations; but professional study may commence either at a recognised dental hospital or school, or by pupilage with a registered dental practitioner.

Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in dental mechanics. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study. When a student can show evidence of regular pupilage for not less than two years in dental mechanics to a registered dentist, prior to the passing of the prescribed preliminary and scientific examinations, he may antedate his registration for a period not exceeding one year prior to the passing of these examinations.

Offices

The address of the Registrar, to whom further communications should be addressed, is as follows: The Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W.1. The offices of the Dental Board are at the same address.

A memorandum on the procedure to be adopted by those who desire to enter the profession of medicine, with notes on costs and prospects, and a similar memorandum in regard to dentistry, may be obtained on payment of 1s. each.

MEDICAL EXAMINING BODIES AND SCHOOLS IN ENGLAND AND WALES *

UNIVERSITY OF OXFORD

THERE are two degrees in Medicine, *B.M.* and *D.M.*, two in Surgery, *B.Ch.* and *M.Ch.*, and a diploma in *Ophthalmology*. The examinations are open to men and women alike.

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Animal Physiology.

To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary subjects: Physics and Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine and Public Health, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The First B.M. Examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing *First B.M. Examination*, the candidate can, on producing certain certificates, present himself for examination in the subjects of Pathology, Forensic Medicine and Public Health, Materia Medica and Pharmacology; but cannot, unless he is already a registered medical practitioner, enter for Examination in Medicine, Surgery, and Midwifery, until the eighteenth term from his matriculation, nor until a period of at least thirty-three months has elapsed from the date of passing the First B.M. Examination. He must pass in Medicine, Surgery, and Midwifery at one and the same time.

Before admission to the Examinations in Pathology and Bacteriology, and Materia Medica and Pharmacology, of the *Second B.M. Examination*, the student must produce certificates of having attended courses of instruction including practical work in Pathology, Bacteriology, Post-mortem Clerking, and Pharmacology, either in Oxford or in another recognised Medical School. Before admission to the remainder of the Second B.M. Examination, he must produce a number of other certificates, including evidence of having acted as Clinical Clerk and Dresser, each for six months in the Wards, of instruction in Midwifery and of attendance on Labours, of instruction in Infectious Diseases and in Ophthalmology, of proficiency in Vaccination and in the administration of Anæsthetics, and of three academic years of hospital practice.

The degree of Bachelor of Surgery (B.Ch.) is granted with that of B.M. after passing the above examinations.

The degree of Doctor of Medicine (D.M.) is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by judges appointed for the purpose by the Board of the Faculty of Medicine. The degree of Master of Surgery (M.Ch.) is granted after examination to Bachelors of Surgery who have entered upon their twenty-first term, and who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology, and Surgical Operations, is held annually in June, after the Second B.M. Examination.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Schorstein Research Fellowship of the value of £200 a year, tenable for two years, is offered in alternate years. Candidates must be graduates of the University, under 35 years of age, and must hold a registrable medical qualification. Their research must be carried out in one of the Medical Departments at Oxford. A Christopher Welch Scholarship of usually £200, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A George Herbert Hunt Travelling Scholarship of the value of about £100 is awarded every second year to enable a Bachelor of Medicine to undertake three months' study abroad. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships are awarded annually in the subjects of Anatomy, Physiology, and Pathology; the two first are of the value of £50 a year for two years, the last of the value of £60 a year for two years. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. Scholarships at certain London hospital medical schools are awarded each year on the nomination of the Regius Professor of Medicine. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships varies, according to the candidate's need, between £30 and £100 a year; the exhibitions vary in value from £30 to £80 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £4.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, latest edition; from the Regius Professor of Medicine; from the Professors in the departments of medical science; and from the Dean of the Medical School, Department of Medicine, University Museum, Oxford.

The Radcliffe Infirmary

There are 389 beds. Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) clinical lectures by the Litchfield Lecturers in Medicine and Surgery; (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation; and (4) pathological demonstrations and instruction in post-mortem work are given by the Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. A post-graduate course is held in the hospital in the autumn of each year.

---

* For special diplomas see p. 529.

UNIVERSITY OF CAMBRIDGE

There are two degrees in Medicine, *M.B.* and *M.D.*, wo in Surgery, *B.Chir.* and *M.Chir.*, and a Diploma n *Medical Radiology and Electrology.* Students of Girton or Newnham College are admitted to the examinations for these degrees and the diploma.

The student must enter a College, or become a Non-Collegiate student, and keep nine terms (three years) by residence. He must pass the Previous Examination of the University before he comes into residence or therefrom obtain exemption, particulars of which may be obtained from the Registrary. He may then devote himself to medical study in the University. Under new regulations it is necessary for a candidate to take an Honours degree in Arts by passing one or more Tripos Examinations. The Natural Sciences Tripos is taken most frequently by medical students, for if the required standard is reached in Anatomy and Physiology in this Tripos no further examination is required in those subjects. The student must in addition take one more subject or two half-subjects. Pathology and Biochemistry, which are of great practical importance to medical students, can both be taken as half-subjects. If a student fails to reach an honours standard, he is required to take the examination in a subsequent year before he can proceed to the Final M.B. Examination.

For the degree of Bachelor of Medicine (M.B.) five calendar years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three years are spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the *First Examination* and other preliminaries to the *Final Examination.* Hospital practice may be attended at Addenbrooke's Hospital, Cambridge. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, and Psychology are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

The *First M.B. Examination* includes (1) General and Inorganic Chemistry, (2) Physics, (3) Elementary Biology, and (4) Inorganic Chemistry. These parts may be taken together or separately. After the First Examination, and tests in Pharmacology, Physiology, and Anatomy, comes the *Final Examination*, divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept by the candidate reading an original dissertation composed by himself, and being examined orally, on some subject approved by the Regius Professor of Physic. Candidates who have passed both parts of the Final M.B. Examination are admitted to the registrable degree of Bachelor of Surgery (B.Chir.) without separate examination and without keeping an Act.

The degree of Doctor of Medicine (M.D.) may be taken by a graduate of the University of eight years' standing who has passed the Final M.B. Examination. An Act has to be kept, consisting of an original Thesis with viva-voce examination; and an examination, oral or written or both, on the field of Medicine within which the Thesis falls may be allowed or required.

Candidates for the Degree of Master of Surgery (M.Chir.) who are M.A.'s may be admitted to the examination after they have become legally qualified under the *Medical Acts* to practise surgery. Others may be admitted to the examination when two years at least have elapsed after they have completed all that is required of candidates for the Degree of B.Chir. Candidates are required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. (The examination is held in February.)

A Diploma in Medical Radiology and Electrology is granted. Candidates must hold a recognised medical qualification.

Scholarships and Prizes.—Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors. There are Natural Science scholarships at most of the Colleges and prizes in the ancillary medical subjects. Some of these are entrance scholarships; some may be gained by students already in residence, and where suitable candidates are not forthcoming among such students the emoluments may be allotted to members of other Colleges. Valuable scholarships instituted on behalf of Medicine are the Tancred Studentships in Physic, tenable at Gonville and Caius College. The successful candidates must enter at the college within a month or remove there if they are members of any other college. Students are required to take the degree of M.B. as soon as they are of sufficient standing but may hold a Studentship for a further three years. Thus a student elected previous to admission to college can draw the emolument, the annual value of which is about £100, for eight years. Full particulars can be obtained from Mr. E. T. Gurdon, 28, Lincoln's Inn-fields, London. Among other scholarships and prizes may be mentioned the Balfour Studentship, for research in Biology, of the value of £300 a year for three years, not restricted to members of the University; the Frank Smart Studentship and Prizes for Botany and Zoology; the Shuttleworth Studentship for Zoology or Physiology tenable at Gonville and Caius College; and the Marmaduke Shield Scholarship in Human Anatomy. The one University prize in Medicine, the Raymond Horton Smith Prize, is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a Tripos Examination. The E. G. Fearnsides Research Scholarship and several very valuable studentships are also awarded.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon application to the Registrary, The Registry, Cambridge.

Addenbrooke's Hospital

312 beds. Clinical lectures in medicine and surgery, in connexion with Cambridge University medical school, are given at this hospital during the academical year; and practical instruction in medicine and surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations.

UNIVERSITY OF LONDON

The University of London was constituted in 1836, reconstituted under Act of Parliament, 1898, as a teaching as well as an examining body, and again reconstituted under Act of Parliament, 1926. All the metropolitan medical schools are constituent colleges, while Clinical Units have been established at St. Bartholomew's, the London, St. Mary's, St. Thomas's, University College Hospital, and the Royal Free.

A revision of the medical curriculum is under consideration, in view of a report submitted to the Senate by a Conference of representatives nominated by the Universities of Oxford, Cambridge, and London, the English Royal Colleges, and the Society of Apothecaries.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who are registered as pursuing a prescribed course of study, or an approved course of research, in a school of the University, or under teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. External students in addition to matriculating must register as preparing for an examination leading to a Degree or Diploma within the purview of the Council for external students.

UNIVERSITY COLLEGE

University College is a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the departments of physics, chemistry, botany and zoology (the Preliminary Medical Sciences); also the departments of anatomy and embryology, physiology, biochemistry, and pharmacology (the Intermediate Medical Sciences). Post-graduate and research work is undertaken in all departments. The completion of the building scheme by the erection of the section for anatomy, histology, and embryology, together with further extensions to the department of physiology, biochemistry, biophysics, and pharmacology, and the provision of new accommodation for the department of zoology, which the generosity of the Rockefeller Foundation made possible, provides exceptional facilities for research and post-graduate study. The opportunities for investigation in human and comparative embryology and neurology, in histology, radiology, anthropology, biochemistry, and experimental physiology and embryology may be mentioned. In the department of zoology and comparative anatomy, the study of genetics accompanies that of comparative physiology and animal behaviour. Arrangements exist for the close correlation of the work of the Faculty with University College Hospital and Medical School. Women students are admitted.

Scholarships and Prizes.—The first four items on the present list provide a complete intermediate course at University College, and, in the case of (*a*), the later clinical stages at University College Hospital. The money value and subjects at examinations are as follows: (*a*) Bucknill Scholarship, 160 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, Zoology, and an English essay; (*d*) Entrance Scholarship, £30 a year for three years; (*e*) Ferriere Scholarship, £25 for three years, tenable at University College Hospital Medical School, awarded to a student who has done his Anatomy and Physiology at University College and has completed the 2nd Medical Examination; (*f*) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, Pharmacology, and Chemistry; (*g*) Schafer Prize in Physiology, £18 triennially; (*h*) Sharpey Physiological Scholarship, about £112, Biological Sciences; (*i*) Bayliss-Starling Scholarship, £120 a year, Physiology, Biochemistry; (*j*) Percy F. Macgregor Research Scholarship in Embryology, £50; (*k*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £20 a year; and (*l*) two Gold Medals awarded annually in Anatomy and Physiology. For information apply to the Secretary, University College, Gower-street, London, W.C.1.

KING'S COLLEGE

The Medical Faculty at this College of the University gives instruction in the subjects of Medical Science for all the usual Preliminary and Intermediate Examinations in Medicine and Surgery. Through the four associated hospitals, students of the College have clinical facility of over 1000 beds, but they may also proceed to any other teaching hospital in London for final studies for the degrees of the University.

The Medical Faculty of the College provides a general University education in touch with other Faculties, classes of which medical students are permitted to attend. There are many College societies, clubs, and functions, in which students of all faculties have opportunity of meeting each other. The College has a large athletic ground at Mitcham, upon which is a new pavilion.

The First Year subjects are taught in the large Departments of the Faculty of Science and those for the Second and Third Years in the new Medical Department, consisting of the Hambleden Department of Anatomy and an extension to the department of physiology, built at a cost of £70,000. These new buildings and others of recent years provide the College with a completely new and modern Medical Department which embodies the newest ideas in laboratory construction and equipment.

Scholarships and Prizes.—Two Warneford Entrance Scholarships of £30 each for four years. Examination in May, subjects selected from Divinity, Classics, Science. One Sambrooke Scholarship of £30 for three years. Examination in May, subjects selected from Classics, Science. Worsley Scholarships: £100 in five annual instalments of £20. *At the end of the First Year* of study, one Warneford Scholarship of £30 for four years, subjects as for First M.B.; the Rabbeth Scholarships (£30 and £15), the Carter Gold Medal and Prize in Botany, and the Hare Prize in Zoology are open for competition. *At the end of the Third Year*, the Hughes Prize in Anatomy, the Huxley Prize in Physiology, the Inchley Prize in Pharmacology, and the Jelf Medal are open for competition. The Layton and the Berridge Research Studentships (£150 and £100 per annum respectively), the Daniell Scholarship in Chemistry (£40), Warneford Prizes (£25 and £15), Leathes Prize, Barry Prize, &c., are also open to Students of this Faculty. The majority of the Scholarships and Prizes are open to Regular Students only. For information apply to the Dean of the Medical Faculty.

The Medical Faculty of the University

Medical students of the University of London who are pursuing their medical curriculum in the metropolis will proceed to one of the recognised medical schools connected with the University. The schools are described in detail in the next section: they are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. Students of St. George's, Charing Cross, and Westminster Hospitals take their preliminary medical studies at King's College. Students of the London Hospital usually attend East London College for the subjects of their first medical examination. Various schools and hospitals are also recognised as schools of the University in special departments, and students may pursue their studies at other approved universities and medical schools.

The Faculty of Medicine of the University grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*) and the degree of B.Pharm. (*Bachelor of Pharmacy*); the two higher degrees being open only to candidates holding the M.B., B.S. degrees of the University. The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) the First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and

Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year commencing on the Monday following Dec. 5th and on the first Monday in July. It must be passed not *less than nine months after matriculation.*

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Thursday following the second Monday in March and on the Thursday following the first Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate will be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory courses in (1) Clinical Medicine; (2) Clinical Surgery; (3) Clinical Pathology; and the following: Experience as Clinical Clerk; course in Clinical Medicine; (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; Experience as a Surgical Dresser; course in Clinical Surgery; Ophthalmology; Oto-Rhino-Laryngology; (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery, (*f*) Mechano-therapeutics; Obstetrics and Gynæcology; Lying-in Hospital; the conduct of at least 20 Labours; Ante-natal Clinic; Experience as a Clinical Clerk in Gynæcological Work; General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; Work in the Post-mortem Room; Clinical Laboratory; Forensic Medicine; Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics, and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology, and may be taken either separately or together.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) Hygiene; and (6) Tropical Medicine. Any candidate may transmit to the Registrar a thesis for approval and may be exempted from a part or from the whole of the written examination, and in the case of Branch II. (Pathology) also from the practical examination.

Master of Surgery.—The examination for the degree of Mastery of Surgery takes place twice in each year: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology, and Rhinology. A thesis may be submitted as for M.D.

Doctor of Philosophy.—A Degree of Ph.D. has been instituted in non-clinical subjects for Internal and External Students in the Faculty of Medicine. Candidates for this degree must hold, in a branch of study akin to that in which they propose to proceed to the Ph.D. Degree, the Degree of M.B., B.S., or B.D.S., or B. Pharm., or B.Sc.

Bachelor of Pharmacy.—This is a three years' course.

Full details of the prescribed curricula can be obtained free on application to the *Academic Registrar*, or for External Degrees from the External Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON

St. Bartholomew's Hospital and College

The hospital contains 762 beds, of which 692 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. Special departments have been organised for diseases of women and children, the eye, ear, larynx, and skin, as well as for orthopædic and dental surgery, and for electro-therapeutics and X ray work. Whole-time Clinical Units under professors of medicine and surgery have been established. A new surgical block of ten wards, with accommodation for 250 patients, and connected with a block of five new operation theatres is now in use.

Ten house physicians and ten house surgeons are appointed annually, are provided with rooms and board, and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear, and a house surgeon for orthopædic surgery are appointed every six months, and are provided with rooms and board and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the College as well as a laboratory devoted to instruction in public health. A block is devoted to pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical College Buildings* include three large lecture theatres, a large dissecting-room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is complete. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

The College has recently bought the site and buildings in Charterhouse-square (five minutes' walk from the Hospital), formerly occupied by The Merchant Taylors' School, and the whole of the preclinical departments will shortly be transferred there.

Special Classes for the Primary and Final F.R.C.S. Examinations are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. Facilities for research work are afforded in the Clinical Units and laboratories of pathological and other departments. *Vacation Anatomy Courses* are given in winter, spring, and summer.

Scholarships given in aid of Medical Study.—Six Entrance Scholarships and Exhibitions are awarded annually—viz.: (1) and (2) a Scholarship entitling the holder to free undergraduate medical education for a period of three years; and an Exhibition of £60 in any two of the following subjects: Human Anatomy and Embryology, Physiology, Pathology (including Bacteriology), Biochemistry; (3) a Scholarship of £100 in Chemistry, Physics, and Biology; (4) and (5) a Scholarship of £100 and the Jeaffreson Exhibition of £50 in Mathematics, Latin or Greek or French or German, a second language or Chemistry or Physics; (6) Helen Cave Memorial Scholarship, awarded after open competition to sons of Registered Medical Practitioners, value about £200, conditions obtainable from the Dean; (7) Shuter Scholarship of £50 in Anatomy and Physiology, which is awarded after competitive examination among Cambridge Graduates. The more important of the other Scholarships and prizes are as follows: Four Junior Scholarships—(8) No. 1, £30, Anatomy and Physiology; (9) No. 2, £20, Anatomy and Physiology; (10) No. 3, £25, Chemistry, Physics, and Biology; (11) No. 4, £15, Chemistry, Physics, and Biology; (12) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (13) Kirkes Scholarship, £30 and medal, Clinical Medicine; (14) and (15) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (16) Sir G. Burrows Prize, 10 guineas, Pathology; (17) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (18) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (19) Luther Holden Research Scholarship in Surgery, awarded by election, £105; (20) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115; and (21) Baly Scholarship in Clinical Medicine, £75, awarded by examination.

The recreation ground of 10 acres, for the use of the members of the Students' Union, is at Winchmore Hill. The Union's premises at the Hospital contain a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range. Athletic amenities are also available on the new site in Charterhouse-square.

Charing Cross Hospital

The Hospital, to which the School is attached, contains 300 beds. The School has just celebrated its centenary, accompanied by a public appeal for £50,000 which is still open. The facilities offered are complete. In addition to a full complement of medical and surgical beds, there are special departments for mental diseases, midwifery, diseases of women, of children, of the skin, ear, throat, nose, and teeth, for orthopædic cases, X ray work, and for electrical treatment. The Casualty Department deals with an average of 20,000 new cases each year. Every student holds appointments as Clerk or Dresser in every department. In the medical school demonstratorships and assistant demonstratorships are open to students of the school. Eight house physicians, six house surgeons, two obstetric and gynæcological house surgeons, six house surgeons to the special departments, two resident anæsthetists, and four clinical pathologists are appointed annually. The following Senior appointments are open to students after they have held resident appointments: resident medical officer, at a salary of £400 per annum; resident casualty officer, at £200 per annum; and five registrars to the medical, surgical, obstetrical, and ear, nose, and throat departments.

Primary and Intermediate students receive their lectures and practical work at King's College, and final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged in general and special subjects.

In the Institute of Pathology, under a whole-time staff of scientific workers and in fully equipped laboratories, students receive their training in preventive medicine, pathology, and bacteriology. There are special facilities for research, and post-graduate teaching is available. The course in practical ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Courses in general medicine, surgery, and pathology, with the requisite clinical work in the wards and out-patient departments, are provided for students reading for dental qualifications.

The pathological museum, containing over 4000 specimens and 3000 histological preparations, comprises (1) the section on general pathology, and (2) the Cuthbert Lockyer Collection of over 1150 gynæcological and obstetrical specimens. The library contains 3950 volumes including the latest editions of text-books.

Scholarships and Prizes are offered annually: (*a*) for students commencing medical studies—two scholarships, each of the value of £50; (*b*) for students commencing clinical studies—two "University" scholarships, each of the value of £120, in Pathology; one "University" scholarship value £120, and one "Open" scholarship, value £75, in Anatomy and Physiology. There are a number of Exhibitions, and the following prizes are offered: (1) "Llewellyn" Prize, £25, for highest distinction throughout the final course of studies; (2) "William Travers" Prize, £15; (3) "J. H. Morgan" Prize, £10; other prizes in money are the "Pereira," "T. H. Green," and "Stedman," while prizes in money are offered for proficiency in clinical medicine and surgery, and all the different subjects of the curriculum.

The Students' club, with smoking and luncheon rooms on the school premises, cloak room, telephone, &c., provides for the social comfort and convenience of the students. The club is controlled by a committee of students, and includes the Medical Society and the Dramatic Society. The *Gazette* is published quarterly. The sports ground, of 8 acres, at Colindale affords facilities for Rugby and Association football, cricket, hockey, and tennis (hard and lawn courts). In addition there are sections of the club devoted to athletics, boxing, swimming, golf, and badminton.

St. George's Hospital

Plans are being prepared for the complete re-building of the whole of the Hospital and Medical School on its present site, and it is hoped that the new hospital will contain at least 450 beds and a much larger Medical School. In the meantime the work of the Institution will be continued unaltered.

This hospital has now a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. There are all the usual special clinical departments. One ward is set apart for diseases peculiar to women, and there is a maternity ward of 13 beds. One ward is set apart for the medical diseases of children. There are two ophthalmic wards.

Eight house physicians, ten house surgeons, and eight casualty officers are appointed annually. They are provided with board and lodging in the hospital and receive honorariums of £40 per annum. In addition the following appointments are open to all qualified students of the hospital: resident assistant physician at £250 per annum; medical officer to the Atkinson-Morley Convalescent Hospital at £300 per annum; medical registrarship at £200 per annum; two surgical chief assistants (resident) at £225 per annum; assistant curatorship of the museum at £100; obstetric assistantship (resident) at £100; the post of resident anæsthetist at £100.

The teaching and laboratories are devoted to clinical subjects, and arrangements have been made with the authorities of King's College and University College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at one of those Colleges. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Scholarships and Prizes.—At this school 11 entrance scholarships and exhibitions are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively; (*c*) and (*d*) two Anne Selina Fernee Scholarships, £80 each; (*e*) Devitt-Pendlebury Scholarship, £40 (approx.); (*f*) and (*g*) two Anne Selina Fernee Exhibitions, £60 each, Anatomy and Physiology, except in the case of (*c*) and (*f*) subject of examination for which is General Pathology.

In addition to the above, Exhibitions each of the value of £40 and up to four in number may be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*h*) Allingham Scholarship in Surgery for Students qualified not more than two years, £87; (*i*) and (*j*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing; (*k*) H. C. Johnson Memorial Prize, £20, Practical Anatomy; (*l*) Pollock Prize, £24, Physiology, Physiological Chemistry, and Histology; (*m*) Clarke Prize, £5; (*n*) Thompson Medal, £9, Clinical Reports; (*o*) Brodie Prize, £8, Clinical Reports; (*p*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*q*) Sir Francis Laking Memorial Prize, £45, open to students having registrable qualifications.

The Library is fully stocked with the latest and best text-books. The Pathological Museum has recently undergone complete revision. In addition to its well-known specimens of great historical interest, it contains a complete range of pathological conditions, set out in such a way that the student can easily obtain the fullest information relating to any disease.

The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Guy's Hospital

The Medical School, which has been entirely rebuilt within recent years, provides ample accommodation with modern equipment for all the subjects of the medical curriculum. The Hospital contains 647 beds. On commencing the clinical period, students are placed for three months under the charge of an experienced clinical tutor while they are given a preliminary course of instruction in methods of clinical examination. Thereafter they hold a series of appointments, each of three months' duration, in the surgical, medical, and obstetrical and gynæcological wards.

The following special departments are attached to the hospital: Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, psychological medicine, dermatology, otology, actino-therapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary, venereal diseases, and the Salomon's Welfare Centre (for maternity and children). There is a venereal clinic in accordance with the scheme of the Ministry of Health and the L.C.C.

House physicians, house surgeons, out-patient officers, assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology, laryngology, and genito-urinary diseases, house physicians in the departments for neurology and dermatology and for diseases of children, and clinical assistants are appointed from among recently qualified students according to merit.

Scholarships.—Five Entrance Scholarships are awarded annually and one every other year as follows: (*a*) one War Memorial Scholarship, of the value of £200, awarded alternately in Arts and Science (next award, April, 1936, in Arts); (*b*) one Open Arts Scholarship of £100 for students under 19 years of age, awarded annually in April; candidates are required to take English and any two of the following subjects: Latin, Greek, French, German, and Mathematics; (*c*) one Open Junior Science Scholarship of £100 for students under 20 years, awarded in April; subjects any three of the following: Inorganic Chemistry, Physics, Biology, and Mathematics; (*d*) a confined Junior Science Scholarship of the value of £100 is offered for competition annually, and is open to students who have attended the Preliminary Science Classes at this School. This Scholarship is awarded on the results of the First M.B. London Examination held in July; subjects: Chemistry, Physics, and Biology; (*e*) *University Entrance Scholarships:* (1) a War Memorial Scholarship entitling the holder to free medical education for three years, awarded annually in June or July; (2) an open exhibition of the value of £60, awarded annually in June or July, for students who have completed their examinations in Anatomy and Physiology in a British School or University outside the London Metropolitan area; subjects, any two of the following: Human Anatomy and Embryology, Physiology, Pathology including Bacteriology, Biochemistry. The examination is held in common with the Medical School at St. Thomas's Hospital and the Medical College of St. Bartholomew's Hospital.

Prizes.—The following prizes are awarded annually: (*a*) Treasurer's Medal and Prize for Clinical Medicine; (*b*) Treasurer's Medal and Prize for Clinical Surgery; (*c*) Golding-Bird Gold Medal and Scholarship (£20) for Obstetrics and Gynæcology; (*d*) Golding-Bird Gold Medal and Scholarship (£20) for Bacteriology; (*e*) Charles Oldham Prize in Ophthalmology (£30); (*f*) Beaney Prize for Pathology (£34); (*g*) Leonard Lubbock Prize for Clinical Pathology (£10); (*h*) Wooldridge Memorial Prize for Physiology (£10); (*i*) Sands-Cox Scholarship in Physiology (£45)—awarded triennially; (*j*) Prizes in Anatomy and Physiology for General Proficiency of the value of £20, £15, and £10 respectively; (*k*) Michael Harris Prize for Dissections (£5).

Studentships.—The following Studentships are open to graduates from this School: (1) Gull Studentship in Pathology (approx. £250 per annum); (2) Arthur Durham Travelling Studentship (£100)—awarded triennially; (3) Beaney Studentship in Materia Medica (£60 per annum); (4) Anderson Demonstratorship in Clinical Chemistry (£175 per annum); (5) Griffiths Demonstratorship and Research Studentship in Pathology (£320 per annum); (6) Adrian Stokes Fellowship in Pathology and Bacteriology (£300)—awarded biennially; (7) Hilda and Ronald Poulton Fellowship (£150 per annum).

The Wills Library contains 10,000 volumes of standard text-books and books of reference, the Museum contains upwards of 5000 specimens of pathological anatomy, supplemented by more than 2000 drawings.

Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a squash court, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 15 minutes from the hospital.

King's College Hospital

Instruction for the preliminary and intermediate examinations is given at the College.

The new medical school at Denmark-hill, opened in July, 1933, contains the Museum, Research Laboratory, Research Rooms, Common Rooms, Lecture Rooms, Refectory, and two Squash Rackets Courts. Provision is made for all the subjects of the medical curriculum. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are coördinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors. Twelve women medical students are admitted annually.

The numerous appointments open to students are those of clinical assistant to the general and special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers, house physicians, and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological; medical, surgical, obstetrical, and other registrarships. Thirty-one resident medical and surgical officers are appointed each year.

Post-graduate Courses.—Two advanced medicine and two advanced surgery courses are held annually, and are suitable for preparation for M.D., M.S., M.R.C.P., and F.R.C.S. Examinations.

An Evening Course for medical practitioners and senior students is held throughout the winter at 9 P.M. on Thursdays.

An Intensive Course is held on the first Saturday and Sunday of the winter session for qualified members of the School and other practitioners.

Scholarships.—Those in connexion with King's College have already been enumerated. Scholarships of the total value of £1530 are awarded annually. These include: (*a*) Medical Entrance Scholarships—Science, £75; Anatomy and Physiology, £75; Pathology, £75; (*b*) two Burney Yeo Entrance Scholarships, £105 each, open to students of Oxford and Cambridge on the recommendation of the Regius Professors; (*c*) two Raymond Gooch Scholarships, £105 each, open to students of British Universities on certain conditions; (*d*) Epsom College Scholarship, value £100, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London; (*e*) two Seaman Scholarships, each £50 a year for a period not exceeding five years, restricted to the sons of clergymen of the Church of England; (*f*) Senior Scholarship (Clinical Studies), £40. The holders of the Warneford and Sambrooke Scholarships take the subjects of the preliminary and intermediate examinations at King's College, and the final subjects at King's College Hospital.

Prizes.—Tanner Prize, £10, Obstetrics and Diseases of Women; Todd Prizes, first £8 and medal, second £4, for Clinical Medicine; Burridge Prize, £4 4s., Forensic Medicine; Jocelyn Almond Prize, £5 5s., Diseases of Children; Wallis Prize, £10, Dental Surgery; The Ferrier Prize in Neurology, Bronze Medal and £20; The Legg Prizes in Surgery and Surgical Pathology, Ware Prize for General Pathology, Cheyne Prize for Surgery. Special Prizes for Diseases of Children, Orthopædic Surgery, and Urology. Thirteen Class Prizes of £3.

Clubs, Hostel, Athletic Ground.—The King's College Hospital Clubs and Societies Union consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. The athletic ground, over six acres in extent, is on Dog Kennel Hill, about ten minutes' walk from the hospital. There are also tennis courts in the grounds of the hospital and of "The Platanes"—the residence for students on Champion Hill. The Library contains 7000 bound volumes in addition to the medical and scientific periodicals. There are good facilities for quiet reading and books are lent for use at home.

London Hospital

The hospital, with its Medical College and Dental School, contains 875 beds. Its neighbourhood to the extensive docks, factories, and workshops of the east of London is unrivalled, and presents an immense field for clinical instruction. There are special departments for the treatment of diseases of children, the eye, ear, nose and throat, skin and teeth. In addition there are departments devoted to gynæcology and obstetrics, orthopædics, cardiology, neurology, neurosurgery, radiology, electro- and physico-therapeutic light therapy, radium, and vaccine therapy.

A Clinical Unit in medicine, under the charge of a whole-time director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and coördination of medical research. The director has an assistant director, two assistants, and two house physicians.

To each medical and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of obstetrics and gynæcology there is a first assistant and two resident accoucheurs. In the department for children's diseases there is a first assistant, a house physician, and two clinical assistants. Special courses of lectures and demonstrations are arranged in medicine and surgery and their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

Many appointments are open to students before and after qualification, and holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, for the Membership of the Royal College of Physicians, and for other higher examinations. Special entries for medical and surgical practice can be made.

The salaried appointments open to past students of the hospital are those of assistants to the medical unit; first assistants to the medical and surgical firms; assistants to the departments of obstetrics and gynæcology; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopædic, neurological, neurosurgical, and electrical departments, and in the institute of pathology and clinical laboratory. There are appointed annually 4 resident accoucheurs, 16 resident house physicians and 19 resident house surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments.

Scholarships and Prizes.—Entrance Scholarships: Price Scholarship £100, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Scholarship of £50, in certain subjects of the Preliminary Examination in General Education; Price Scholarship, open to students of Oxford and Cambridge Universities, £100, Human Anatomy and Physiology; two Open Scholarships, each of the value of £100, subjects, Human Morphology and Embryology, Physiology and Pharmacology, Biochemistry, Pathology, Bacteriology, and Morbid Anatomy. Prizes: Buxton Prize, £40, subject of Anatomy and Physiology; H. L. B. Haking Prize in Clinical Obstetrics and Gynæcology, £25; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine and Surgery; Letheby Prizes (2), £25, Chemistry and Chemical Pathology; four Dressers' Prizes, amounting to £20, zeal, efficiency, and knowledge of Elementary Clinical

Surgery; Hutchinson Prize, triennial, £60, Clinical Surgery; Treves Prize, £20, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, £14, Clinical Medicine and Pathology; T. A. M. Ross (Prox. Acc.) Prize, £10 10*s.*, Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Diseases of Children; and Liddle Prize, triennial, £120.

Medical Research Funds.—Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in Medical Research.

A laboratory for the manufacture of certain preparations of Radium has recently been endowed.

A new Residential Hostel has been opened and provides accommodation for upwards of 50 students. The hostel includes a library, writing, common, and dining rooms, and two squash racket courts. There is also a hostel for resident medical officers. The Union Athletic Ground, 13 acres, is within easy reach of the hospital.

St. Mary's Hospital

The Hospital and Medical School have on one side a poor district of 500,000 persons, one-tenth of whom, on an average, pass through the hospital annually. On the other side are the residential districts of Kensington and Bayswater, making it possible for the student to live in touch with his work.

The hospital contains 384 beds, and recent structural additions have added two new operating theatres. By a scheme of affiliation, for teaching purposes, of certain neighbouring hospitals the teaching facilities extend over 1000 beds. The medical school provides courses of instruction for the teaching of the entire curriculum, and students can join at once on passing a preliminary examination in arts. Terms begin in October, January, and April.

Clinical Units in medicine and surgery were established in 1920. Under this system professors of medicine and surgery, with competent assistants, give their whole time to teaching and research. The system also provides additional salaried posts which are open to students after qualification.

The hospital has lying-in beds to which considerable additions have recently been made, and in addition to the instruction thus obtained each student attends a short course at Queen Charlotte's Hospital, as part of his training in Midwifery, without additional fee.

Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Research Scholarships of £200 each are awarded annually to students working in the departments, and research beds have been instituted. Clerkships in pathology, bacteriology, and chemical pathology, lasting for a period of three months, are open to students of the fifth year and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the medical school, including seventeen salaried posts with salaries varying up to £750 per annum. A special post-graduate course is held during the first week-end in October, and is open to all general practitioners and other qualified men without fee.

Entrance Scholarships.—From three to five Entrance Scholarships are awarded annually by nomination.

The Medical School and Institute of Pathology have been recently rebuilt at a cost of nearly £250,000. The buildings include a Students' Club and Restaurant with a swimming bath which opens on to a courtyard beneath which is a garage for 50 cars. There is a squash rackets court and gymnasium with a boxing ring.

The athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains.

Middlesex Hospital

The hospital and cancer wing contain over 560 beds, with special wards for cancer, maternity, gynæcological, otological, neurological, dermatological, and ophthalmological cases, and for diseases of children. Other special departments include those for diseases of the eye, ear, nose and throat, and skin; nervous diseases, orthopædic cases, diseases of the rectum, and venereal diseases. There is also an electrotherapeutic department and a department of radium therapy and research. Early in 1935 the Clinical Research Unit, known as the Courtauld Wards, was opened for the reception of patients upon whom investigations of a pathological, physiological, or biochemical nature are conducted. The cancer wing, containing 90 beds and special investigation laboratories, offers unrivalled opportunities for the study of cancer, both in its clinical and pathological aspects. In the electrotherapeutic department, students obtain instruction in the treatment of lupus and cancer by the X ray method of treatment.

The following appointments are made at intervals annually: eight house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one senior resident anæsthetist, two junior resident anæsthetists, four resident officers to the special departments, two dental house surgeons, and one clinical assistant to the Courtauld Wards. Nine registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

The medical school, which includes the Bland-Sutton Institute of Pathology, the Courtauld Institute of Biochemistry, the Barnato-Joel Laboratories, and the Ferens Institute of Otology, is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum and the University diplomas in radiology. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 professors, 2 university readers, 40 recognised teachers, 10 demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology and the Courtauld Institute of Biochemistry are completely equipped for routine hospital investigations, teaching, and research work, and contain large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped anatomical and pathological museum and reference library offer every facility.

Other features of interest are: the course in medical radiology and electrology, under the direction of the "Joel" Professor of Physics and Dr. Graham Hodgson. Primary F.R.C.S. courses are held twice yearly.

Scholarships and Prizes.—Two Entrance Scholarships, value £100 each, and four University Scholarships, value £100 each, are awarded annually. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship is awarded annually on the nomination of the Head-master of Epsom College. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5*s.*; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Kingston Fowler Prize, value £15; the Leopold Hudson Prize, value 11 guineas; and the Colin Mackenzie Prize, value 10 guineas. There are numerous class prizes.

The Students' Amalgamated Clubs include the following: Medical Society, Common Room Society, Musical Society, cricket, football, rowing, chess, lawn tennis, hockey, sailing, golf, fencing, and swimming. There are a restaurant and a gymnasium in the school buildings, and athletic grounds at N. Wembley. Squash rackets are also available.

St. Thomas's Hospital

This hospital consists of eight linked-up pavilions, the medical school building being separated from the hospital by a quadrangle; the school buildings comprise the department of anatomy with its lecture theatre, museums, research laboratory, and completely equipped X ray department, erected in 1935; the Sherrington School of Physiology, and a newly rebuilt department of chemistry with physical and biological laboratories. The hospital contains 644 beds and, in addition, has 30 beds at the Pyrford Orthopædic Hospital and 22 beds at the St. Thomas's Babies Hostel; there are teaching facilities for a further 150 beds, while students profit by liaison with Lambeth Hospital, where demonstrations are arranged at regular intervals and senior students attend with facilities for clinical work. There is a Clinical Unit in medicine under a whole-time director, with laboratories and reading-room attached.

A complete curriculum is provided for students, the hospital having departments for the treatment of all the specialties. Particular attention is given to antenatal instruction and the teaching of diseases of children. A tuberculosis department in the hospital forms part of the Lambeth anti-tuberculosis scheme. The V.D. department is part of the L.C.C. scheme. In each department much clinical material is available. Instruction in anæsthetics takes place during appointment as dresser. Private coaching facilities are available and classes for the Primary F.R.C.S. Eng. are held. Revision classes are held in anatomy and physiology in accordance with the medical curriculums of Oxford and Cambridge. The obstetric training of students is supplemented by an arrangement with St. James Hospital, Balham, whereby throughout the year two students at a time are in residence and take part in the maternity work. A special maternity ward of the hospital gives the student scope for elementary training before he undertakes cases in the district. In addition to the usual routine as clerk and dresser, every student works for a period of three months at the Medical Unit of the hospital. The post-mortem room, rebuilt in 1932, has a large amphitheatre adapted for teaching purposes and for the intimate study of morbid pathology.

The following appointments are open to students: A resident assistant physician and a resident assistant surgeon, salary £225 each per annum, and a resident anæsthetist, salary £200 per annum, are appointed annually. The assistants in the medical and surgical units hold appointments with a maximum tenure of four years. These officers are salaried. Three medical and four surgical registrars at a salary of £250 hold their appointments on a tenure renewable to a maximum of four years. A pathological registrar to the department of obstetrics and gynæcology (at an annual salary of £250), an ophthalmic registrar (at an annual salary of £200), and an orthopædic registrar (unpaid) are appointed yearly. Nine chief assistants (unpaid) are appointed to the special departments. Eight resident casualty officers and anæsthetists are appointed every six months. Seven house physicians (including two obstetric house physicians and one house physician to the department of diseases of children), nine house surgeons (including two ophthalmic house surgeons, one orthopædic house surgeon, and two house surgeons to the ear, nose, and throat department) are appointed every six months. Clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. There are three assistants in the department of pathology; the senior receives £600 a year, and the two juniors £450 each.

Scholarships and Prizes.—At this school there are the following Entrance Scholarships: Two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following—Anatomy, Physiology, Pathology, Chemistry; also the "Hector Mackenzie" University Exhibition of the value of £60. The value of all entrance scholarships is taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, Medicine, Pathology, and Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) Toller Prize, Medicine; (*g*) Cheselden Medal, Surgery and Anatomy; (*h*) Clutton Memorial Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship, £50, biennially, Surgery and Surgical Pathology; (*j*) Solly Medal and Prize, biennial, Reports of Cases; (*k*) Sutton Sams Prize, biennial, Report of Cases; (*l*) Bristowe Medal, Pathology and Morbid Anatomy; (*m*) Hadden Prize, Pathology and Morbid Anatomy; (*n*) Grainger Testimonial Prize, £31 10*s.*, Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; Perkins Research Fellowship, £40–£100; Myers Prize in Psychological Medicine, £10 10*s.*

In the school buildings are a reading-room and library, containing approximately 8500 volumes. There is here a selection of new editions of current text-books, and periodical literature suitable to the needs alike of students and research workers. The Shattock museum, which forms part of the buildings, contains over 5000 preparations, illustrating all morbid lesions of importance, an illustrative type series, and many specimens of historical interest. In the west wing of the school are the pathological institute and photographic department.

Opposite the hospital is St. Thomas's House, the premises of the amalgamated clubs, providing all the usual amenities and having squash courts, a miniature rifle range, and ample garage accommodation. There is a hard tennis court in the quadrangle. A hostel in the same buildings accommodates 50 resident students. All field games are provided for and there is a sports ground at Chiswick with one of the best cricket pitches in the country.

University College Hospital

Instruction in the preliminary scientific subjects is given at the College. The final subjects in the curriculum are taught at the medical school of the hospital, which has 540 beds, including 85 in the new obstetric hospital. Clinical Units in medicine, surgery, and obstetrics and gynæcology are now in operation. The whole-time directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and out-patient department of the hospital. The department of otology, rhinology, and laryngology (the Royal Ear Hospital) has been provided with a separate building in Huntley-street, adjacent to the obstetric hospital. It contains 41 beds, including eight private wards for patients of limited means. In the dental school in Great Portland-street there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

The hospital is equipped with all modern appliances for investigation. The new buildings of the obstetric hospital of 85 beds (rendered possible by the Rockefeller Benefaction), the new residents' house (with accommodation for 30 residents and students), the extension to the nurses' home, and new research laboratories for the medical school are now finished and in full occupation. Twelve women students are admitted annually.

Original research in all subjects can be pursued in the laboratories of the school under the professor of pathology, and students can receive grants under certain conditions from the Charles Graham Medical Research Fund.

Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the medical school and hospital. Sixteen house physicians, ten house surgeons, ten obstetric assistants, four house surgeons to the Royal Ear Hospital, are selected annually by examination from among the senior students who have a medical qualification. All house officers reside free in the hospital. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: resident medical officer, surgical registrar, medical registrar, obstetric registrar, Harker-Smith cancer registrar, ophthalmic registrar, registrar to the Royal Ear Hospital, radiological registrar, casualty medical officer and a casualty surgical officer, first assistant in the children's department; assistants in ear, nose and throat, ophthalmic, skin, and venereal diseases departments and in the department of psychological medicine, and house anæsthetist.

Assistants to Medical, Surgical, and Obstetric Units. These salaried appointments are for senior students who may desire to remain at Hospital after holding the ordinary resident appointments continuing clinical work or pursuing laboratory or other research. The salaries range from £250 up to £900 a year, resident quarters being provided only for the chief assistant to the Obstetric Unit. The total number of such assistantships varies from time to time, being generally about 12, and an aggregate sum of about £5000 annually is available for their salaries.

Scholarships and Prizes (those in connexion with University College have already been enumerated).—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows: (*a*) Entrance Scholarship, Bucknill, 60 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Scholarships entitling the holder to the Final Course of Medical Study, two of the following subjects: Anatomy, Physiology, General Pathology, Biochemistry; (*e*) Goldsmid Entrance Exhibition, entitling the holder to a reduction by £80 in the fees due for the full course of Final Medical Studies, two of the following subjects: Anatomy, Physiology, General Pathology, Biochemistry; (*f*) Filliter Entrance Scholarship, entitling the holder to a reduction by £52 10*s.* in the fees due for the full course of Final Medical Studies. Students need take Pathology alone if they desire to enter for he Filliter Entrance Scholarship only; (*g*) Ferriere cholarship, value £25; (*h*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*i*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*j*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*k*) Magrath Clinical Scholarship, about £160, Clinical Cases; (*l*) Percival Alleyn Scholarship, about £110, Surgery; (*m*) Filliter Exhibition, £30, Pathology; (*n*) Erichsen Prize, £21, Practical Surgery; (*o*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*p*) two Liston Gold Medals for Clinical Surgery; (*q*) Alexander Bruce Gold Medal for Pathology and Surgery; (*r*) Tuke Silver and Bronze Medals for Pathology; (*s*) Radcliffe Crocker Travelling Scholarship for Dermatology; and (*t*) Leslie Pearce Gould Travelling Scholarship for Surgery. A limited number of Bursaries are available from the Atchison Fund, awarded at the discretion of the Dean, to enable students whose means do not allow to take Resident Posts.

The Museum of Pathological Anatomy is open for study daily. The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and medical school on the recommendation of the school committee. The library, open daily to every student of the School, contains about 30,000 medical works, including all the current text-books and works of reference.

The Medical Society exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the medical school are required to become members, and meetings are held once a fortnight for appropriate discussion connected with the study of medicine. The Society includes various athletic clubs and superintends the gymnasium and squash racquet courts in the medical school, and the athletic ground at Perivale.

In Gower-street there is a well-equipped residential hostel solely for the use of the medical students.

Westminster Hospital

The Hospital contains 241 beds, and has attached to it a Radium Clinic with 22 beds, elaborately equipped for all forms of radium therapy and research. There are separate departments for diseases of the eye, skin, teeth, ear, nose and throat, for orthopædic practice, for diseases of women, for diseases of children, for radiography, for anæsthetics, for venereal disease, and for massage, electrical, and light treatment. The anatomical, pathological, and materia medica museums are open to all students of the school.

The entire teaching of the hospital is devoted to the subjects of the Final Examinations. Arrangements are made for the tuition required for Preliminary and Intermediate subjects.

Paid appointments as medical, surgical, and obstetric registrars, casualty officers, house physicians, house surgeons, and anæsthetist are available for students when they have passed their examinations.

There are excellent opportunities for research work in the recently endowed John Burford Carlill Laboratories. Grants to assist research workers are made annually from the John Burford Carlill Endowment.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £75 each. Summer Session: Two Scholarships in Anatomy and Physiology, £75 each. Four Scholarships in Chemistry, Physics, and English Essay, £75 each. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, Reports on Cases; Chadwick Clinical Surgery Prize, Reports on Cases; Chadwick Prize in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederick Bird Medal and Prize, open to fourth-year students, medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, a paper and tests in practical work; Hanbury Prize in Diseases of Children; Alfred Hughes Memorial Prize, open to second-year students, books or instruments—Anatomy; Huxley Memorial Prize, open to second-year students—Physiology; Carter Gold Medal and Prize for Botany, open to students of not more than three years' attendance, gold medal and books; Jelf Medal awarded to third-year students; Daniell Scholarship, £40, Chemistry; Rabbeth Scholarships open to first-year students; Class Examinations in the Preliminary Scientific Course. Ischley Prize in Pharmacology, open to students who within two years of passing the first examination for medical degrees have completed the course in Pharmacology. Hare Prize in Zoology, open to first-year students.

The annual fee includes membership of the Sports Union Club with its various branches—i.e., football, cricket, tennis, hockey, boxing, fencing, swimming, and Guthrie Society. The athletic grounds are situated in Tooting and are reached in 20 minutes from the hospital.

London (Royal Free Hospital) School of Medicine for Women

The Royal Free Hospital contains 315 beds. The Hospital also has large casualty and out-patient departments. A new block has recently been completed to extend the special departments for orthopædic, light, and obstetric and gynæcological out-patients. Maternity districts are attached to the Obstetric Unit operating in the Gray's Inn-road and Essex-road areas. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital, Queen-square, South London Hospital, and Central London Ophthalmic Hospital. Students after qualification can hold posts at the Royal Free Hospital of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist and pathologist, and medical, gynæcological, and surgical registrars; and the posts of demonstrators in all the departments at the Medical School.

A Clinical Unit in Obstetrics controls 68 beds. The Pathology Unit has been extended and spacious new quarters are now available.

Courses are arranged for the Primary Fellowship Examination of the College of Surgeons.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments. Students' Chambers are provided in the neighbourhood of the school and the Warden can be consulted on the subject.

Scholarships and Prizes.—Among the larger of these awards are the following: (*a*) Isabel Thorne and A. M. Bird Scholarships of £30 a year for six years; (*b*) St. Dunstan's Medical Exhibition, £60 a year for three or five years; (*c*) Mrs. George M. Smith Scholarship, £50 a year for three or five years; (*d*) Bostock Scholarship, £90 a year for five years; (*e*) Mabel Sharman-Crawford Scholarship, £20 a year for four years; (*f*) Sir Owen Roberts Scholarship, £75 a year for four years; (*g*) Fanny Butler Scholarship, £16 a year for four years; (*h*) Sarah Holborn Scholarship, £20 a year for three or five years; (*i*) Dr. Margaret Todd Scholarship, £37 a year for four years; (*j*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, £25 a year for four years; (*k*) Alfred Langton Scholarships, £35 a year for two years; (*l*) Flora Murray Bursary, awarded every year to a fifth-year student, £50; (*m*) A. M. Bird Clinical Scholarship, £30 a year for three years; (*n*) School Jubilee Bursary, £50 a year for three years; (*o*) John Byron Bursary, £20 for two years; (*p*) Helen Prideaux Prize and Julia Ann H. Cock Prize, to be spent in assisting the newly qualified holder to further study, £60 each; (*q*) A. M. Bird Post-graduate Scholarship in Pathology, £200 for one year; (*r*) Mabel Webb and A. M. Bird Research Scholarship, £200 for one year; (*s*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, open to all medical women, preferably coming from India or going to work in India. The Dorothy Chick Gift, £14, and other prizes value £84 are awarded annually. The Students' Union arranges the social, athletic, and other clubs and societies.

Inquiries may be addressed to the Warden and Secretary of the Medical School, 8, Hunter-street, London, W.C.

British Postgraduate Medical School

The school, which was opened by H.M. the King in May last, is the outcome of joint action by H.M. Government, the University of London, and the London County Council. The School is being run in connexion with the London County Council Hospital at Hammersmith, which has at present some 400 beds, a number which is likely to be increased at a later date. Parliament voted £100,000 for its new buildings and equipment, and the London County Council is spending a similar sum on additional hospital buildings and equipment in order to improve the supply of clinical materials for teaching.

The school, of which the buildings are now substantially completed, is situated in the grounds of the Hammersmith Hospital at Ducane-road. These grounds cover 14 acres and provide ample room for further building. Ducane-road runs parallel to Western-avenue, to the south of a large area of open ground known as Wormwood Scrubs, which can never be built over. On the west lies the prison, and the extensive plot on the east belonging to St. Clement Danes Grammar School will also remain open.

The Board of Governors of the Postgraduate School, as prescribed in its Charter, is made up of representatives of various interested bodies, and at present consists of 17 members under the chairmanship of Sir Austen Chamberlain. These are nominated by the Secretaries of State for Dominion Affairs, India, and the Colonies, the Ministry of Health, the London County Council, the University of London, the English Royal Colleges, the Society of Apothecaries of London, the Royal Society of Medicine, and the British Medical Association; three additional Governors are coöpted.

The school has been provisionally recognised as a school of the University of London, and all appointments of Professors and Readers are made by that body. It is open equally to men and women.

Facilities are provided for at least three different classes of post-graduate student: (1) students from the Empire and abroad who at present have scarcely any opportunity of sharing in practical work in this country; (2) those who have qualified at one or other of the British undergraduate medical schools and feel a desire for further scientific training; (3) practitioners, especially those from the country, requiring short and highly concentrated refresher courses to keep them in touch with new developments in medicine and surgery.

The new block, in which is housed the medical school, consists of three floors around a central courtyard. On the ground floor is the clinical theatre, with seating room for 100 students, directly abutting on the main east-west corridor of the hospital, with a room for a cinema operator on the one side and examination rooms for patients on the other. On the north side of this floor is a very complete morbid histology department. On the first floor are the library and museum, as well as the lecture theatre which lies over and duplicates the clinical theatre below.

The following senior appointments to the school have been made: Dean, Colonel A. H. Proctor; Professor of Medicine, Dr. F. R. Fraser; Professor of Obstetrics and Gynæcology, Dr. James Young; Professor of Pathology, Dr. E. H. Kettle; Professor of Surgery, Mr. G. Grey Turner. Visiting experts are invited to conduct special courses from time to time, and that, while ample opportunity for refresher courses is to be provided, advanced workers will find their needs considered.

The first two refresher courses were held respectively in June and July last and further courses are to be held commencing on Sept. 16th and Nov. 18th. The subjects dealt with in these courses are selected mainly from those recommended in the British Medical Association memorandum. Each subject is dealt with by a recognised authority, assisted by the staff of the school. For the specialties visits are arranged to Special Hospitals. A course for local practitioners is being organised. Lecture-demonstrations will take place weekly at convenient times throughout the winter. A course of lectures on the Place of the Laboratory in Clinical Work will be given during the winter.

Apart from the special courses, graduates who have the time available join the school for "hospital practice and tuition." Such students attend from 10 A.M. to 4 P.M. Clinics are held daily. Students have every opportunity of examining and studying cases under expert guidance, and of receiving tuition thereon. They also attend the regular conferences between the different departments and the radiological and pathological demonstrations, which are held weekly.

At the hospital a new surgical and maternity block has been provided and a large out-patient department—this last a novel feature for one of the London County Council hospitals. It is intended to arrange that patients from any of the London County Council's hospitals may be sent to Hammersmith for the purpose of diagnosis and the specialised treatment available there.

The responsibility for the care of patients will continue to rest with the Council, and while the proper duty of the school is teaching the two functions are in practice inseparable, at least with regard to the more senior posts. The school will depend for its main income on a grant from the University Grants Committee administered through London University (which has two representatives on the Governing Body), but will also receive a payment from the Council in respect of services rendered to the hospital, and, in addition, fees are charged to students attending courses.

UNIVERSITY OF DURHAM

There are two degrees in Medicine, *M.B.* and *M.D.*; two in Surgery, *M.S.* and *D.Ch.* The University also gives degrees or diplomas in *Dental Surgery, Hygiene and Public Health, and Psychiatry.* The student's course is not likely to be altered by any action of the Statutory Commissioners under the University of Durham Act.

Medical students may prepare for the pre-registration examination in chemistry and physics at Armstrong College. Students who have taken a degree in science and wish subsequently to proceed to a degree in medicine will receive the proper exemption.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Chemistry in relation to medicine. The subjects of the Second Examination are—Anatomy and Physiology. The subjects of the Third Examination are—Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Medical Jurisprudence, and Public Health. The subjects of the Fourth Examination are—Medicine, including Therapeutics, Clinical Medicine, Surgery, Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. The University requires that at least three years be spent in residence in the University. In certain cases candidates may obtain exemption from the First and Second examinations, but the later professional examinations must be passed in the University.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must have obtained the bachelor degrees of the University, and been engaged for two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the subjects of Medical Anatomy, Medical Pathology, and the Principles and Practice of Medicine. The subjects of examination for the M.S. are—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Surgery.—Candidates must be registered medical practitioners, and not less than 25 years of age, and must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery, one at least to be spent in the University. The course of study of the candidate must be submitted to the Professor of Surgery and approved by the Board of the Faculty. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology, and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Candidates must give six weeks' notice of entry for all examinations to the Secretary of Examinations, University of Durham College of Medicine. The M.D. (essay) must be sent in before April 1st.

Scholarships and Prizes.—The following are awarded: University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £40 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for Surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year. Approved applicants may obtain special grants for surgical research from the Stephen Scott Research Fund, and for research in asthma, &c., from the William Dodds Research Fund.

The following Scholarships are tenable for one year, namely: Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology, £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for B.Hy. and D.P.H. (Part I.) Examination in Bacteriology, £25; Stephen Scott Scholarships for Anatomy and Physiology, two of £50 each; Philipson Scholarships for highest marks in Final M.B., B.S. Examinations, two of £45 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325; *Hamilton Drummond Memorial* Scholarship, in aid of research in Clinical Surgery, about £50; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for Psychological Medicine, £10; Sewell Memorial Prize and Silver Medal for Clinical Pathology.

Newcastle-upon-Tyne: College of Medicine

Hospital practice and post-graduate work are carried out at the Royal Victoria Infirmary, a general hospital containing 700 beds, and there are facilities for the study of the various special subjects. Post-graduate work, as well as voluntary courses for undergraduates, can be pursued at the Newcastle General Hospital.

Practical midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3000 cases.

Psychological medicine can be studied at the Newcastle Mental Hospital, and infectious diseases at the City Hospital, under the M.O.H. of the city.

The bacteriological laboratory is adjacent to Armstrong College.

Post-graduate Instruction.—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course is held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Venereal Diseases;

Neurology; Diseases of Children; Electrotherapeutics and Radiology; special courses in Midwifery are held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the Summer Vacation. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, also at the Princess Mary Maternity Hospital for specified periods, and for clinical instruction at Newcastle General Hospital.

There is a well-furnished Students' Union for the students of the Newcastle Division of the University, and special accommodation has been provided for women students.

The clinical work is done mainly at the

Royal Victoria Infirmary

The Infirmary has over 700 beds. Clinical lectures are delivered by the physicians and surgeons weekly and ward demonstrations are given daily. Tutorial classes are given by the assistant physicians, assistant surgeons, the medical and surgical registrars, and the assistant to the gynæcological department, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the pathologist daily or as opportunity occurs. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching: ophthalmic, throat, nose, and ear, skin, and venereal disease, gynæcological, orthopædic, and electrical. The hospital building contains the following laboratories: 1. Special pathological laboratories attached to the post-mortem rooms. 2. Bacteriological laboratory in which all clinical bacteriological investigations are carried out. 3. There is in addition a clinical laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1935 opens on Oct. 1st, and the summer session of 1936 on April 21st.

Applications for detailed information should be made to the Sub-Dean, Dr. Horsley Drummond, at the hospital.

Appointments of assistants in the pathological and other special departments and of clinical clerks and dressers are made periodically. Resident appointments are also made every six months; and each year medical and surgical registrars (who also act as tutors) are appointed from candidates who have previously held resident appointments at any recognised hospital. These latter posts afford an excellent opportunity for post-graduate study, not only at the Infirmary, but also in the departments of anatomy, physiology, pathology, and bacteriology of the college.

UNIVERSITY OF BIRMINGHAM

The University of Birmingham grants the degrees of *M.B., Ch.B., M.D., Ch.M.* There is also the degree of *Ph.D.* (for *Research Study*), a degree of *M.D.*, (*State Medicine*), and a diploma in *Public Health.* The Senate may recognise courses of study and examinations at other Universities in Physics, Chemistry, Biology, and Organic Chemistry: but at least three years must be spent in attendance upon classes in the University. The final year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. Before commencing the study of Anatomy and Physiology, examinations in Chemistry and Physics and Biology must be passed (First M.B., Ch.B.), or examinations in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. Second Examination.—Part I., Organic Chemistry; Part II., Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology. Fourth Examination (at the end of the fifth year).—Forensic Medicine and Toxicology; Public Health; and Materia Medica, Pharmacology, and Therapeutics. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery and Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months. Vaccination instruction must be taken and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery. Distinctions may be awarded in the subjects (severally) of the Second, Third, Fourth, and Final; and First- and Second-Class Honours in the Final Examination.

Degrees of Doctor of Medicine and Master of Surgery. One year after having passed the final M.B., Ch.B. examination the candidate can present himself for these higher degrees. They present a thesis on some medical or surgical subject, and pass a general examination in Principles and Practice of Medicine for the M.D. and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch.M., or, at the discretion of the examiners, in a special branch of Medicine or Surgery respectively. A thesis of exceptional merit may exempt from any part of these examinations, in which Honours may be awarded.

Degree of Ph.D.—Candidates must possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and have been engaged as a rule in advanced study for two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. But under approved conditions after the first year research may be carried on elsewhere, when, on completing the course, candidates present a thesis and submit themselves for oral and possibly written examination.

Scholarships and Prizes.—The following are awarded:—Entrance Scholarships: (*a*) Frank Fletcher and Catherine Fletcher Scholarships of £100 per annum each, for five years. Two or more offered annually; open to men and women students under certain prescribed conditions as to residence, &c.; (*b*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*c*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*d*) Dental Scholarship of £46 17*s.* 6*d.*, Open Competitive Examination in subjects learned during apprenticeship; (*e*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland; (*f*) two Ingleby Scholarships of £10 each, awarded to the candidates at Final Examination obtaining highest marks in the subjects of Midwifery and Diseases of Women; (*g*), (*h*), (*i*), and (*j*) four Queen's Scholarships of £10 10s. each, awarded to the candidate taking the first place in the Second, Third, Fourth, and Final Examinations respectively, provided that the candidate's work is sufficiently distinguished; (*k*) Priestley Smith Prize in Ophthalmology, value about £6 10*s.*, is awarded annually to the student passing the Final M.B., Ch.B. Examination on first entry who shows the best knowledge of Ophthalmology, provided the Examiners deem him worthy of this distinction; (*l*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*m*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate taking the highest place in Clinical Medicine and passing the Final M.B., Ch.B. Examination in June; the "Sampson Gamgee Memorial Medal" (Gold Medal for Surgery) is awarded annually to the best candidates passing Final M.B., Ch.B. Examination in June in Surgery (paper, oral, and clinical); the Leith-Neumann Prizes for Pathology, £10 (Medical) and £5 (Dental), are offered annually on the year's work and examinations; Peter Thompson Prize for Anatomy (Third Year); Bertram Windle Prize for Special Work in Anatomy (value about £9); and John Barritt Melson Gold Medal for Physiology (Third Year). The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years. open to all students.

Post-graduate Instruction.—A "William Withering Lectureship" has been established. Courses of lectures are given annually for post-graduates on subjects chosen from year to year (no fee). Post-graduate courses of clinical demonstrations for general practitioners are arranged annually by the University Clinical Board (April to July) at the Birmingham United Hospital (General and Queen's) and the Children's Hospital.

The students receive clinical instruction by attending the amalgamated practice of the General Hospital, Queen's Hospital, Maternity Hospital, Children's Hospital, Birmingham and Midland Eye Hospital, Mental Hospital, and Fevers Hospital, under the direction of the University Clinical Board. Appointments are open to students varying from £40 to £200 a year.

Queen's Hospital

There are 333 beds. Ward rounds and out-patient clinic classes are held daily, and regular tutorial classes throughout the session. *Post-graduate* courses arranged by the University are conducted every year. There are special departments in gynæcology, diseases of the eye, of the ear, nose, and throat, dentistry, dermatology, radiology, pathology, bacteriology, iochemistry, physiotherapy, electrocardiography, nd there is a psychiatric clinic associated officially with the Birmingham Mental Hospitals. There are also large wards for midwifery and postnatal cases, a nursery for instruction in infant welfare, an extensive midwifery distric[illegible] and residential facilities for students. There a[illegible] 29 resident appointments (inclusive of regist[illegible]) available each year for recently qualified st[illegible]ts.

Birmingham Gen[illegible]spital

There are 487 bed[illegible] [illegible]ecial wards for children, gynæcological, ear an[illegible] [illegible]oat, venereal, and radium cases; special beds f[illegible] [illegible] and skin cases. Laboratories for bacteriology, [illegible]emistry, cancer research, and morbid histology. [illegible]arate rooms adjoin the medical and surgical [illegible] for clinical pathology. Six operating theatres ([illegible] out-patients and one for casualty department) the[illegible]h is a separate department), are all of them [illegible] on modern lines. In addition to clinical teac[illegible]iven in the wards and out-patient department b[illegible] the [illegible]onorary staff, medical and surgical tutorial clas[illegible], a[illegible] held for senior and junior students. Clinical [illegible] in all the special departments, which includ[illegible] [illegible] for radium, electrotherapy, electrocardiogra[illegible] investigation, and venereal diseases. Post-gr[illegible] classes are held in every branch of medicine a[illegible] [illegible]gery. The Jaffray Branch Hospital contains 6[illegible]

UNIVERSITY OF LIVERPOOL

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (*M.B.* and *Ch.B.*), Doctor of Medicine (*M.D.*), Doctor in Philosophy (*Ph.D.*), Master of Surgery (*Ch.M.*), and Master of Orthopædic Surgery (*M.Ch.Orth.*). There is a diploma in *Medical Radiology and Electrology*.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least three of the six years of medical study must have been passed in the University, at least two of which must have been passed in the University subsequent to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The subjects of the First Examination are: (1) Chemistry; (2) Biology (Zoology and Botany); (3) Physics. The subjects of the Second Examination are: (1) Anatomy; (2) Physiology (including Biochemistry and Histology). The subjects for the Final Examination are: (I) (*a*) Pathology, (*b*) Pharmacology and General Therapeutics; (II) (*a*) Forensic Medicine and Toxicology, (*b*) Public Health; (III) (*a*) Obstetrics and Gynæcology, (*b*) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology, (*c*) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children. Candidates may take Parts (I), (II), and (III) separately, provided that they do not present themselves for Part (III) until they have completed the sixth year of medical study and have passed the examination in Parts (I and II).

Degrees of Doctor of Medicine and Master of Surgery. No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has received the Degrees of Bachelor of Medicine and Bachelor of Surgery (Liverpool), and at least two years have elapsed since he passed the examinations for those degrees. A candidate may also take the degree of Doctor of Medicine by examination after five years from taking Liverpool M.B., Ch.B. in (*a*) Medicine, together with (*b*) a selected branch of Medicine. A candidate for the degree of Doctor of Medicine, who elects to present a thesis, is required (*a*) to present a thesis, acceptable to the Faculty, and certified to be the candidate's own work, together with (if the candidate desires) copies of published original papers upon Medical Science; (*b*) to present himself for an oral examination on the subject of the thesis.

The subjects of examination for the Degree of Master of Surgery are: Surgery, Clinical Surgery, Operative Surgery, Surgical Pathology and Bacteriology, and Surgical Anatomy.

Degree of Master of Orthopædic Surgery.—May be conferred on graduates in Medicine of Liverpool or other approved University and graduates of a Faculty other than Medicine of Liverpool or other approved University who are Fellows of the Royal College of Surgeons of England, Edinburgh, or Ireland, or of the American College of Physicians.

The University also awards Diplomas in Medical Radiology and Electrology, Public Health, Tropical Medicine, and Tropical Hygiene.

Scholarships, Fellowships, and Prizes.—The following are awarded: (*a*) Robert Gee Entrance Scholarship (Men), annually, of £42 10*s.*, tenable for four years; (*b*) Junior Lyon Jones Scholarship, of £10 *per annum*, tenable for two years, on results of First M.B. Examination; (*c*) Senior Lyon Jones Scholarship, of £19, Competitive Examination on results of Professional Examination in Anatomy and Physiology; (*d*) Derby Exhibition of £15, Competitive Examination in Clinical Surgery; and (*e*) Clinical School Exhibition of £15 in Clinical Medicine; (*f*) University Scholarship of £50 for one year, awarded on results of the Final (Part I.) Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £150 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Biochemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (*m*) Ethel Boyce Fellowship in Gynæcology, of £100, for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October in the year of the award; (*o*) Rankin Exhibition in Practical Anatomy, of £23, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £27; (*r*) Ridgway Research Scholarship (£94); (*s*) T. J. Hughes Research Scholarship (£72); numerous prizes and medals.

The Medical School.—All the laboratories and classrooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Medicine; and the Thompson-Yates Laboratories for Physiology and Pathology. There is also a separate building for Tropical Medicine and Public Health. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation.

Clinical Studies.—The Clinical School of the University consists of four general hospitals—the Liverpool Royal Infirmary, the David Lewis Northern Hospital, the Liverpool Royal Southern Hospital, and the Liverpool Stanley Hospital; and of five special hospitals—the Eye, Ear, and Throat Infirmary, the Women's Hospital, Liverpool, Liverpool Maternity Hospital, the Royal Liverpool Children's Hospital, and St. Paul's Eye Hospital. These hospitals contain in all a total of about 1500 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with an extensive field for clinical education and study. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF MANCHESTER

Four degrees in Medicine and Surgery are conferred by the Victoria University of Manchester—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine, a Diploma in Public Health, a Diploma in Bacteriology, and a Diploma in Pathology are awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degrees of M.B. and Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination.

The First Examination: (1) Chemistry and Physics; (2) (*a*) Botany, (*b*) Zoology. Candidates must have attended the prescribed courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Inorganic and Elementary Organic Chemistry and Physics; Part 2, (*a*) Botany, (*b*) Zoology. The candidates sit for these parts separately. The Second Examination: (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. Both parts must be passed simultaneously. The Third Examination: (1) Pharmacology and Materia Medica; (2) Pathology and Bacteriology. The Final Examination: (1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine; (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts: Part I., Forensic Medicine, Hygiene and Preventive Medicine; Part II., Medicine, Surgery, Obstetrics and Gynæcology (Systematic, Clinical, and Oral). The two parts of the Final Examination must each be passed as a whole. Candidates for the Second Part must have completed the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery of this University, and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation, or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery of this University, and at least one year had elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Degrees of B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in Medicine who in their third year of study for the degree of M.B., Ch.B., complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology, who are students in Medicine, are required to attend courses in advanced Anatomy and Physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science may proceed to the degree of M.Sc. by presentation of an approved thesis.

Diplomas: 1. The following are available for candidates holding a registrable qualification in medicine, surgery, and midwifery; examinations are in two parts in each diploma and are written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination.

(*a*) *Diploma in Psychological Medicine.*—Part time course: extending over three University terms, two of which must be spent at the University. Six months' residence must be spent at a recognised Hospital for Mental Diseases.

(*b*) *Diploma in Public Health.*—The course extends over twelve calendar months at least: Part I. of the examination is held in June and October, and Part II. in March and October. Instruction for at least one of the parts must be taken out at the University.

2. *In Veterinary State Medicine.*—Length of course, three University terms. Candidates must be members of the Royal College of Veterinary Surgeons.

3. *In Bacteriology.*—For candidates who have graduated either in science or medicine, or obtained other approved qualification. Length of course, one academic year. A satisfactory thesis on an approved subject must be presented.

4. *In Pathology.*—For candidates who have obtained a registrable medical qualification or other qualification approved by the Senate. Length of course, one academic year. A satisfactory thesis on an approved subject must be presented.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women; Graduate Entrance (fees up to 160 guineas); two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Dickenson Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100; Holt Post-Graduate Medical Scholarship for Women, £60; Elected Research Studentships. Fellowships: Leech Research, £70; Professor Tom Jones, Surgical, £105; Morrison Watson in Anatomy, £150; John Henry Agnew in Diseases of Children, £120; Delépine in Preventive Medicine (biennial), £300; Pilkington Fellowship in Cancer Research, £300; Knight Fellowship in Psychological Medicine; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology—Junior £10, Senior £20; Wild Prize in Pharmacology, £10; Turner Medical, two prizes each of 10 guineas; Dumville Surgical, £15; John Henry Agnew in Diseases of Children, £30. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories (now removed to special buildings close to the Royal Infirmary) ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped as part of a new department for investigation in cancer. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica; new Pharmacological Laboratories were recently added. In the public health department, which is lodged in a separate institute in York-place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the medical school of the University and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, mental hospitals, a convalescent home, and other special hospitals.

A residential Hostel for final year students has been opened in proximity to the University and the Royal Infirmary, where accommodation is available also for a few graduates.

The Manchester Royal Infirmary, near the University, has accommodation for 640 beds (including 54 beds at the Central Branch). Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds; and (2) the Central Branch in the City, which has accommodation for 54 patients. The Associated Hospitals thus contain 776 beds and are under the same management. The medical side consists of four units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached. One of the surgical units is assigned to orthopædic and neurosurgical cases. The gynæcological, aural, and out-patient departments each have their own operating theatre. Bacteriological investigations are carried out in a special clinical laboratory. A department for the study of heart disease, with an electric cardiograph and other instruments for research, diagnosis, and teaching purposes is attached to the medical wards. There is also a laboratory for clinical research. The X ray department has nine separate X ray outfits for different purposes, and one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department. Women students are admitted on the same terms as men. Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. All the usual appointments may be held by those who have attended the practice of the Infirmary.

The Royal Manchester Children's Hospital at Pendlebury contains 190 beds and 30 in the Convalescent Home, Lytham St. Anne's. Clinical instruction is given by the medical staff at the Hospital and Dispensary, Gartside-street, Manchester. There is a massage and electrotherapeutic department, also an artificial sunlight department. Clinical assistants are appointed for periods of six months. There is an orthopædic department, out-patients for which are seen at Gartside-street, and a ward at Pendlebury is devoted to those cases needing operative treatment.

Ancoats Hospital, Manchester, is a general hospital of 150 beds and a Convalescent branch which is situated at Great Warford, Alderley Edge, Cheshire, and has 35 beds.

The medical side consists of three units under the care of three honorary physicians with three out-patient clinics of consultative nature. A cardiographic department is under the care of one of the physicians. Much work is done in gastro-enterology, neurology, and diseases of the blood. The surgical units are four in number, each under the care of an honorary surgeon; the orthopædic department, which deals with all fractures and bone injuries, is very large. One surgical unit is devoted to abdominal surgery, and one is devoted to oto-rhino-laryngology, while a urological department is under the care of one of the honorary surgeons. All these units have a largely attended out-patient department. Clinical teaching is given both to under-graduate and post-graduate Students in all the out-patient clinics which are free to them, and in the wards, while special courses of post-graduate lectures are given as part of the Manchester University post-graduate scheme. Clinical assistantships are available for post-graduates.

There are six resident appointments which are open to men and women graduates. There are also four registrar appointments, part-time: medical, surgical, orthopædic, and laryngological made annually.

UNIVERSITY OF LEEDS

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine. Courses and Degrees in the Faculty are open to men and women alike.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination. The First Examination consists of: Part I., Physics and Inorganic Chemistry; Part II., Organic and Physical Chemistry; Part III., Botany; Part IV., Zoology. Candidates will be allowed to pass the parts separately. The Second Examination consists of: Part I., Materia Medica and Practical Pharmacy; Part II., Anatomy and Physiology. Candidates will be allowed to pass either part separately. The Final Examination consists of: Part I., Pharmacology, Pathology, and Bacteriology; Part II., Medicine, Surgery, Obstetrics and Gynæcology; Part III., Forensic Medicine, Public Health, and Therapeutics. Part I. may be taken at the end of the second clinical year, and Parts II. and III. may be taken at the end of the third clinical year, but not before the completion of the fifth year of medical study. If taken separately Part III. may not be passed before Part II.

Degree of Doctor of Medicine and Master of Surgery. Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least two years' Hospital Practice or four years' other professional practice for the former and one year has elapsed for the latter since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine may present a dissertation and, if the dissertation is considered to be of exceptional merit, will not be required to pass an examination. The first term commences on Oct. 1st. Prospectus can be obtained from the Academic Sub-Dean.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods, or post-graduate classes held by members of the clinical staff, may do so on application to the Clinical Sub-Dean, from whom particulars may be obtained.

The Scholarships and Prizes, in order of importance, are: (1) medical scholarship, value £130; (2) Infirmary scholarship, value £75; (3) the Littlewood prize, value about £50; (4) West Riding Panel Practitioners' prize, value £25; and (5) the William Hey gold medal. The last is generally awarded to a young graduate who figures in the other prizes and sentimentally may be considered of first importance.

Clinical Studies.—The clinical studies are pursued mainly at the **LEEDS GENERAL INFIRMARY AND WOMEN'S HOSPITAL**, which has accommodation for 694 in-patients, including 88 beds at branch hospitals in the country. Clinical teaching takes place daily in the wards, in medicine and surgery. There are medical, surgical, ophthalmic, aural, electrotherapeutic, and radiographic departments, in each of which special instruction is imparted to students. Gynæcological and children's departments, together with laryngeal, venereal, and skin clinics, are in operation, and there is a special ward for cases of nutritional disorders of children.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

The General Infirmary.—This hospital has accommodation for 655 beds which are allotted, 477 to general medical and surgical cases, adults and children, the remainder being given up to ophthalmic, aural, orthopædic, radium, and dermatological cases. In that total is included the patients in the semi-convalescent branch hospitals, the Ida and Robert Arthington, containing 100 beds. The University and hospital paid appointments in connexion with the Infirmary and other bodies are numerous. Associated also with the Infirmary is the Women's Hospital of 84 beds for the treatment of gynæcological and obstetric diseases; students when eligible attend the practice of this hospital, to which there are two paid resident appointments.

Leeds Maternity Hospital contains 135 beds for cases of labour, while there is other accommodation attached for the treatment of morbid pregnancies. There is an X ray department, and large extern districts are centred upon the institution. The hospital is affiliated to the University for purposes of clinical training, and every student takes an obstetric clerkship and attends in the intern and extern departments. During the second and third months personal contact with not less than 20 cases of labour is required, the students being resident in the neighbouring hostel.

West Riding Mental Hospital.—The well-known hospital at Wakefield accommodates 2600 patients, a separate building, containing 360 beds, being provided for the treatment of acute insanity, while mentally deficient children are accommodated in separate homes in juxtaposition. Clinical clerkships in the wards and laboratories can be filled by qualified practitioners or, on application to the medical superintendent, by senior students. This hospital is a recognised institution for the purpose of training for the Diploma in Psychological Medicine. Courses of Lectures in Mental Diseases and laboratory work can be taken at the hospital, forming part of the University of Leeds Course for the Diploma.

UNIVERSITY OF SHEFFIELD

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation, and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequently to the date of his matriculation, three of such years at least having been passed in the Faculty of Medicine of the University one at least being subsequent to the passing of the Second Examination. The subjects of the First Examination are Chemistry, Physics, and Biology. Candidates must, in addition to matriculation, pass a preliminary examination in Physics and Chemistry before taking the First Examination. Students who before entry have attained a standard in Chemistry and Physics approved by the Faculty of Medicine have the opportunity of working for the degree of B.Sc. (with honours) in Physiology concurrently with their work for the degree of M.B., Ch.B. The Second Examination: Candidates must have attended courses of instruction in Physiology (first part) for one year, and in Anatomy for five terms. The Third Examination: Candidates must have attended courses of instruction in Pathology for five terms, in Pharmacology for four terms (and one term in Pharmacy), in Applied Anatomy for four terms, and in Physiology (second part) for six terms. The Final Examination: The subjects are, Part I., Forensic Medicine and Public Health. Candidates must have attended courses *for one term in each subject*; *Part II.*, Medicine (including Mental Diseases, Diseases of Children, and Vaccination), Special Pathology (including Morbid Anatomy and Clinical Pathology), and Therapeutics; Part III., *Surgery (including the* administration of Anæsthetics, Diseases of the Ear, Nose, and Throat, Ophthalmology, and Surgical Pathology), and Obstetrics and Gynæcology, including Antenatal and Postnatal practice and Infant Hygiene. Candidates for Parts II. and III. must have completed a minimum of five and a half years of approved study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least three years previously, and must since have held for not less than twelve months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology and Bacteriology.

Scholarships and Prizes.—The following scholarships are offered: Four Town Trustees scholarships offered annually, each of the value of £50 per annum for three years. Medical: offered annually, covers cost of tuition for a degree course in the Faculty of Medicine. Six Edgar Allen, offered annually, each of the value of £100 per annum for three years. Post-graduate: Frederick Clifford scholarship, value £50 per annum, tenable for two years. Mechanics' Institute scholarship, value £50 for one year with free admission to those University courses taken by the holder in connexion with his work, renewable for a second year. Town Trustees fellowship, value £75 for one year. Medals and Prizes: Kaye scholarship; Thomas Woodcock Prize; Gold Medal in Clinical Medicine and Surgery; John Hall Gold Medal in Pathology; Holroyd Gold Medal in Anæsthetics; the Walter S. Kay Gold Medal in Mental Diseases; bronze medals. Particulars of all the above may be obtained from the Registrar.

The Medical School.—The Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain meals and refreshments at moderate prices. The University journal *The Arrows* and a Medical School journal the *North Wing*, edited by a committee of staff and students, are published each term. A well-equipped Union building is in course of erection. There is good hostel accommodation for women students and similar amenities will soon be provided for men.

Clinical Studies.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes, and, as will be seen, the aggregate number of beds is very large.

The Sheffield Royal Infirmary (500 beds) and the Sheffield Royal Hospital (340 beds) provide all the opportunities associated with a large general hospital with the usual out-patient and in-patient departments for diseases of ear, throat, and nose, eye, skin, and venereal diseases; there are also orthopædic and psychiatry clinics. The two institutions are amalgamated for the purposes of clinical practice, medical, surgical, and special, and house appointments are available. The Jessop Hospital for Diseases of Women, with 143 beds, has also a maternity department, with about 110 in-patients per annum and about 3000 out-patient cases attended; in addition there are facilities for obstetrical work at the Municipal Hospital. The Children's Hospital has 118 beds. Special courses on acute Infectious Diseases are held at the City Fever Hospital (740 beds) and on Tuberculosis at the Municipal Sanatoria and Clinics (510 beds). The South Yorkshire Mental Hospital (2000 beds) is available for teaching in Mental Diseases. Every facility is afforded in the various laboratories for the prosecution of advanced study and research.

Post-graduate courses of clinical instruction are held annually in the various hospitals connected with the school.

UNIVERSITY OF BRISTOL

In the Faculty of Medicine there are the following degrees: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.),* *Diploma in Dental Surgery* (L.D.S.), and Diploma in Veterinary State Medicine.*

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass, at *Matriculation standard*, an examination called the *School Certificate* Examination, or to pass such examination as may be regarded as equivalent by the Senate. *All courses*, degrees, and diplomas are open to men and women.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics and entering on the professional curriculum at the University, or an institution recognised as equivalent, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B. are required to satisfy the examiners *in the several subjects of three examinations.* The First Examination: The subjects of examination are: Chemistry (Inorganic), Physics, and Biology. This part of the curriculum *shall extend* over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.) The Second Examination: The subjects of examination are: Organic Chemistry (Section I.) and Anatomy and Physiology (Section II.). The *Final Examination*: The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Pharmacotherapeutics, General Pathology and Bacteriology (Section I.); Special Pathology, Forensic Medicine and Toxicology, Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative, including Ophthalmology and *Oto-rhino-laryngology*), Medicine (Systematic, Cinical, and Practical, including Mental Diseases) (Section II.). The subjects included in Section II. may be taken in two *groups*—viz., Group

---

* At present in abeyance.

I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine and Toxicology. Candidates may pass Sections I. and II. together, or separately, and the two groups of Section II. may be taken together or separately. but no student can obtain honours who elects to take the two groups of Section II. separately.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a Diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—The degree may be taken in General Surgery or in Special Subjects. Candidates shall be Bachelors of the University who have practised for two years in an approved hospital (including the holding of an approved appointment for six months) and one of the two years shall have been spent in a hospital with a medical school attached. They shall present a Dissertation and pass an examination. For General Surgery, the examination shall include a written examination in Surgery, a written examination in Surgical Anatomy and Surgical Pathology, a Clinical examination, an oral examination and an examination in Operative Surgery. For special subjects—that is, Ophthalmology or Oto-rhino-laryngology or Gynæcology—the examination shall include a written examination in the Anatomy, Physiology, and Pathology of the region of the body concerned (including in the case of Ophthalmology, Physiological Optics) and a written examination in General Surgery together with a written. oral, and clinical examination in the particular branch of Surgery concerned, as well as an examination in Operative Surgery of the region concerned.

Scholarships and Prizes.—The following are awarded: The Ashworth Hallett Scholarship, value £40. open to women only; two Martyn Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value £7 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth or sixth year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in obstetrics and gynæcology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12 for dressers; the H.M. Clarke Scholarship, value £15. for proficiency in surgery; The Royal Infirmary Faculty Prize, value £20, for general proficiency; the Sanders Scholarship, value £22 10*s*., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat or skin, value £17; Lady Haberfield Scholarship, value about 25 guineas; the Paul Bush Gold Medal in alternate years to best Resident Medical Officer at Royal Infirmary; Markham Skerritt Memorial Prize, awarded every three years to that member of University, not a member of Medical Board, who, in opinion of that Board, has published the best original work during the three years.

Bristol City Senior Scholarships and those offered by the Counties of Gloucestershire, Somerset, Wilts, and Dorset and the City of Bath are tenable in the University. There are also a Miriam Badock Scholarship of the value of £120, H. H. Wills Science Scholarships, open to boys proceeding from Clifton College; and the Harold Greenwood Memorial Scholarship, of the value of £20, open to boys who have received instruction at State-provided schools in Clevedon (or elsewhere in Somerset) and subsequently at secondary schools in Somerset or Bristol. The Beaverbrook Fellowship and some of the Fellowships awarded by the Colston Research Society for research in the University are allotted to the Faculty of Medicine. University Graduate Scholarships are open to graduates of not more than one year's standing. The Michael Hiatt Baker Scholarship of the value of £200 is open to graduates from New Zealand for research in the University.

Clinical Studies.—The Allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them more than 700 beds and extensive out-patient departments, special clinics for Diseases of Women and Children, including antenatal and postnatal work, also for eye, ear, nose, and throat, and skin diseases, heart diseases, rheumatism, asthma, and cancer. Here are in addition large and well-equipped departments for Dental work and large outdoor Maternity Departments. The venereal diseases clinic for Bristol is at the Royal Infirmary. The Bristol Royal Infirmary has been selected by the National Radium Commission as a Radium Centre.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and biochemistry, in which special instruction is given in these subjects. Departments are provided and well-equipped for radiology, radiotherapy, actinotherapy, electrotherapy, and massage, with all forms of physiotherapy.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 120 beds, and that of the Bristol Eye Hospital with 40 beds, the Bristol Mental Hospital, Southmead Hospital, and Ham Green Fever Hospital. Other institutions, including Stoke Park Colony for mental defectives and the Winford Orthopædic Hospital, are also available for their special purposes.

There are numerous salaried junior appointments for residents who are graduates.

Post-graduate Study.—Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Demonstration courses are held at various times when applied for by groups of practitioners.

All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Department of Medicine, University of Bristol, who can be seen on any day by appointment.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES

THE WELSH NATIONAL SCHOOL OF MEDICINE

The University grants degrees in Medicine and Surgery—Bachelor in Medicine and Bachelor in Surgery (M.B., B.Ch.). Doctor in Medicine (M.D.), and Master in Surgery (M.Ch.)—and Diplomas in Public Health (D.P.H.) and Tuberculous Diseases (T.D.D.).

Degrees of Bachelor in Medicine and Bachelor in Surgery.—Candidates are required to pursue a course of study of not less than six academic years subsequent to their matriculation in the University, and of these years at least three must have been passed in one of the four constituent colleges situated at Aberystwyth, Bangor, Cardiff, and Swansea. They must hold an arts or science degree of the University of Wales, or of some other University approved for the purpose, but certain of the courses pursued for a B.Sc. or a B.A. degree may be counted as required for the Medical degrees.

The courses for the M.B., B.Ch. are divided into two sections. The first includes the preliminary subjects: (a) Physics, Chemistry, Botany, and Zoology; and (b) Organic Chemistry, Human Anatomy, and Physiology. Study of the preliminary subjects and of Organic Chemistry must extend over at least one academic year; study of Physiology and Human Anatomy must extend over at least two academic years; the first section of the course must occupy not less than three years. The second section includes courses in Materia Medica and Pharmacology, Pathology and Bacteriology, Hygiene and Forensic Medicine, Medicine, Surgery, and Obstetrics and Gynæcology. These courses cannot be commenced until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held twice each year.

Degree of Doctor of Medicine.—Every candidate for the degree of Doctor in Medicine shall satisfy the examiners in an examination in Clinical Medicine and shall submit a thesis to the judgment of the University. A candidate may present himself for the examination in clinical medicine during or subsequently to the second year after qualification for the degrees of Baccalaureus in Medicina and Baccalaureus in Chirurgia, and may submit his thesis during or subsequently to the third year after qualification for those degrees. The thesis shall embody the results of the candidate's personal observation or original research in some branch of medical knowledge or of some science directly relative to medicine, excepting a subject that is exclusively surgical. The candidate shall indicate in what respects his thesis appears to him to advance medical knowledge or practice. A candidate shall be required to submit himself to an oral or other examination on the subject matter of the thesis; provided always that in exceptional circumstances it shall be within the discretion of the University to exempt a candidate from such an examination.

Degree of Master of Surgery.—Every candidate for the degree of Magister in Chirurgia shall satisfy the examiners in an examination in Surgery and shall submit a thesis to the judgment of the University. A candidate may present himself for the examination in Surgery during or subsequently to the second year after qualification for the degrees of Baccalaureus in Medicina and Baccalaureus in Chirurgia, and may submit his thesis during or subsequently to the third year after qualification for those degrees. The examination in Surgery shall consist of two parts: Part I.—(i) Surgical Anatomy, (ii) Bacteriology and Surgical Pathology; Part II.—(i) Surgery, (ii) Clinical Surgery, (iii) Operative Surgery. No candidate shall be deemed to have passed in Part II. unless he has atisfied the examiners in Part I. of the examination. The thesis shall embody the results of the candidate's personal observation or original research in some branch of surgical knowledge or of some science directly relative to surgery. The candidate shall indicate in what respects his thesis appears to him to advance surgical knowledge or practice. A candidate shall be required to submit himself to an oral or other examination on the subject matter of his thesis; provided always that in exceptional circumstances it shall be within the discretion of the University to exempt a candidate from such examination.

Post-graduate Study.—Certain courses of Post-graduate study are given during the year, and facilities may be offered to graduates in medicine and other duly qualified persons to carry out research work in the different departments of the Medical School. Research scholarships are available ranging in value from £150 to £250 per annum. Further information regarding these is given later under the heading "Research Scholarships."

Clinical Institutions.—Clinical teaching is carried out in the Cardiff Royal Infirmary (490 beds); the Llandough Hospital (City of Cardiff) (340 beds); the City Lodge Hospital (City of Cardiff) (420 beds); the Cardiff City Mental Hospital (790 beds); the Cardiff City Isolation Hospital (270 beds); the Prince of Wales' Hospital (Orthopædic) (132 beds); the Cefn Mably and Glan Ely Hospitals (Tuberculosis) (298 beds). These Institutions are modern and well-equipped, and provide facilities for both In-patient and Out-patient Clinical Instruction. The Cardiff Royal Infirmary is the main teaching hospital. It serves a district having a population of more than half a million, and during the year 1934 6616 patients were admitted to the wards, and 39,681 patients treated in the Out-patient Departments.

Scholarships, Free Studentships, Prizes, and Medals. Entrance Scholarships, County Free Studentships and Scholarships are available. Particulars of these are contained in a special Prospectus, which can be obtained on application. An Isaac Roberts Scholarship in Science, of the value of £50 per annum, tenable for three years, is awarded triennially on the results of the Entrance Scholarship Examination of the Cardiff College. The Samuel Brothers' Scholarship, value £12 to £15, is awarded annually on the results of the work of the first year of the Medical Course at Cardiff College. The Dr. Price Prize, value £50, is awarded annually on the results of the work of the first year of the Medical Course at the Cardiff College. The Dr. Howell Rees Scholarship, value £17 10s., is awarded triennially, and is held in The Welsh National School of Medicine; it is awarded on the result of the examinations in Anatomy and Physiology. Numerous other prizes are awarded for proficiency in different subjects.

Research Scholarships.—A Catherine Buckton Scholarship of £60 for one year is offered periodically by the Council of Aberdare Hall (one of the Halls of Residence for Women Students) to a woman who shall undertake to do Post-graduate work. The Mrs. John Nixon Research Scholarship of £150 per annum is available for the promotion of research in Medicine and Medical Pathology. The Lord Merthyr Research Scholarship, value £200 per annum, is available for the promotion of research in Cancer. A Cecil Prosser Research Scholarship, value £250 per annum, is available for the promotion of research in Tuberculosis. The Ewen Maclean Research Scholarship, value £150 per annum, is available for the promotion of research into the factors which constitute and the conditions which vary resistance to disease, especially as regards midwifery.

Regulations regarding the diplomas in Public Health and Tuberculosis are detailed elsewhere.

All inquiries should be addressed to the Secretary, Welsh National School of Medicine, The Parade, Cardiff.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS

CONJOINT EXAMINING BOARD

All the schools described under the heading of the Universities to which they are attached are recognised as suitable places of instruction by the corporations granting medical diplomas. On p. 480 will be found the Metropolitan Hospitals, where general and special studies can be pursued. On p. 494 the centres outside London affording educational facilities are described. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Students of the Royal Colleges pass a Preliminary Examination in General Education recognised by the Board, and a *Pre-Medical Examination* in Chemistry, Physics, and Elementary Biology conducted by the Conjoint Examining Board before commencing the *five years curriculum of professional study or some* other examination recognised by the Board—namely the examination in Chemistry, Physics, and Biology for the degree in Medicine of any University recognised by the Board; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. No study of anatomy and physiology is recognised before this examination is passed. Not more than two terms of professional study (Anatomy and Physiology) will be recognised before Elementary Biology is passed. He will be admitted to the examination on producing evidence of having passed the required preliminary Examination in General Education. The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months.

There are two Professional examinations called the *First* and *Final Examinations*. The courses of study for these examinations may be commenced before the Pre-Medical examination in Biology or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology; (*b*) Physiology, including Biochemistry. Section II. Pharmacology and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including Biochemistry during five terms, courses of instruction in Pharmacology and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination, provided that the courses for Section I. have been completed. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology) and Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine, and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. Members of recognised universities outside the British Possessions are admissible to the examinations of the diplomas of L.R.C.P. and M.R.C.S. under special conditions. Graduates in medicine and surgery are required to pass the first examination and to complete 36 months hospital practice before admission to any part of the final examination. Undergraduates are required to complete the full curriculum, after passing the Pre-Medical Examination. For further information see the current regulations of the Conjoint Examination Board in England.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First Examination may present themselves for the Final Examination under special conditions. The Royal Colleges also grant Diplomas (see p. 529 in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, in Laryngology and Otology, in Medical Radiology, in Anæsthetics, and in Child Health. The Diploma in Gynæcology and Obstetrics is being discontinued after the October examination has been held. For all these diplomas candidates must hold a medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University.

Particulars may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, London, W.C.1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

THE MEMBERSHIP AND FELLOWSHIP

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of the College is designed to enable men who have just finished house appointments to sit for an examination for which their recent clinical experience has exactly fitted them. The candidate must either have obtained the licence of the College, or a degree of Doctor or Bachelor of Medicine at a University which is registrable by the General Medical Council and is recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the Registrar at the College.

Fellowship.—Fellows are selected annually from the ranks of Members by the Council of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE FELLOWSHIP

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the Primary Examination and the Final Examination. The subjects of the Primary Examination are Anatomy and Physiology and those of the Final Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly viva voce, and include the examination of patients and the performance of operations on the dead body. The Primary Examination is held in May and November and the Final Examination in May and November.

Conditions of Admission to the Primary Examination.—A member of the College is admissible to the Primary Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First Professional Examinations of the English Conjoint Board in Anatomy and Physiology, or the equivalent examination in his University, on the production of certificates of attendance upon prescribed courses.

Conditions of admission to the Final Examination.

(A) *For members of the College or Graduates in Medicine who passed the Primary Examination before Jan. 1st,* 1935.—(1) A Member of the College is admissible to the Final Examination at any time after having passed the Primary Examination, on producing satisfactory evidence of having been engaged for not less than six years in the study (or study and practice) of the profession. (2) A candidate who is not a Member of the College, but who possesses a qualification recognised by the Council for the purpose, is admissible to the Final Examination, after having passed the Primary Examination, on the production of evidence of having been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance upon the surgical practice of a recognised Hospital or Infirmary.

(B) *For all other candidates.*—A candidate who has passed the Primary Examination and who is *either* (*a*) a Member of the College who can produce satisfactory evidence of having been engaged in the study (or study and practice) of the profession for not less than six years, *or* (*b*) a Graduate of four years' standing in Medicine and Surgery in a University recognised by the Council for the purpose, is admissible to the Final Examination on producing evidence that he has held for not less than six consecutive months the post of Resident House Surgeon, or other responsible post in charge of general surgical patients in the wards of a general hospital recognised by the Council for the purpose.

Note.—In compliance with a condition of the Charter the Diploma of Fellow is not conferred upon successful Candidates until they have attained the age of twenty-five years.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS

The College was incorporated in September, 1929, "to encourage the study and practice of Obstetrics and Gynæcology, subjects which should be inseparably interwoven." It consists of Fellows and Members, and includes practically every teacher of obstetrics and gynæcology in Great Britain and the British Dominions.

Candidates for the Membership must be entered on the British Medical Register or be eligible for entry hereon. Before being accepted for the examination hey must produce evidence, satisfactory to the examination committee, of having held resident hospital appointments in general medicine or surgery and in obstetrics and gynæcology for the period laid down in the regulations (at present six months each). The examination consists of the presentation of case records and commentaries, together with an oral and clinical examination.

The Fellowship of the College is granted to those members who are judged by the College to have advanced the science and art of obstetrics and gynæcology. The Fellowship or Membership of the College is now a necessary qualification for election to the staff of several obstetric and gynæcological hospitals, and it is hoped that, in time, it will be essential for election to the staff of all such hospitals, consequently, all intending to specialise in obstetrics and gynæcology should endeavour to obtain the Membership as soon as possible.

For those practitioners who have had special post-graduate experience in obstetrics and wish to have some tangible proof of this, but whose experience and work does not allow of their admission to the Membership, the College has instituted a diploma, (D.C.O.G.). Candidates for it must produce evidence of post-graduate experience in general medicine or surgery and obstetrics and gynæcology. The obstetrical experience must have been obtained in a resident appointment. At the present time applications by general practitioners who have had special experience in obstetrics but have not held a resident appointment and cannot now do so are specially considered by the examination committee, although in the near future it is intended to adhere strictly to the regulations.

The regulations for the Membership and Diploma may be obtained from the Hon. Secretary, The British College of Obstetricians and Gynæcologists, 58, Queen Anne-street, London, W.1.

SOCIETY OF APOTHECARIES OF LONDON

The Pre-Medical and Primary Examinations are held quarterly. The Pre-Medical includes Chemistry, Physics, and Elementary Biology. The Primary includes Anatomy, Physiology and Histology, Materia Medica, and Pharmacy. The latter examination cannot be passed before the completion of five terms' Physiology and Practical Anatomy with Demonstrations, and the first two subjects cannot be taken separately except in the event of the candidate having previously passed in one, and obtained at least half the marks required to pass in the other.

The Final Examination for the Licence (L.M.S.S.A. Lond.) is held monthly, except in September. (A) Principles and Practice of Surgery, including Surgical Pathology, Surgical Anatomy, Operative Manipulation, Instruments and Appliances. (B) Principles and Practice of Medicine, including Therapeutics, Pharmacology, Medical and General Pathology, Bacteriology, and Morbid Histology. (C) Midwifery, Gynæcology, Diseases of New-born Children, and the Use of Obstetric Instruments. (D) Forensic Medicine, Hygiene, Mental Diseases, and the Theory and Practice of Vaccination. The examination is partly written, partly practical, partly clinical, and partly oral. Sections A, B + D, and C may be taken at separate examinations, but there is no exemption from any part of the Final Examination.

The minimum period of medical study extends over five years (57 months), and three academic years (33 months) must elapse after a candidate has passed the examination in Anatomy and Physiology before he can complete the *Final Examination.* The course of study for the Final Examination includes attendance on the Surgical and Medical Practice with Post-mortem Examinations, at a hospital connected with a medical school for a period of three winter and three summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The offices of dresser and clinical clerk must have been filled at a hospital or institution recognised by the Society.

The certificates prescribed by the Regulations must be produced before admission to the respective sections of the Final Examination.

Master of Midwifery.—The examinations for this Diploma are held in May and November. Candidates will be admitted to the examination who have been registered practitioners for at least three years and who have held a resident appointment in an institution recognised by the Society for six months or more, and who for three months in each case have attended an antenatal clinic and an infant welfare centre, also recognised by the Society. Medical officers employed by a public health authority, and having special duties connected with Maternity and Child Welfare, will be admitted to the Examination on production of evidence to that effect. The examination will be conducted by written papers and by clinical and oral tests.

Candidates for the examination must send in their certificates to the Registrar, who will supply any other information.

METROPOLITAN CENTRES AFFORDING EDUCATIONAL FACILITIES

Certain organisations and institutions provide for the needs of the medical student in his curriculum and for the post-graduate student requiring special forms of instruction and opportunities for clinical observation. Many of the institutions are recognised by the English Conjoint Examining Board as a place of study for the fifth year of the curriculum.

Special Diplomas in public health, tropical, psychological, and ophthalmic medicine, medical radiology and electrology, laryngology, otology, and tuberculosis are now granted in proof of intensive work along the different lines indicated. Of these, the Diploma in Public Health, being regulated by the General Medical Council, is registrable. Appointments to and promotion in the various Services are largely dependent on the possession of a particular diploma, and each syllabus of the special courses available at the institutions which follow, either with or without association with the Fellowship of Medicine, is planned to afford the necessary instruction.

The Special Diplomas are dealt with fully on p. 529, where the Bethlem Royal Hospital, the Maudsley Hospital, and the Diploma in Psychological Medicine are referred to. Similarly the Hospitals of the Metropolitan Asylums Board provide post-graduate as well as under-graduate facilities, while the hospitals of the Seamen's Hospital Society both supply the instruction necessary for the Diploma in Tropical Medicine and Hygiene, and coöperate in the activities of the Fellowship of Medicine and Post-Graduate Medical Association.

The Fellowship of Medicine and Post-Graduate Medical Association

Some 50 general and special London hospitals work in conjunction with this Association, which has its office at Room 28 in the House of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1. Arrangements are made for courses in medicine and in surgery and the specialties, occupying the whole or part of each day for periods of one to four weeks. Daily clinical teaching arranged. Special evening clinical courses for the M.R.C.P. and F.R.C.S. (Primary and Final) Examinations are organised at intervals. Courses, demonstrations, and lectures arranged by the Fellowship of Medicine are open only to members of the Fellowship. The membership fee is £1 1*s.* per annum, which includes the subscription to the monthly *Post-Graduate Medical Journal.* The provisional list of Special Courses impending will shortly be available. Full information regarding the courses of study and fees can be obtained from the Secretary.

Infectious Hospitals of the London County Council

Classes of instruction in fevers for undergraduate medical students are given at the various hospitals, normally commencing in January, May and October each year. The minimum duration of the course is two months, and sixteen attendances are necessary before a certificate can be granted to a student that he has satisfactorily completed his course. The prescribed fee for a two months' course is £3 3*s.* The medical superintendents arrange direct with the deans of the medical schools concerned as to the days and hours of the classes. Students desiring to take this course should apply to their dean for information. In addition, classes of instruction for the Diploma of Public Health, which comply with the rules of the General Medical Council for that Diploma, are given at two of these hospitals—viz., North-Western Hospital and Brook Hospital. The minimum duration of this course is three months, and twenty-four attendances are necessary before certificates can be granted. The prescribed fee for a three months' course is £3 13*s.* 6*d.* Full particulars relating to these classes may be obtained on application to the Medical Officer of Health. London County Council, Public Health Department, Special Hospitals Division, County Hall, Westminster Bridge, S.E.1.

Seamen's Hospital Society

The Society possesses six establishments: the Dreadnought Hospital at Greenwich, 257 beds; the Albert Dock Hospital, E.16, 53 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, W.C.1, 76 beds; Tilbury Hospital, Tilbury Docks, Essex, 94 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds; and the Angas Home, Cudham, 36 beds. Courses of operative surgery and surgical pathology are arranged by the London School of Clinical Medicine at the Dreadnought Hospital. Post-graduate Courses for Ship Surgeons are organised by the Society, Part II. (Tropical Medicine and Hygiene) being held at the London School of Hygiene and Tropical Medicine, commencing April 11th, and Part III. (Refresher Course in clinical subjects) at the Dreadnought Hospital, Greenwich, commencing in October.

The clinical teaching of the London School of Hygiene and Tropical Medicine is given at the Society's Hospital for Tropical Diseases, Endsleigh-gardens, W.C.1.

GENERAL

Royal Northern Group of Hospitals

The Royal Northern Hospital, Holloway, London, N.7, is the main institution of the Royal Northern Group of Hospitals, which includes the St. David's Wing for private patients, the Royal Chest Hospital, City-road, E.C., Grovelands Hospital (Recovery Branch), Southgate, the Maternity Nursing Association, and the Reckitt Convalescent Home, Clacton-on-Sea. The total number of beds in the group is 466. Besides the honorary staff, there are six anæsthetists, two pathologists, medical and surgical registrars, resident medical officer, two resident house physicians, three resident house surgeons, two resident casualty officers, one resident obstetric surgeon, and one resident anæsthetist. The large rectangular and circular wards, each of which contains 25 beds, the maternity ward and children's ward for children up to 5 years of age, the observation wards in the new Casualty Department, the six operation theatres, and out-patient department are designed with a view to offer the greatest facilities for clinical work. The Special Departments include the following: orthopædic, genito-urinary, and neurological, physiotherapeutic, pathological, tuberculosis, venereal diseases, and X ray (recently remodelled). Patients are removed to the Recovery Branch by ambulance a few days after operation. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments, and may receive certificates at the end of their terms of office. A new maternity department has been opened and the light department has been re-equipped. A complete hospital for paying patients has just been completed.

Post-graduate lectures and demonstrations are arranged from time to time, as advertised in the medical press.

Prince of Wales's General Hospital

This hospital, situated in Tottenham, is in the midst of a densely populated neighbourhood, and contains medical, surgical, gynæcological, and children's wards, having 238 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction is given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are six resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are also held at intervals throughout the year.

West London Hospital

This hospital has 220 beds. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved for qualified men and those referred in the final examinations. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. The accommodation for post-graduates consists of a lecture-room, together with reading, writing, and class-rooms. The hospital has a fully equipped pathological laboratory. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave, and by the Conjoint Board of Examiners.

National Temperance Hospital

The hospital (Hampstead-road, N.W.) contains 152 beds. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Monday, 1.30 P.M.; Tuesday, 2 P.M.; Wednesday, 2 P.M.; Thursday, 9 A.M.; Friday, 11 A.M. Out-patient departments for the following classes of case have been opened: dermatology, ophthalmology, oto-rhino-laryngology, diseases of the chest and of the rectum. There is also an out-patient gynæcological clinic.

Hampstead General and North-West London Hospital

In-patient Department: Haverstock Hill, N.W.; Out-patient Department: Bayham-street, Camden Town (138 beds—viz., 109 free, 8 isolation and observation, and 21 paying or contributory). Serves Hampstead and the populous districts of Kentish Town and Camden Town. The out-patient and casualty departments are at Bayham-street, Camden Town. Hampstead casualties are received at Haverstock Hill. In addition, consultative clinics are held at Haverstock Hill, where patients are seen upon presenting letters from their doctors. There is a post-graduate School free to the medical practitioners of the district. The hospital is also associated with the Fellowship of Medicine.

Metropolitan Hospital

This hospital has 150 beds, 17 of which are reserved for children. The adult accommodation includes special wards for the reception of Hebrew patients, and there is a Kosher kitchen and Jewish cook. Operations are held in the afternoons daily, except Wednesdays, Saturdays, and Sundays. The out-patient department is a large one, and has facilities for the treatment of all diseases; Jewish patients can attend special sessions. Special departments comprising: Neurological, Ophthalmic, Rectal Diseases, Diseases of Women, Genito-urinary, Diseases of the Throat and Ear, Eye and Skin, Electrotherapeutics, Dental, and V.D. Attached to the hospital is a Tuberculosis Dispensary for patients from the boroughs of Hackney and Stoke Newington.

Queen Mary's Hospital for the East End

This hospital has developed from the West Ham and Eastern General Hospital. It has 219 beds and ministers to a very poor public. Founded as a dispensary in 1861, and developing into a hospital in 1890, steady extensions have been made during this century. A Royal Charter was obtained in 1917, and the hospital has become a valuable charity with a full medical staff of physicians and surgeons, and specialists for gynæcology, obstetrics, ophthalmological surgery, radiology, dermatology, and dental surgery. The Fellowship of Medicine makes frequent use of the opportunities.

NEUROLOGY

National Hospital, Queen-square

The hospital, with the Convalescent Home at East Finchley and branch at Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Wednesday, Thursday, and Friday at 2 P.M., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held twice every year, usually commencing in January and October, and lasting about nine weeks. Special courses in Neurological Ophthalmology, Neuropathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist.

West End Hospital for Nervous Diseases

This institution is recognised by the University of London and by the Conjoint Board as a school of instruction in Neurology for the M.D. degree, Branch III., and for the D.P.M. The Out-patient Department is in Welbeck-street, W.; the In-patient Department is at Gloucester-gate, Regent's Park, and contains 76 beds. Completely equipped with pathological and other special departments, the hospital offers every facility for instruction in Neurological subjects, including courses of instruction for the D.P.M. The hospital coöperates with the Fellowship of Medicine in the programmes of special post-graduate teaching organised by the Association. A concentrated week's course for general practitioners will be held this year from Oct. 21st.–26th. The practice of the hospital is open to students and practitioners by arrangement. Appointments as Hon. Clinical Assistants in the Out-patient Department are open to registered medical practitioners. Two Resident House Physicians are appointed for a period of six months in the first place with remuneration at the rate of £125 per annum. Vacancies March 1st and Sept. 1st. The Savill Memorial Prize (value £15) and Medal are offered biennially for competition among post-graduate students who have attended the practice of the hospital or any special course.

Hospital for Epilepsy and Paralysis

This hospital in Maida Vale, W., contains 88 beds, including 20 private wards and 6 pay beds. Both in-patient and out-patient departments are open free to students, as well as to medical graduates. The out-patient department is open every week-day except Saturday at 2 P.M.

HEART AND LUNGS

Royal Chest Hospital

The Royal Chest Hospital, City-road, E.C., associated with the Royal Northern Group of Hospitals, has accommodation for 84 in-patients and a large out-patient department, open daily. Special departments include Thoracic Surgery, Laryngology, Radiology, Electrocardiograph, Massage and Physical Exercises, and an Ultra-violet Light clinic. Clinical Assistants are appointed to work with the physicians in the out-patient department. The Tuberculosis Dispensary for Islington South is attached to the hospital.

Brompton Hospital for Consumption and Diseases of the Chest

The hospital contains 368 beds, of which 57 are allocated to the Surgical side and 98 to Paying Patients. A further 150 beds are provided at the Sanatorium at Frimley, which also contains beds for paying patients. The beds for paying patients at the hospital are so divided up as to provide Wards of two and five beds each at a small inclusive fee, and single bedrooms in which the fees are non-inclusive. In addition to the resident medical officer there are two resident surgical officers appointed annually; an assistant resident medical officer, who assists in the artificial pneumothorax clinic, and six resident house physicians, whose duties include attendance at the out-patients' and special departments, and one of these serves as assistant to the tuberculosis officer for Chelsea; these officers are appointed for a term of six months each. Post-graduates are admitted to the practice of the hospital. Clinical assistants are appointed to the in-patient and out-patient physicians, the surgeons, and the special departments of the hospital. Clinical demonstrations in the Wards, the out-patient and special departments are given throughout the year, and two special post-graduate courses of one week each and three week-end courses are held annually. Special courses are also held o! the Pathological Department. The medical practice of the hospital is recognised by the Conjoint Board, the University of London, the Apothecaries Society, and the Army and Navy and Indian Medical Boards. Four special courses for students of eight demonstrations each are held during the year before each final Conjoint Board Examination.

City of London Hospital for Diseases of the Heart and Lungs, E.2.

(188 beds). Special Departments: Surgical, Laryngological, Bronchoscopical, Radiological, Pathological, Electrocardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The in-patient staff visit generally in the afternoon; out-patients at 2 P.M. Graduates are admitted on payment of fees which entitle them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, and a club room. Graduates desiring Assistantships in any department should address applications to the Head of that department. A Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney) is established at the hospital.

National Hospital for Diseases of the Heart

The practice of the hospital, with 46 beds and a large out-patient department, is open daily to post-graduates and others. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, June–July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the cardiovascular system, and facilities exist for those requiring practical instruction in electrocardiography, X rays, and other graphic methods. Clinical Assistants in the out-patient department are appointed from time to time.

DISEASES OF WOMEN AND CHILDREN

Hospital for Sick Children

The hospital is situated in Great Ormond-street, W.C., contains 252 beds, and has an Out-patients' Department attended by some 30,000 new cases each year. There are Asthma, Dental, and Rheumatic Clinics. The practice is open to students of both sexes who have completed four years' medical study and also to qualified medical men and women. Special lectures are given at the hospital weekly; details of these appear in the medical notes published from time to time in the columns of this journal. Clinical instruction is given daily by Members of the Honorary Medical Staff. Clinical Clerks are appointed once a month. These appointments are open to students of recognised medical schools. Arrangements have been made with the London School of Medicine for Women for the routine admission of their students for Clerkships in the wards. Time spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge as part of the final curriculum. Facilities are afforded to post-graduates for obtaining theoretical and practical instruction in Clinical Pathology, Bacteriology, and Medical Biochemistry in the Laboratories.

Queen Charlotte's Maternity Hospital and Midwifery Training School

This hospital, formerly Queen Charlotte's Lying-in Hospital, is situated in Marylebone-road, N.W. The hospital receives over 2700 patients annually, besides having a large out-patient department. Medical students and qualified practitioners are received at all times of the year. They have unusual opportunities of seeing obstetric complications and operative midwifery on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. They also receive valuable instruction in the Antenatal and Child Welfare Departments, where over 4000 patients attend yearly. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and maternity nurses are received and specially *trained*. A Residential College provides accommodation for students and qualified practitioners (both men and women), and is opposite the hospital, with which it is in telephonic communication.

Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council.

The Isolation Block (30 beds) for Puerperal Fever and Puerperal Pyrexia, which has been built on the new site at Ravenscourt Park, Hammersmith, was opened for the reception of patients in September, 1930, and the Research Laboratories, which have been erected adjoining this block, are in full working order. Students may attend the clinics conducted by the staff at the Isolation Block, and demonstrations are also given at the Research Laboratories.

City of London Maternity Hospital and Midwifery Training School

This hospital (City-road, E.C.) receives nearly 1700 in-patients annually, in addition to attending mothers in their homes. Pupil Midwives and Maternity Nurses receive the recognised course of training, assisted by a Sister Tutor. Monthly or fortnightly residential courses are provided for two Medical Students at a time and facilities are offered to post-graduates to see the work of the Antenatal Clinics on three mornings weekly. For the benefit of post-graduates, occasional week-end courses are arranged through the Fellowship of Medicine. Refresher courses are provided for Practising Midwives.

Royal Waterloo Hospital for Children and Women

This hospital has now 130 beds, while the latest buildings include a Nurses' Home and private pay beds. It has a full staff of surgeons, physicians, and gynæcologists, and also special departments. Amongst the many valuable additions to the equipment of the hospital is an Electrocardiograph apparatus. A newly equipped Orthopædic Department is in use, and the Physiotherapeutic and Electrical Department has been extended and re-equipped. There are facilities for post-graduates to attend the general and special clinics in medicine and surgery for in-patients, and for out-patients, including a genito-urinary clinic, a clinic for varicose veins, a L.C.C. Clinic for children suffering from rheumatic fever and chorea, and the X ray department for gastro-intestinal diagnosis. Particulars of post-graduate courses, which are held from time to time, can be obtained from the Secretary of the hospital.

Victoria Hospital for Children

This hospital in Tite-street, Chelsea, S.W., contains 138 beds and a large out-patient department; the home at Broadstairs has 50 beds. There are two private wards where patients may be under the care of any medical practitioner holding an appointment on the staff of a recognised hospital, and the question of payment for his fees is arranged between him and the child's parents.

Queen's Hospital for Children

This hospital, for the sick children of the poor up to 14 years of age, was formerly known as the North-Eastern Hospital for Children. There are 160 beds in London (Hackney-road, E.2) and 44 at the seaside branch, Little Folks Home, Bexhill. Special departments in Ear, Nose, Throat, Skin, and Eye, and Dentistry. Rheumatic Clinic in coöperation with L.C.C. schools twice weekly. A radiologist attends four times weekly. There are massage and light departments, and a special whooping-cough physician. The practice of the hospital is open to students by arrangement with the medical staff.

Paddington Green Children's Hospital

This is a hospital of 52 beds, with a large out-patient department and a full staff, with Eye, Ear, Skin, Light, Psychology, Rheumatism, X ray, and Dental departments. The facilities which it offers for observation of clinical practice are used by the Fellowship of Medicine.

Hospital for Women, Soho

This hospital in Soho-square, W., contains 81 beds. The teaching is available for post-graduates only in limited numbers. Operations take place on Mondays and Fridays at 9.30 A.M., Tuesdays and Thursdays at 2 P.M., and Wednesdays and Fridays at 3 P.M. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated is the London School of Gynæcology, comprising attendance in out-patient department, operating theatre, clinical lectures, and X ray treatment.

Samaritan Hospital for Women

Contains 88 beds. Qualified practitioners are admitted as clinical (gynæcological) assistants to both the in- and out-patient departments. Full particulars may be obtained from the Secretary to the Medical Committee at the hospital, Marylebone-road, N.W.

cess Elizabeth of York Hospital for Children

The hospital in Shadwell, E.1, has 135 beds. Clinical instruction in pædiatrics is given to the fifth-year students in Glamis-road, Shadwell, E.1. Two clinical clerkships for students or medical men for a period of three months are available. Clinical assistants are, from time to time, appointed in the out-patient department. There is an orthopædic clinic on Wednesdays and a rheumatic clinic on Saturdays. Physicians and surgeons pay ward visits every morning and periodical intensive courses in pædiatrics, medical and surgical, are given. From time to time post-graduate courses are arranged at the hospital by the Fellowship of Medicine, when most of the honorary staff give lectures. The hospital is always ready to arrange these courses.

An appeal has been launched to build a hospital and convalescent home on an estate at Banstead, which has recently come into the possession of the institution. The present convalescent home, now at Bognor, will be transferred to Banstead, and the whole will be under the charge of the honorary staff, when further facilities for post-graduate instructions will be offered.

Chelsea Hospital for Women

This hospital has 104 beds; 18 for patients paying £5 5s. a week and moderate fees to the surgeons for operations. There is a convalescent home of 32 beds at St. Leonards. In the out-patient department the patients are seen at a nominal payment or with subscribers' letters. The hospital caters for post-graduate teaching. In the out-patients' department clinical assistantships can be obtained which entitle the holder to attend and examine patients under the instruction of the visiting surgeons. The operating theatre is open to visitors, and all operations are demonstrated and discussed by the surgeons. The Pathological Department contains one of the finest gynæcological museums in the country. Special intensive courses, with lectures and special demonstrations, are held three times a year through the organisation of the Fellowship of Medicine.

Evelina Hospital and Belgrave Hospital

The Evelina Hospital, Southwark (80 cots), and the Belgrave Hospital (76 cots), Clapham-road, also give facilities for out-patient practice.

CANCER

Cancer Hospital (Free)

The hospital, situated in Fulham-road, S.W., contains 129 beds for poor persons afflicted, who are admitted free. The Out-patient Department is open every week-day, except Saturday, at 2 P.M., also Wednesday morning at 10 and Saturday morning at 11. A course of study in Physics and Radiology, qualifying for the Diploma in Medical Radiology, is given. The hospital is a recognised teaching school of the University of London, in Medical Radiology, Experimental Pathology, and Pathological Chemistry. Senior and Junior Resident House Surgeons are appointed for a period of six months at a salary at the rate of £100 per annum.

Mount Vernon Hospital

The hospital contains 130 beds for surgical cancer cases. Clinical Demonstrations are given by the visiting Surgical Staff at the hospital at Northwood. Clinical assistants are appointed to surgeons in the wards. Diagnostic and follow-up departments, 14, Riding House-street, W. Further information can be obtained from the Secretary, 32, Fitzroy-square, W.

Marie Curie Hospital

This hospital, which is officered by medical women, is a radium centre for the treatment of women suffering from cancer and allied diseases. The In-patient Department contains 39 beds, of which eight are for private patients. There is a daily Out-patient Clinic to which cases are sent for diagnosis and at which the cases already treated by radium are kept under observation. A department for deep X ray therapy was opened in January, 1934. A radiographic department will be in working order immediately. The practice of the hospital is open to graduate visitors, and one graduate wishing to study the subject of radiology is accepted for full-time service for four to six months.

OPHTHALMOLOGY

Royal London Ophthalmic Hospital

The attendance at Moorfields Eye Hospital (Moorfields, 1804–1899), City-road, E.C. (152 beds), is now very large. Operations are performed each day from 10 A.M. to 1 P.M. and four surgeons attend daily. Students are admitted to the practice of the hospital and special courses of instruction are given, which extend over a period of five months, by members of the surgical staff and certain outside lecturers, beginning in October and March. The instructions and classes are arranged to meet the requirements for the various diplomas in Ophthalmology, both for the preliminary examinations in Anatomy, Physiology, and Optics, and those subjects required in the second part. Students of the hospital are eligible as house surgeons, out-patient officers, and clinical assistants. The senior resident officer and three house surgeons are appointed every six months. Twenty-four out-patient officers are appointed each year. Clinical assistants are appointed every three months. The rebuilding of the Out-patients' Department, Medical School, and Private Wards is now completed, and the building is in use. All these departments are now very much improved, as well as the arrangements for instruction.

Royal Westminster Ophthalmic Hospital

This hospital, in Broad-street, Holborn, W.C. (88 beds, including 14 rooms for paying patients), has removed from its original site at Charing Cross to much larger premises, well adapted for teaching purposes. The clinics are held in the afternoons from 1.30 P.M. Operations are performed daily in the theatre at 3 P.M. Lectures and practical classes in the various branches of Ophthalmology, including Operative Surgery, Bacteriology, and Pathology, are held during the winter and summer sessions at 5 P.M. The practice of the hospital is open to both men and women practitioners, and medical students. Post-graduate students at the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction officer (seven appointments paid), and senior and junior assistants.

Royal Eye Hospital

There are 46 beds at this hospital, which is situated in St. George's-circus, Southwark, S.E., and an annual attendance of 68,000 patients. The staff attend daily, Mondays to Fridays at 2 P.M., and on Saturdays at 9.30 A.M., when clinical instruction is given. Special classes held in May and October are planned to meet the requirements of students preparing for the D.O.M.S. and similar examinations, and cover Anatomy, Physiology, Optics, Clinical Ophthalmology, Operative Surgery, and Pathology. Clinical Classes in medical ophthalmology are held for candidates for the M.R.C.P. examinations. A Course suitable for general practitioners is held in April under the auspices of the Fellowship of Medicine. Apart from the Honorary Staff of six Surgeons, there are also a Pathologist, a Bacteriologist, two resident House Surgeons, 12 Chief Clinical Assistants, 24 Clinical Assistants, 14 L.C.C. Refraction Officers, 10 Hospital Refractionists, and an officer in charge of the Squint Training Clinic. Reference departments for general medicine, neurology, dental treatment, ear, nose, and throat investigations, orthoptic training, and radiology, including ultra-violet therapy, are available. The pathological and bacteriological departments are available to ophthalmic surgeons and institutions desiring reports on specimens, cases of interest being dealt with without charge. A Research Scholarship in Ophthalmology to the value of 100 guineas per annum is awarded yearly.

Central London Ophthalmic Hospital

This hospital, in Judd-street, St. Pancras, W.C., has 51 beds, and clinical teaching is given daily. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. An Orthoptic Department for the treatment of cases of squint has been established, and pupils are taken for training in this work. Voluntary ophthalmic clinics are held on Mondays and Thursdays at 4.30 P.M. Ten private rooms are available for private patients. A department for research into and development of the corneo-plastic surgery of the eye has recently been established.

GENITO-URINARY AND VENEREAL DISEASES

London Lock Hospital and Home

There are 74 beds for men, women, and children. Male out-patients are seen at 91, Dean-street, Oxford-street, W.1, at any time from 10 A.M. until 10 P.M. daily (Sunday, noon–10 P.M.). Intravenous injections are given at every clinic. Irrigations for males are given daily from 9 A.M. to 10 P.M. Female out-patients and children are seen daily at 283, Harrow-road, Paddington, W.9, from 9 A.M. until 8 P.M. Irrigations for females are given at any time. The hospital is linked up with the Fellowship of Medicine; special courses of lectures are held in May and November each year, and application for tickets should be made direct to the Secretary of the Fellowship. Only a limited number of practitioners and students are permitted to attend the practice of the Female Lock Hospital, and application should be made to the Dean at the Male Lock Hospital between the hours of 11 A.M. and 5 P.M.

St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum

At St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City-road, E.C. (founded 1835), for men and women, there are 63 general beds and 9 private beds. Operations are performed on Mondays, Tuesdays, Wednesdays, and Thursdays at 2 P.M. and Saturdays at 11 A.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Four weekly courses are held during the year in coöperation with the Fellowship of Medicine.

St. Peter's Hospital for Stone

The hospital in Covent Garden is thoroughly up to date in all departments, and research is still carried out with radium specially loaned for the purpose by the British Empire Cancer Campaign. Medical practitioners and students are invited to attend the practice of the hospital in the out-patient department, excepting that the only clinic open to medical women is that held at 9.30 A.M. Fridays for women and children. The operating theatre is open to medical visitors as follows: Mondays, Tuesdays, Thursdays 2 P.M., Fridays 2.30 P.M. Special courses of lectures and demonstrations lasting a fortnight are held periodically by arrangement with the Fellowship of Medicine.

All Saints' Hospital

The in-patient department of the All Saints' Hospital for Genito-Urinary Diseases is at Austral-street, West-square, St. George's-road, S.E., contains 55 beds, including those in 4 private wards and cubicles, and the terms of admission are free or by payment according to means. The out-patient department provides clinical instruction through the Fellowship of Medicine, in addition to which demonstrations in cystoscopy and other branches of genito-urinary work are available for all medical practitioners at the out-patient department on Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday afternoons at 2 P.M., without fee.

ORTHOPÆDICS

Royal National Orthopædic Hospital

This institution, situated in Great Portland-street (480 beds), is a good example of the fusion of scattered activities for the creation of an effective whole. The three orthopædic hospitals of the metropolis were combined for the formation of this central institution at the instance of King Edward's Hospital Fund, with the result that the grants from this Fund and the income from subscriptions can now be used to far better purpose and with economy. The hospital has also been approved by the Ministry of Health for the treatment of surgical tuberculosis, the connexion between orthopædics and the therapeutics required in many forms of tuberculosis having become obvious. Country branch at Brockley Hill, Stanmore (280 beds). Both branches of the hospital are residential schools for physically defective children, certified by the Board of Education. A post-graduate course of 14 days is held about March each year. The out-patient department (entrance in Bolsover-street) is open every week-day, except Saturday, at 1.30 P.M. The Evening Clinic on Tuesdays from 6 P.M. to 8 P.M.

EAR, NOSE, AND THROAT

Central London Throat, Nose and Ear Hospital

This hospital in Gray's Inn-road (78 beds) is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinic. Lectures each Friday at 4 P.M. Courses in Anatomy and Physiology for Part I. of the D.L.O. Examination by a Teacher of Anatomy and Clinical Courses by the Honorary Medical Staff for Part II. of the Examination are given twice yearly, in May and October. In addition there are Peroral Endoscopy and Pathology and Bacteriology classes. Courses in methods of Examination and Diagnosis are given at frequent intervals during the year. Clinical Assistants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening clinics. New wing, with complete out-patient department and additional wards, was opened in August, 1929, and a Recovery Home at Ealing with 26 beds was opened in July, 1933.

Golden-square Throat, Nose, and Ear Hospital

The hospital (101 beds), which has absorbed the London Throat Hospital, is situated in Golden-square, near Piccadilly Circus. Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 4 P.M., and on Tuesdays and Thursdays from 6.30 to 7.30 P.M. There is an annual out-patient attendance of 40,000. Minor operations are performed on Wednesdays and Fridays at 9.30 A.M. The hospital now contains 101 beds, of which 11 are for private patients. There is also semi-private accommodation at 4 guineas a week inclusive. Practitioners and post-graduate students are admitted to the practice of the hospital, and clinical assistants are appointed periodically.

Metropolitan Ear, Nose, and Throat Hospital

The hospital is in Fitzroy-square and contains 22 beds. The out-patient department is opened daily at 2 P.M., Saturdays 1 P.M., to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, Thursdays, and Fridays at 10 A.M. Clinical Assistants are appointed as vacancies occur.

SKIN

London School of Dermatology

The London School of Dermatology, St. John's Hospital for Diseases of the Skin, has an in-patient department (40 beds) at 262, Uxbridge-road, W., and out-patient clinics, at 49, Leicester-square, W.C.2, are held daily at 2 and 6 P.M. (Saturdays 2 P.M. only), when demonstrations are given on the cases presenting themselves. The Chesterfield Lectures, constituting a systematic course in dermatology, are given on Tuesdays and Thursdays at 5 P.M., during October and November and January and February, by the hon. medical staff of St. John's Hospital and the physicians in charge of the Dermatological Departments of the London Teaching Hospitals. The lectures are free to those attending the practice of the hospital and to registered medical students. At the end of the course an examination is held for the Chesterfield Medal in Dermatology, and is open to all medical practitioners. A summer course of lectures is also held during the month of May each year. The electrical department is open, Monday to Friday inclusive, from 2 to 7 P.M. Laboratory Courses in the Pathology and Bacteriology of the Skin can be arranged.

London Skin Hospital and Hospital for Diseases of the Skin

The hospitals admit graduates to their practice, which is among out-patients. London Skin Hospital, daily at 2 P.M. and 5.30 P.M., Saturdays 2 P.M. only. Hospital for Diseases of the Skin, daily at 2 P.M., and Fridays, 5.30 P.M., not on Saturdays.

CENTRES OUTSIDE LONDON AFFORDING EDUCATIONAL FACILITIES

Nearly every hospital of a general character in the country having more than 150 beds falls within this category, and certain of them have already been noticed in connexion with the universities to which their clinical practice is attached. The hospitals vary much in size and scope.

The following alphabetical list includes the provincial hospitals which are recognised by the English Conjoint Board for a part of the required training in medical and surgical practice through clerkships and dresserships. Further information can be obtained from the secretaries of the institutions.

Bath Royal United Hospital

This hospital contains 284 beds of modern construction, 72 of which are for paying patients only; possesses X Ray, Massage, Bacteriological Departments; a Pathological Laboratory, Obstetric and Gynæcological, Ear, Nose, and Throat, and Skin and Neurological Departments. Secretary-Superintendent: Mr. J. Lawrence Mears. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), at 5 P.M. The appointments of house surgeons are recognised by the Royal College of Surgeons to qualify candidates for the Final Fellowship examination. A post-graduate course is held every autumn and a programme of clinical ward rounds is carried out during the first six months of each year.

Bedford County Hospital

This hospital at Bedford has 124 beds, including 15 beds in the paying and 13 beds in the maternity wards; Ear, Nose, and Throat Departments, and X Ray and Pathological Departments. There is in connexion with the institution a convalescent home (20 beds) at Aspley Heath, near Woburn Sands. The hospital is approved by the English Conjoint Board for the examinations.

Berkshire Royal Hospital

This hospital at Reading, which contains 274 beds, includes an Out-patient Department, a Casualty Department, an X Ray and Radiotherapeutic Department, Electrotherapeutic and Massage Department, an Orthopædic Department, an Orthoptic Clinic, a V.D. Clinic, a Laboratory, an Eye Theatre, Eye Wards, a Maternity Ward, a Paying Patients Unit, and a Private Nursing Staff, and two motor ambulances. The hospital is approved as a Training School for Nurses and by the Ministry of Health for V.D. Treatment. The Blagrave Branch, Calcot, contains in addition to the above 64 beds for cases of disease of bones and joints and those requiring open-air treatment.

Bradford Royal Infirmary

This hospital at Bradford contains 223 beds and, in addition, has 50 recovery beds at the Woodlands Convalescent Home, Rawdon. The acting staff consists of 4 Honorary Physicians, 4 Honorary Surgeons, 1 Honorary Radiologist, 1 Honorary Laryngologist, 1 Honorary Ophthalmic Surgeon, 1 Honorary Dental Surgeon, 1 Honorary Assistant Dental Surgeon, 2 Honorary Assistant Physicians, 2 Honorary Assistant Surgeons, 6 Anæsthetists, 1 Pathologist, 1 Physician-in-charge of Radium Therapy Department, 1 Resident Surgical Officer, 1 House Physician, and 4 House Surgeons. There are special clinics for Orthopædic cases, for Electro-therapeutic and Sunlight Treatment, and for Radium Therapy cases. A new hospital of 336 beds is in construction, and a self-contained block for 70 paying patients has been opened adjoining the new Infirmary.

Coventry and Warwickshire Hospital

There are 307 beds available at the Main Hospital at Coventry (established 1840), and 40 beds at the Alcock Convalescent Hospital, Keresley (three and a half miles distance), which is used as an annexe. At the Main Hospital there are separate Medical, Surgical, Maternity, Children's, and Accident Wards, also separate Ophthalmic Block complete with its own Theatre. There are separate departments for Clinics for Ear, Nose, and Throat Diseases, X Ray, Electrical, and Sunlight Clinics, also V.D. Clinic. There is also an up-to-date Pathological Laboratory and Cardiograph Department. The hospital is recognised for the D.O.M.S. and the D.L.O.

Derbyshire Royal Infirmary

This general hospital at Derby (362 beds) was rebuilt in 1892–94. In recent years there have been numerous alterations and additions to keep pace with modern requirements. The hospital is built on the pavilion system and provides, in addition to the usual Medical and Surgical blocks, a separate Ophthalmic block of 40 beds, a separate Children's block of 34 beds (Medical and Surgical), Gynæcological Wards, and an Ear, Throat, and Nose Department. There is a large and well-equipped Out-patient Department, also separate Orthopædic, X Ray, Electrical, Pathological, and Venereal Diseases Departments. The salaried Medical Staff consists of a non-resident Staff of 1 Surgeon-in-charge of X Ray and Electrical Departments, 1 Surgeon-in-charge of Venereal Diseases Department, 5 Anæsthetists, and a Resident Staff of 4 House Surgeons, 1 House Physician, and 1 Assistant House Surgeon and Casualty Officer. Registered Medical Students are admitted to witness the medical and surgical practice on payment of fees.

Devon and Exeter Royal Hospital

The hospital at Exeter contains 230 beds (including special children's wards) and has a good library, museum-post-mortem room, and pathological laboratory. A new Out-patients' Department is in course of completion. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. Sun balconies were added in 1933 to this wing. The "Victory" wing is for the treatment of discharged disabled soldiers and sailors. The Electrical Department now forms one of the most important sections of the hospital. At the department for the treatment of genito-urinary diseases there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M. Doctors in practice may use the museum and library.

Prince of Wales's Hospital, Plymouth

The institution incorporates and amalgamates the South Devon and East Cornwall Hospital, Plymouth (240 beds), the Central Hospital, Plymouth (50 beds), the Royal Albert Hospital, Devonport (60 beds). Special departments include: Pathological, X Ray, Deep Therapy, Cardiographic, Ultra-violet Rays, Electrotherapeutic, Orthopædic, Gynæcological, Aural, Dental, Ophthalmic, and Neurological; also Medical and Surgical Out-patients. Pensioners are received as in-patients and are also treated as out-patients. The hospital has been approved by the National Radium Commission as a Regional Centre for the South-West; and a self-contained unit of 26 Pay Beds and Theatre Suite is now provided.

West of England Eye Infirmary

Students of the Exeter hospital can attend the practice of the Eye Infirmary (55 beds). A ward is set aside for newly born babies suffering from infectious eye diseases. Mothers with babies are accommodated.

Gloucestershire Royal Infirmary and Eye Institution

This hospital at Gloucester has 224 beds. Secretary: F. J. Symons. An Electrical and Massage Department has been established and Venereal Clinic opened. Also Ear, Nose, and Throat Department, X Ray, Electrocardiograph, and Ultra-violet Ray Departments, Orthopædic Department, Dental Department, Pathological Laboratory, and Neurological Clinic. Sixteen beds for paying patients in new block.

Hampshire Royal County Hospital, Winchester

This hospital, which was founded in 1736, contains 173 beds. There is a private nursing staff attached. The building and amenities are completely up to date; there are an efficient Out-patient Department, a Pathological Laboratory, Paying Patients Wards, and an Electrical and Massage Department. A new Children's Block has been opened.

Hull Royal Infirmary

This hospital contains 267 beds, plus 100 beds at the branch hospital at Sutton-on-Hull, and has undergone steady additions and improvements, including up-to-date Ophthalmic, Radiological, Nose, Throat, and Ear, Dental, V.D., Violet Rays, and Pathological Departments, and a Clinic for Functional Nervous Diseases was opened in 1931, under the Mental Treatment Act, 1930. Extensions in recent years include a new Operating Theatre, Nurses' Home, and extensions to the old X Ray, Electrical, and Out-patient Departments. The Resident Staff consists of 1 Resident Surgical Officer, 2 House Physicians, 3 House Surgeons, 1 Surgeon to Special Departments, 1 Casualty Officer. Sutton Branch: 1 House Surgeon and 1 House Physician. An annexe at Withernsea has accommodation for 30 patients. The two house physicians' appointments, and that of the house physician at the Branch hospital, are recognised by the University of London for the M.D., Branch I. (General Medicine) examination. It also recognises the posts of senior house surgeon, second house surgeon, and house surgeon of the Branch hospital, for the M.S., Branch I. (General Surgery) examination. The post of house surgeon to the Special Departments is recognised by the Conjoint Board of the Royal Colleges for the examinations for the Diplomas in Ophthalmic Medicine and Surgery, and Laryngology and Otology. The hospital is also recognised by the Royal Colleges for the F.R.C.S. examinations.

Kent and Canterbury General Hospital

The hospital at Canterbury contains 137 beds. Pupils of the staff are admitted to the practice of the hospital. Operations daily. Special departments include Ophthalmic, Ear, Nose and Throat, Venereal, Orthopædic, Electrical, Actinotherapeutic, X Ray, and Bacteriological. Accommodation for paying patients is available. The hospital is recognised for the purpose of M.D. and M.S. examinations.

Leicester Royal Infirmary

At the Leicester Royal Infirmary there are 486 beds (children's 80 and venereal diseases 15); 92 additional beds are retained at local convalescent homes for the reception of pre-convalescent cases. A rebuilding scheme has been carried out providing modern operating theatres, three new wings, a self-contained out-patients' department, pathological laboratories and post-mortem rooms, and special departments. The Children's Hospital was reconstructed and enlarged, and the Nurses' Home recently enlarged to accommodate 220 nurses at a cost of £55,000. There are 13 resident salaried medical officers—viz., four house surgeons, two casualty officers, three house physicians, three anæsthetists, one dresser. The posts are filled half-yearly—April and October—and afford exceptional opportunities for post-graduate experience. Senior students are appointed as dressers and are given an honorarium (applications to the House Governor and Secretary). A post-graduate course of lectures is arranged annually by the Leicester Medical Society, and clinical classes are held for graduates preparing for M.D. and M.R.C.P.

Norfolk and Norwich Hospital

This hospital at Norwich has at present 417 beds. There is a convalescent home with accommodation for 35 patients at Cromer. The Resident Medical Staff consists of one House Physician, three House Surgeons, one House Surgeon to the Ear, Nose, Throat, and Eye Department, and two Casualty Officers. There is also a Private Patients' Home which has at present 25 beds. Students are admitted to the practice of the hospital for a fee of £5 5s. for six months.

Northampton General Hospital

In 1926 a new isolation block of 30 beds was opened. The number of beds is 301. There is an up-to-date Pathological Laboratory; also X ray and therapeutic department and V.D. clinic. Two new operating theatres have been built, and a new ophthalmic in-patient department has recently been completed, also a new deep X ray therapy department. A maternity department is in course of construction and a new children's department and ear, nose, and throat department are being contemplated, also more bedrooms for nurses and a new out-patient department.

Nottingham General Hospital

There are at this hospital 386 beds available for medical and surgical patients, and 110 beds are in the detached branch, known as "The Cedars" Branch of the General Hospital. The honorary staff includes 3 Physicians, 2 Assistant Physicians, 4 Surgeons, 2 Assistant Surgeons, 2 Aural Surgeons, Surgeons in charge of Radium-therapy and Orthopædics, a Physician in charge of the Skin and Ultra-violet Light Departments, a Radiologist, Pathologist, Anæsthetists, and Surgeon-Dentist. The special departments are the Ear, Nose and Throat, Skin, Pathological Dental, Massage, X Ray, Deep X Ray Therapy, Orthopædic, Electrotherapeutic, Ultra-violet Light. The Resident Medical Staff consists of 2 House Physicians, 4 House Surgeons, 1 Aural House Surgeon, and 2 Casualty Officers. The hospital is a recognised training school for nurses.

Portsmouth Royal Hospital

The hospital contains 250 beds. There are Medical, Surgical, X Ray, Massage, Gynæcological, Orthopædic, and Urological Out-patients' Departments. Further particulars may be obtained from the Secretary.

Preston and County of Lancaster Queen Victoria Royal Infirmary

This is a General Hospital with 365 beds, including 72 at two Homes of Recovery. In addition to the Medical and Surgical Wards, there are special wards for Eye, Ear, Nose, and Throat conditions and Venereal Diseases, also a Maternity Department (recognised by the Central Midwives Board). The special departments include Bacteriological, Pathological, Biochemical, X Ray, including Superficial Deep Therapy, Electrocardiograph, Light (including Finsen installation), Neurological, Electrotherapeutical, Ophthalmic, Aural, Orthopædic, Dental, Venereal Diseases (including daily intermediate treatment). Radium treatment is given at the hospital in conjunction with the Manchester Radium Institute. The Visiting Staff consists of 5 Surgeons (4 in consulting practice), 1 Orthopædic Surgeon, 3 Physicians, 3 Radiologists, 2 Eye and Aural, 1 Pathologist, 3 Anæsthetists, 1 Medical Officer to Electrotherapeutic Department, and the Resident Staff—R.S.O., 3 House Surgeons, 1 Casualty Officer, 1 House Physician.

Royal Sussex County Hospital

This (general voluntary) hospital at Brighton has 250 beds and possesses a large out-patient department, including Dental, Dermatological, Ear, Nose, and Throat, X Ray, and Electrotherapeutic sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital on payment in advance of such fees as may be arranged.

Salisbury General Infirmary

This hospital at Salisbury contains 101 beds. Maternity and antenatal ophthalmic wards; and ear, nose, and throat wards; maternity and child welfare clinic. The buildings are now in course of reconstruction. In the extended hospital there will be 225 beds, and there will be 15 new single-bed paying wards, increased ophthalmic in-patient accommodation as well as new and enlarged out-patient accommodation.

Salop Royal Infirmary

This hospital at Shrewsbury contains 185 beds, including a very modern children's ward unit with a special maternity unit for difficult maternity cases. Extensive alterations are at present in progress and will ultimately increase the beds of the hospital to 200, and will include a new double operating theatre unit. A new private patients' wing is also being erected, together with a large pathological institute, which although attached to the hospital will become the central pathological institute for the county of Shropshire. The staff consists of the following honorary officers: 1 consulting physician; 2 consulting surgeons, 3 physicians, 3 surgeons, 3 anæsthetists, 1 obstetric surgeon, 1 radiologist, 1 physician in charge of electrocardiograph department, 1 consulting ophthalmic surgeon, 1 ophthalmic surgeon, 1 consulting alienist, 1 health officer, 3 dental surgeons, and 4 resident officers. The special departments are: electrocardiograph, X ray, massage, electrical therapeutics, ultra-violet ray. There are large out-patients', accidents, and casualty departments.

South Hants and Southampton Royal Hospital

This hospital at Southampton contains 275 beds with every facility for clinical instruction. There have been many alterations and additions in recent years and further extensions are at present in process. The Staff consists of: 4 Honorary Physicians, 4 Honorary Surgeons, 3 Honorary Anæsthetists, 2 Honorary Radiologists, 2 Honorary Ear, Nose, and Throat Surgeons, 1 Honorary Dermatologist, 3 Honorary Dental Surgeons, 1 Pathologist, 1 Physician in charge of Radium Department, and 6 Resident Officers. Special Departments: Ear, Nose, and Throat, Ophthalmic, Dermatological, Electrocardiograph, X Ray, Massage, and Electricity, Ultra-violet Ray, Radium (Regional Radium Centre), Pathological Institute, and large Out-patient Department. Three House Surgeons' posts are recognised for the final F.R.C.S. and one for the D.L.O.

Staffordshire General Infirmary

This hospital was established at Stafford in 1766 and has over 100 beds, and for many years has been recognised for the twelve months' surgical hospital practice required of candidates admissible to the second examination under the conditions of Section IV., para. 11, Royal College of Surgeons, and is a training school for nurses. Paying patients are accepted.

Staffordshire (North) Royal Infirmary

The New Infirmary opened in 1869 at Hartshill, Stoke-on-Trent, built on the pavilion plan, has accommodation for 389 patients, including Children's wards, and a Private Patients' Department of 33 beds. The Infirmary is a Regional Radium Centre (National Radium Commission), and has the following departments: Bacteriological, Pathological, Biochemical, Ophthalmic, X Ray, Electrotherapeutical (including Ultra-violet Ray Lamps), Electrocardiograph, Aural, Dermatological, Neurological, Orthopædic, Dental, Plastic, and Venereal Diseases Clinics, including daily Intermediate Treatments. Recent extensions comprise a new ward block, new X Ray and Orthopædic Departments, with connecting corridors to the existing Infirmary, large extensions to the nurses' home, new boiler house, new chimney stack, new laundry, new surgery and casualty department, new ophthalmic wards, and a new pay beds department.

East Suffolk and Ipswich Hospital

With 335 beds at the hospital in Ipswich, and 65 at the Home of Recovery, the Bartlet Home at Felixstowe, this Institution possesses a total of 400 beds. Although the work is largely surgical, the Medical Wards in the War Memorial Block are quite modern and well situated. Special departments include a children's block with open-air balconies, a complete Ophthalmic Department with operating theatre and wards, a Gynæcological Ward, Uro-Genital Ward and an Isolation block, a Venereal Disease block and a new ward allocated to motor accidents. A complete Ear, Nose, and Throat unit, consisting of six wards comprising 36 beds with operating theatre and offices, was built last year. An entire new X Ray Department has recently been opened. A private patients' block of 46 beds, 30 of which are in the single-bed rooms, has just been put into commission. A Pathological Building was recently erected at a cost of £12,000. A scheme for the enlargement of the Out-patient Department is in progress. The Resident Medical Staff consists of a Resident Medical Officer who is also Medical Superintendent of the Branch Establishment, a Casualty Officer, House Physician, and four House Surgeons. The hospital is recognised by the Council of the Royal College of Surgeons so far as posts of first and second House Surgeons are concerned. Its pharmacy is recognised by the Pharmaceutical Society for Great Britain for practical training. It is recognised as a training school for nurses.

Surrey Royal County Hospital, Guildford

This hospital, established in 1865, has recently been enlarged and thoroughly modernised and, with the further additions which are now being made, will have accommodation for 220 patients, including a paying ward of 22 beds. It has a ward for children, a special operating block with two theatres, anæsthetic, sterilising, and pathological rooms; a large out-patient and casualty department; a fully equipped X ray department and special departments for massage and light treatment. There is a separate pathological block in which every form of investigation necessary for diagnosis and treatment is carried out. There are special departments for orthopædics, diseases of women, of the eyes, of the ears, nose, and throat, of the teeth, and of the nervous system, each being under the charge of a consultant, and in addition there is an Honorary Visiting Staff of four Physicians and four Surgeons as well as four Resident Medical Officers. A resident post at the hospital is recognised as qualifying for admission to the final examination for the F.R.C.S. and the hospital is also a training school for nurses. In the year 1934 the number of in-patients was 2649 and of out-patient attendances, 37,959.

Wolverhampton—The Royal Hospital

There are 300 beds. Special departments: Children, Gynæcology, Maternity, Ear, Throat, and Nose Diseases, Electrotherapeutic and X Rays, Orthopædics, Artificial Sunlight, Venereal Disease, Pathological and Biochemical Laboratories, Dentistry, Radium, Skin Diseases, Psychiatric Clinic, and Electrocardiograph. There is an excellent medical library. The Resident Staff consists of Resident Assistant Surgeon, Resident Assistant Pathologist, one House Physician, and five House Surgeons. Women's Department, one Resident Obstetric Officer and one House Surgeon. Pupils are allowed to witness the whole of the practice of the hospital, and to be present at operations, and have every opportunity of acquiring a practical knowledge of their profession. The hospital is recognised by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice. A course of Practical Pharmacy is given by the Pharmacist. Fees on application. Applications should be made to the Honorary Secretary of the Medical Committee.

Worcester Royal Infirmary

The hospital has 165 beds. An obstetric department and side wards were opened last year and increased the bed accommodation by 16. In 1932 a new wing was added consisting of two operating theatres and a complementary suite of rooms, an Orthopædic and Electro-massage Department, a Pathological Laboratory, an Ear, Nose, and Throat Ward, a Mortuary, Post-mortem Room, Viewing Chapel, and Inquest Room. A new Nurses' Home was also opened in 1932, providing accommodation for Matron, 10 Sisters, and 50 Nurses. The Resident Medical Staff has been increased to three, and a house in the Infirmary grounds has been furnished and equipped for them. All hot water and steam services are run on oil fuel. There is a Department for Venereal Diseases, and Surgical Tuberculosis cases are treated. There is also a Mental Out-patient Clinic.

York County Hospital

This hospital at York contains 200 beds. There are balconies for outdoor treatment, X Ray Department, Orthopædic, Dental, Electrotherapeutic and Massage Departments, actinotherapy installation, and clinical laboratories. There are clinics for Functional Nervous Disorders, Dermatological Disorders, Venereal Diseases, and Electrocardiography.

A new women's surgical ward of 20 beds and a new out-patient department was opened in October, 1934. New clinics for children, heart cases, and skin complaints were started Jan. 1st, 1935.

MEDICAL EXAMINING BODIES AND SCHOOLS IN SCOTLAND

UNIVERSITY OF ABERDEEN

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., *M.D.*, *Ch.M.*, *M.B.*, and *Ch.B.* The Degree of Doctor of Philosophy (*Ph.D.*) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Candidates, before entering on the curriculum, must have passed the Preliminary Examination or hold a qualification recognised as exempting from such examination.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Biology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Forensic Medicine, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital, they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, Radiology, X Ray Therapeutics and Electrical Treatment, and Clinical Chemistry, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A Thesis (in duplicate) has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis (in duplicate) must be presented for approval.

A Diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 80 Bursaries (competition and presentation) ranging in value from £30 to £50 per annum, most of them being tenable from three to five years. Scholarships: five Post-graduate Scholarships, ranging in value up to £250 per annum. Numerous Prizes and Gold Medals reward proficiency in special departments.

Clinical Studies are carried on mainly at the ABERDEEN ROYAL INFIRMARY. There are 370 beds. The main clinical work of the students is done in the infirmary with its general and special facilities, including a department of clinical chemistry. A dietetic department has recently been established under the direction of a qualified dietitian. A post-graduate course in medicine is given during the summer term.

The ABERDEEN ROYAL MENTAL HOSPITAL contains about 900 beds, and a class of mental diseases meets at the University of Aberdeen, and clinical instruction is given at the hospital.

Students also receive clinical instruction at the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, Lying-in and Vaccine Institutions, and the Ophthalmic Institution.

UNIVERSITY OF EDINBURGH

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., *M.B.*, *Ch.B.*, *M.D.*, and *Ch.M.* The degree of *Ch.B.* shall not be conferred on any person who does not at the same time obtain the degree of *M.B.*, and the degree of *M.B.* shall not be conferred on any person who does not at the same time obtain the degree of *Ch.B.* No one is admitted to the degrees who has not been engaged in study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course in Clinical and Practical Midwifery and have personally conducted at least 12 cases of labour. Residence for a period of at least five weeks in a hostel in close proximity to the Maternity Hospital is also required.

With respect to the places and institutions at which the studies of the candidates may be prosecuted the following regulations have effect: Three of the five years of medical study must be spent in the University of Edinburgh. The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised for the purpose by the University Court. Women are admitted to graduation in medicine under the same conditions as men.

Bachelors of Medicine and *Bachelors of Surgery* of not less than 24 years of age may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval.

Edinburgh Royal Infirmary

Clinical instruction is carried on mainly at this institution. There are 1025 beds, including 71 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Diseases of the Skin, Diseases of the Eye, Ear, Nose, and Throat, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat, and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There is also a large and complete Radiological Department in which is given theoretical and practical instruction for the University Diploma in Radiology, &c. In addition to the Out-patient Departments connected with the Surgical and Medical Houses, there are separate Out-patient rooms attached to the Special Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology.

The appointments are: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department.

Among other institutions in which students receive clinical instruction are the following:—

Municipal Hospitals.—The three Municipal Hospitals—the Western General Hospital (300 beds), the Eastern General Hospital (400 beds), and the Northern General Hospital (260 beds)—are available for clinical instruction in Medicine, Surgery, Midwifery, and Diseases of Children throughout each term and during vacation. Accommodation is provided for resident students who act as clinical assistants, and the experience gained by such residence has proved to be a useful addition to the ordinary clinical classes and of great value to the student.

Edinburgh Royal Hospital for Sick Children

This hospital, which is situated within easy distance of the University and the Royal Infirmary, contains about 120 beds, of which 50 are reserved for surgical cases. It is fitted with every modern improvement and has a fully equipped out-patient department for both medical and surgical cases. Clinical instruction is given in the hospital by the professor of child life and health and the university lecturers in diseases of children. The course which includes lectures and clinical teaching covers the care and management of the child in health as well as the medical and surgical aspects of disease in children.

Edinburgh Royal Hospital for Mental Disorders

The 500 beds in this hospital are available for the clinical instruction of members of the university class of psychiatry. Clinical lectures on the chief forms of Mental Disease and Defect are given in the hospital and at the Jordanburn Nerve Hospital and the National Hospital for the Training of Imbecile Children, Larbert. A mental out-patient clinic is also conducted at the Royal Infirmary and students have the opportunity of coming into personal contact with and examining cases. There are resident physicianships and unqualified clinical clerkships in the hospital and a well-equipped laboratory under a bacteriologist is available for the prosecution of clinical research by those holding these appointments.

Edinburgh City Hospital

This hospital has 600 beds for Infectious Diseases. Clinical instruction is given by the university lecturer during each of the three terms of the academic year. In the course special attention is directed to methods of prophylaxis and every opportunity is taken to demonstrate the clinical manifestations of the various diseases at the bedside. Students attend the course in their fourth year after having passed the examinations in Pathology, Bacteriology, Materia Medica, and Therapeutics, and attended courses in Clinical Medicine and Clinical Surgery.

Edinburgh Royal Maternity Hospital

The hospital is situated close to the Royal Infirmary and the University Medical School. Here Midwifery is studied clinically, instruction being given by the professor of midwifery and the other physicians and assistant physicians who are university lecturers on clinical obstetrics. In addition to clinics and demonstrations members of the class are expected to follow all the work of the hospital, including the antenatal department. Before he can qualify for a certificate in the subject each student must reside for a period of at least five weeks in a University Hostel close to the hospital so that he can obtain full advantage of practical instruction on abnormal cases.

Post-graduate Instruction.—In the Departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for approved candidates for the degree of Ph.D. In connexion with the University and Royal Colleges post-graduate instruction is given during each of the three terms of the academic year as well as the summer vacation. In addition to a four weeks' General Surgical Course and a General Practitioners' Course of similar duration in August–September, special courses in Obstetrics and Gynæcology, Diseases of Blood, Endocrinology, Diseases of Nervous System, Urology, Ultra-violet Radiations, Interpretation and Significance of Modern Diagnostic Methods, &c., may be given during July to September. Particulars of these and other courses may be had on application to the Honorary Secretary, Post-graduate Courses in Medicine. Graduates may, if desired, attend the General Surgical Course or the General Practitioners' Course for a period of two weeks at a reduced fee. The University of Edinburgh is especially rich in Scholarships and Prizes in medical subjects. Full particulars concerning these, as well as concerning the fees at different stages, can be obtained from the Dean of the Medical Faculty.

UNIVERSITY OF GLASGOW

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: *M.B.* and *Ch.B.* (always conjointly), *M.D.* and *Ch.M.*; *B.Sc.* in Public Health; *D.Sc.* in Public Health; *B.Sc.* in Pharmacy; and *Ph.D.* in the Faculty of Medicine. A Diploma in Public Health (*D.P.H.*) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must attend a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses: Chemistry (including Organic Chemistry), with Practical Chemistry, three terms; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine with nine months more of general hospital practice; the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects: Ophthalmology, Diseases of the Ear, Throat, and Nose, Venereal Diseases, Tuberculosis, Fevers, Vaccination. The final year consists of three intensive terms of study: one devoted to Midwifery and Diseases of Women, one to Surgery, and one to Medicine.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry;

the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are granted to candidates, not under 24 years of age, who have previously obtained the double bachelorship, on submitting an approved thesis and completing examinations in Clinical Medicine for M.D., and in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M. The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College, and must prosecute a course of special study or research for two or three years and give evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject matter of the thesis.

Post-graduate Medical Teaching is available under the auspices of Glasgow Post-Graduate Medical Association, which is representative of practically all the Teaching Institutions in Glasgow. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. Arrangements have been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year.

There are many Bursaries, Scholarships, and Prizes in connexion with the Medical Course.

Anderson College of Medicine

Courses are given at Dumbarton-road, Glasgow, W., qualify for all the licensing boards and for niversities of Oxford, Cambridge, London, rgh, and Glasgow (the latter two under certain ons). Extensive *accommodation is provided* actical anatomy, chemistry, *botany, zoology,* iology, pharmacy, and operative surgery. Women dents are admitted *on the same terms as men,* d the Carnegie Trust *extends its benefactions to* tudents of the College. *Candidates for the* L.D.S. can obtain the full medical curriculum; the courses special to dentistry are conducted at the Dental Hospital, Glasgow.

Clinical Studies are carried on at the GLASGOW ROYAL INFIRMARY, the GLASGOW WESTERN INFIRMARY, the VICTORIA INFIRMARY, and other general hospitals in the city. Facilities for the study of special branches are afforded by the Royal Hospital for Sick Children, the Royal Mental Hospital, Hawkshead Asylum, the City Fever Hospitals, the Royal Maternity Hospital, the Samaritan Hospital, the Eye Infirmary, and the Bridge of Weir Sanatorium.

The following are additional centres of instruction:—

Glasgow Western Infirmary

This hospital of 650 beds adjoins the University. Special wards are set apart for diseases of women, throat, nose, and ear, and for affections of the skin. In the out-patient department there are special clinics for diseases of women and for diseases of the throat, ear, nose, teeth, skin, venereal disease, and electrotherapeutics. This is one of the radium centres for Glasgow and the West of Scotland. The clinical courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. In the pathological and bacteriological departments the courses are both systematic and practical, and extend through the winter and following summer; these are likewise recognised by the University for graduation. In addition post-graduate courses are held. Eighteen resident assistants are appointed annually from those who have completed their course. In the Clinical Laboratory students receive laboratory instruction from the lecturer on clinical methods. A new Ophthalmological Department is being erected where special courses will be held.

Glasgow Royal Infirmary

The Glasgow Royal Infirmary is the oldest and largest voluntary hospital in Glasgow. It is situated in the east-end of the city, adjacent to St. Mungo's Medical College, and contains 771 beds, although the daily average number of patients resident in the Infirmary during 1934 was 830. It is a general hospital with 22 wards devoted to general surgery and 10 wards to medicine. The special departments include wards for the treatment of burns, diseases of the ear, nose, and throat, skin diseases, diseases peculiar to women, urological diseases. There are also wards for metabolic examinations and treatment by oxygen therapy. The medical electrical department contains the latest plant, and treatment by electricity, light, &c., and electrocardiographic examinations are also carried out here. The Infirmary is a national radium centre, and has both national radium and radium belonging to itself for the treatment of cases of malignant disease and such other conditions as demand radiation. The orthopædic department includes a large massage department and school of massage for male students. There are also vaccination, dental, and nervous and mental diseases clinics, although beds are not provided for the special use of these clinics. The pathological institute comprises a large pathological block, bacteriological and biochemical departments, and a fully stocked pathological museum.

The Royal Infirmary is a large teaching hospital, recognised by the University of Glasgow and the Royal Faculty of Physicians and Surgeons of Glasgow. The teaching staff includes four professors—namely, of surgery, medicine, pathology, and diseases of women—who hold chairs in the University of Glasgow; nine lecturers appointed by the University; four honorary clinical lecturers in clinical medicine; five honorary clinical lecturers in clinical surgery (all appointed by the University); and numerous assistants to various departments. There are also Hall Fellows specially appointed, who act as clinical tutors. Full facilities are given to medical students for instruction in systematic clinical medicine and surgery, pathology, diseases of women, laryngology, rhinology, otology, &c. There is a very large out-patient department, where there are nearly half a million attendances of patients annually, and facilities are given to students for instruction in the various out-patient clinics and departments. The ophthalmic work is carried on at the ophthalmic institution, containing 36 beds (the institution being under the management of the Infirmary). Facilities are given for medical students to work here, and classes are held qualifying students in ophthalmology, required by the curriculum for the final examinations. Post-graduate classes are also conducted at the Infirmary and the Institution, and post-graduate clinical assistantships are available for a limited number of students.

Fifteen resident surgeons and physicians, who must be registered medical practitioners, are appointed by the managers of the Infirmary every six months, and fourteen non-resident surgeons and physicians are also appointed for the same period. Further appointments in special diseases are open to these resident and non-resident physicians and surgeons.

St. Mungo's College

The classes in St. Mungo's College (vide Glasgow Royal Infirmary) qualify for the medical and dental qualifications of the English, Scotch, and Irish Conjoint Boards, and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. Further particulars can be obtained from the Secretary of the Medical Faculty.

Victoria Infirmary

This institution, situated at Langside, and having its office at 40, St. Vincent-place, Glasgow, has 477 beds, and is the third of the extensive general hospitals in Glasgow to afford opportunity for clinical instruction to students. In addition to a full general staff there is a clinical research laboratory with pathologists and bacteriologists attached; radiological instructor, and a full staff of specialists. The Bellahouston Dispensary, also with a clinical staff, is conducted in connexion with the Victoria Infirmary. The Paying Patients' Wing has been extended and now has accommodation for 80 patients.

Royal Hospital for Sick Children, Glasgow

This institution consists of: (1) a hospital at Yorkhill containing 275 cots, built on an elevated and central site close to the University; (2) an out-patient department in West Graham-street; and (3) a country branch at Drumchapel, Dumbartonshire, containing 80 cots. There are one professorship and four lectureships in the University of Glasgow in connexion with the hospital, one professorship and one lectureship on the medical diseases of infancy and childhood, one lectureship on surgery and orthopædics in relation to infancy and childhood, one lectureship on biochemistry in relation to infancy and childhood, and one research lectureship on the pathology of the diseases of infancy and childhood. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition, special facilities are given for post-graduate study. Resident house physicians and surgeons are appointed every six months, in April and October.

Glasgow Royal Maternity and Women's Hospital

The average number of patients in the hospital at Rottenrow is 164. There are also over 4000 mothers attended per annum in their own homes. The work of the antenatal wards with their 50 beds is supplemented by large antenatal clinics where over 5000 new patients are seen in the course of the year. Well-equipped research laboratories were opened in 1926. A full-time Director of Research has been appointed. A pædiatrician gives daily attendance and the practice of the hospital affords a good field for post-graduate study.

Glasgow Royal Samaritan Hospital for Women

The hospital has 160 beds and offers excellent facilities for clinical instruction in the diseases peculiar to women. A new Radiological Department with the most modern apparatus for treatment was recently opened. Lectures and clinical demonstrations are given by members of the surgical staff. There is a complete course each University term for University students and one course in the summer term for College students. A post-graduate course is held during the summer months and a series of demonstrations for general practitioners is carried out in the winter. The hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for coördinating post-graduate medical teaching. The Royal Samaritan Lectureship in Gynæcology is a University Lectureship associated with the hospital.

Glasgow Lock Hospital

The hospital at 41, Rottenrow, Glasgow, founded in 1807, contains 84 beds and 16 cots for the treatment of females suffering from Venereal Diseases. There is also a Labour Ward, and a well-equipped Dispensary for out-patient attendances. There is a bacteriological laboratory, equipped with modern appliances, where continuous research work is done. Large University classes are held on the subject of female venereal disease. Post-graduate classes are also held. Recently the hospital has been completely renovated and modernised.

Glasgow Eye Infirmary

The wards and dispensary at Berkeley-street and Charlotte-street are recognised by the University for the purpose of instruction in ophthalmology for graduation in medicine at the University. A venereal centre has been established, and a branch dispensary has been opened in Clydebank. Post-graduate classes are held.

Glasgow Ear, Nose and Throat Hospital

The hospital contains 57 beds. At out-patient and indoor departments at 306, St. Vincent-street, clinical instruction is given. A research department has been installed and post-graduate courses are held during the year. Recognised by the University as a teaching school in Diseases of the Throat, Nose, and Ear.

Queen Margaret College*

Queen Margaret College (Women's Department of the University) is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. The school of medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. The women students attend classes in the various University Buildings at Gilmorehill, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Facilities for clinical work are given in the Royal, Western, and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine, and women are admitted to certain University bursaries and fellowships.

UNIVERSITY OF ST. ANDREWS

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews (United College, St. Andrews, and University College, Dundee)—viz., *M.B.*, *Ch.B.*, *M.D.*, *Ch.M.*, a Diploma in Public Health, Diploma in Dental Surgery (*L.D.S.*), and a Diploma in Public Dentistry (*D.P.D.*).

The extent and standard of the Preliminary Examination is determined by the Scottish Universities Entrance Board, constituted under Ordinance No. 70 of the Scottish University Courts (General No. 3—Regulations as to Admission to the Scottish Universities for purposes of graduation), in accordance with the terms of that Ordinance. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities exempts. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science.

---

* No returns.

Dr. Robert Heilig Library
S. M. S. Medical College

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz., Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology. Bacteriology, Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere with not fewer than 80 patients, with a distinct staff of physicians and surgeons, and recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, *Children's Diseases, Fevers,* Ophthalmology, *Diseases* of the Ear, Throat, and Nose, Anæsthetics, Dermatology, Venereal Diseases, Tuberculosis, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the *following regulations shall have effect: 1. Two of* the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine.

Part or whole of the medical curriculum of St. Andrews University must be taken at *University College, Dundee.* Provision is made by St. Andrews University for instruction in the work of the first two years, including Anatomy and Physiology, in both St. Andrews and Dundee. The last three years of the curriculum must be taken in Dundee in the medical school.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

Dundee Royal Infirmary

This institution has 450 beds. In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose, and Throat, and of the Skin; and for Pathology, Radiology, Electrotherapeusis, and Electrocardiography. The Pathological Department has recently been reconstructed and enlarged. Clinical teaching is given to students by the Honorary Staff; post-mortem examinations are conducted by the Pathologist. All courses of instruction are recognised by the University of St. Andrews and the other Universities and Boards of the United Kingdom. Ten Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons, and Students are appointed as assistants in the pathological department. Post-graduate classes dealing with General Medicine and Surgery, Midwifery, and other Special branches are held in May and June.

Post-graduate courses are given in connexion with the Dundee Royal Infirmary during the spring and summer months.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS

CONJOINT EXAMINING BOARD

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three bodies. This is the Scottish Conjoint Board. The three bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery.

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are *all those institutions* which feed the medical faculties of the universities, as well as all the places which are recognised by the *English and Irish* Conjoint Boards.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, 1 term; Elementary Biology, 2 terms; Elementary Inorganic and Organic Chemistry, 2 terms; Anatomy Lectures, 2 terms; Practical Anatomy, 5 terms; Physiology Lectures, 2 terms; Practical Physiology (including Histology, Biochemistry, and Biophysics), 3 terms; Materia Medica and Practical Pharmacy, 2 terms; Pathology (including Practical Pathology), 3 terms; Practice of Medicine, 2 terms; Clinical Medicine, 3 terms; Principles and Practice of Surgery, 2 terms; Clinical Surgery, 3 terms; Midwifery and Gynæcology, 2 terms; Diseases of Children, 1 term; Medical Jurisprudence, 1 term; and Public Health, 1 term. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than nine months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for three months the practice of a public dispensary especially recognised by any of the above authorities, and three months' attendance *at* the out-patient department of a recognised general hospital. This attendance should be made after the student has passed the First and Second Examinations.

Candidates are also required to attend the following three-monthly courses: *Diseases and Injuries* of the Eye; Insanity; Infectious Diseases; Gynæcology; Tuberculosis; Diseases of the Skin; Diseases of the *Ear, Nose, and Throat*; Radiology; *Orthopædics*; Diseases of Children. The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Systematic and Practical Biology, Chemistry, and Physics.

The Second Examination must be Written, Practical, and Oral, and consist of the following subjects: (1) Anatomy and Embryology, and (2) Physiology, including Histology (if not included in Anatomy), Biochemistry, and Biophysics. Candidates may be admitted to this Examination on production of the necessary certificates of curriculum.

The *Third Examination* must be Written, Practical, and Oral, and consist of the following subjects: (1) Pathology, including Bacteriology and Morbid Anatomy, and (2) Pharmacology (Theoretical and Practical), in- [illegible] istry, the Principles of [illegible] Writing. Candidates [illegible] amination on production of the necessary certificates of curriculum.

The *Final Examination* must consist of the following subjects[1]: (1) Medicine, including Therapeutics, Applied Anatomy and Physiology, and Clinical Pathology with Practical Medicine; (2) Surgery, including applied Anatomy and Physiology, Clinical Pathology, with Practical Surgery; (3) Midwifery and Diseases of Women, Clinical Obstetrics and Gynæcology, with Practical Midwifery; and (4) Medical Jurisprudence and Public Health. Medicine, Surgery, and Midwifery must be taken together, and Medical Jurisprudence and Public Health, and not earlier than on the conclusion of five Winters and five Summers of Medical Study, provided that a period of 33 months has elapsed since passing the Second Professional Examination. The Schedule for the Final Examination must contain a summary of the entire Course of Study, and, properly attested or proved by Certificates, must be lodged with the Inspector, and the fee paid, not later than two weeks before the examination. At the same time there must be produced a Certificate to show that the Candidate is not less than 21 years of age. No Candidate can be exempted from examination on any subject of the Final Examination unless he has already passed in the subject at this Board.

In addition to the Written and Oral Examinations all Candidates must be subjected to Clinical Examinations in Medicine, Surgery, and Midwifery and Gynæcology, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope and of other instruments, Clinical Chemistry, Surgical Appliances, Bandaging, Surface markings, Skiagrams, &c. The Oral Examination includes the recognition of specimens. All Candidates for the Final Examination must complete the three portions (Medicine, Surgery, and Midwifery) within a period of 19 months.

There are four periods of examination annually.

The Registrar in Edinburgh is Mr. David Thomson, 18, Nicolson-street; and the Registrar in Glasgow, Mr. David Willox, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained.

School of Medicine of the Royal Colleges, Edinburgh

The Lectures in this School qualify for graduation at Edinburgh and other Universities, for the Examinations of the Conjoint Boards of Edinburgh and Glasgow, London and Dublin. The number of students attending varies from year to year, and in recent years the average number has been about 600. In accordance with the Regulations of the University of Edinburgh one-half of the qualifying classes required for graduation there may be attended in this School, the fees paid for such classes being the same as those for the corresponding University classes. Special classes of instruction for
Dental students are conducted in the Scl
graduate courses are conducted in conju
the University. Further particulars re
School, also its calendar (price 9*d*., includi
may be had on application to the Dean of
Surgeons Hall, Edinburgh.

ROYAL COLLEGE OF PHYSICIA EDINBURGH

In addition to the Diplomas granted by
Conjoint Board, the Royal College of
grants its Single Licence to candidates w
are already on the Medical Register.

The Royal College of Physicians of
grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must
tiate of a British or Irish College of Phy
graduate in medicine of a University, a
the Council, and 24 years of age, is e
medicine, therapeutics, and in any bra
departments of medicine specially prof
as general pathology, psychology, pul

[1] Candidates at the Final Examination may be examined on Diseases of Children, Fevers, Tuberculosis, Insanity, Skin Diseases, Diseases and Injuries of the Eye, Diseases of the Ear, Throat, and Nose, Radiology, Venereal Diseases, Orthopædics, Vaccination, and Anæsthetics.

MEDICAL EXAMINING BODIES AND SCHOOLS IN IRELAND

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC)

Matriculation.—University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary: Extern Students, any examination recognised by the General Medical Council.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in July. Courses in preparation for it may be taken in the School of Physic.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended: (1) Botany, Zoology, Physics, and Chemistry; Descriptive and Applied Anatomy; Histology, Physiology and Applied Physiology; Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Practice of Medicine; Surgery; Midwifery and Gynæcology. (2) Three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital. (3) Practical Vaccination, one month's instruction. (4) Mental Disease, three months. (5) Practical Midwifery with Clinical Lectures, including Antenatal and Infant Hygiene Clinics, also not less than 20 personally conducted cases, five months, one of which must be as a resident intern student. (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. Intermediate Medical, Part I., including Anatomy and Physiology, Biochemistry and Histology; Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine, Hygiene, Jurisprudence, and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year, and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.— A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing, and must produce evidence of having been engaged in the study or practice of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination. The minimum time required for the complete course is nine months.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Scholarships and Prizes.—1. Medical and Surgical Travelling Prizes, £100, awarded in alternate years. 2. Bicentenary Memorial Prize, £30, awarded yearly, and given to the Travelling Prizeman. 3. Sir John Banks Prize and Medal. 4. Edward Hallaran Bennett Prize and Medal. 5. FitzPatrick Scholarship, awarded on results of Final Examination (interest on £1000). 6. Medical Scholarship, £20 per annum for two years, awarded in Chemistry, Physics, Botany, and Zoology. 7. Medical Scholarship in Anatomy and Physiology, £20 per annum for two years. 8. Henry Hutchinson Stewart Scholarships, one in Botany, Zoology, Chemistry, and Physics, and another in Anatomy and Physiology, awarded annually and valued at £10 per annum for three years. 9. Henry Hutchinson Stewart Scholarship in Mental Diseases, awarded from time to time, £50 per annum for three years. 10. John Mallet Purser Medal, awarded annually in Physiology. 11. Daniel John Cunningham Medal and Prize, awarded annually in Anatomy. 12. Begley Studentship, £40 per annum for four years, awarded annually. 13. Kingsmill Jones Memorial Prize, awarded annually in Natural and Experimental Science, £15. 14. O'Sullivan Memorial Scholarship, £48, awarded annually for excellency of record in school. 15. Adrian Stokes Memorial Fellowship, awarded every second year, the holder to carry out original work in Pathology and Bacteriology, about £320. 16. Aquilla Smith Prize, awarded annually in the Final Medical Examination, Part I., about £10. 17. Walter G. Smith Prize, awarded annually in Materia Medica and Therapeutics, about £10. 18. De Renzy Centenary Prize in Public Health, awarded annually, £15. 19. Connolly Norman Medal in Mental Diseases.

Post-graduate Instruction.—Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept. 16th, to Saturday, Oct. 5th. Women graduates can be accommodated at Trinity Hall.

NATIONAL UNIVERSITY OF IRELAND

Matriculation.—All students must pass a matriculation examination; the examination taking place in June and September in Dublin, and at certain local centres, includes five subjects, three of which must be Irish, English, and mathematics. All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination: (1) Irish. (2) Latin. (3) Greek. (4) French. (5) German. (6) Italian. (7) Spanish. (8) Portuguese. (9) Welsh, or any other modern language approved by the Senate. (10) English. (11) Mathematics. (12) History. (13) Geography. (14) Applied Mathematics, or Physics as an alternative. (15) Chemistry. (16) Botany. (17) Agricultural Science. (18) Commerce. (19) Music, and for women candidates only (20) Physiology and Hygiene. Students entering for degrees in Medicine or Dentistry, if not already registered by the General Medical Council, must take Irish, Latin, English, Mathematics, and a fifth subject.

The medical degrees granted are:—

M.B., B.Ch.; B.A.O.; M.D., M.Ch., M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, 49, Merrion-square, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

University College, Dublin

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland. The pre-registration examination in physics and chemistry is taken after matriculation either at the beginning of or during the winter session. The course is of five years' duration and dates from the passing of the pre-registration examination.

Degrees of M.B., B.Ch., and B.A.O.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination (Part I.) includes Pathology, Materia Medica, Pharmacology, and Therapeutics. Part II. (Third Examination), taken at the end of the Fourth Winter Session, includes Hygiene and Medical Jurisprudence.

The Final Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year after registration, when the curriculum has been completed. The degree of M.D. may be obtained either by examination or on published work.

The D.P.H. Course extends over the year, beginning at the opening of the session.

University College, Cork

In the School of Medicine students must have passed the Matriculation Examination of the University or some other recognised examination, and a preliminary examination recognised by the General Medical Council.

Medical Students who have passed the First Professional Examination of the Conjoint Boards of Ireland, England, or Scotland may be admitted to the rank of second-year students on making application to the Council. Similarly, students who have passed the Second Professional Examination of the same Boards may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may rank as fourth-year.

The school is provided with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical, and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are dissecting-rooms, well-appointed physical, chemical, and biological laboratories, a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings.

Clinical Instruction.—Students may attend the South Charitable Infirmary and County of Cork General Hospital, Cork North Charitable Infirmary and City of Cork General Hospital, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, Bon Secours, Fever, the District, and Ear, Eye, and Throat Hospitals. Candidates are prepared for D.P.H.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, and in respect of the hospitals from the Secretaries.

Residence of Students.—Students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, and register their addresses each session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students. There are Students' Clubs for men and women students of the College and various athletic clubs.

University College, Galway

The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. In the School of Medicine there are 12 Entrance Scholarships, varying in value from £30 to £60 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value from £30 to £40 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological and Medical Society. There are facilities for research and Post-graduate work in the Chemistry, Physiology, Pathology, and Anatomy departments. There are ample facilities for Women Students.

Clinical Instruction is given in the Galway Central Hospital and in the Galway Tuberculosis and Fever Hospitals. The CENTRAL HOSPITAL (300 beds) is completely renovated. In addition to the surgical and medical departments, there are now eye and ear, throat and nose, gynæcological and obstetrical, pathological, X ray, electrical and massage departments. Medical and Surgical Clinics are held on alternate days during term. Two Resident Physicians and two Resident Surgeons are appointed every six months. Resident Students are admitted. The hospital is open to qualified medical men for post-graduate work.

HOSPITALS AFFORDING RECOGNISED PRACTICE [1]

The following hospitals afford practice recognised by the Irish Universities and Corporation. Further information can be obtained from the respective secretaries.

Sir Patrick Dun's Hospital

Classes both in Medicine and Surgery are held each morning at Grand Canal-street, Dublin, from 9 o'clock from the beginning of October till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A resident surgeon and resident physician, with salaries, are appointed annually. Six resident pupils are appointed every six months. Twelve surgical dressers and twelve clinical clerks are appointed each month. There are facilities for women students.

The practice of the hospital is open to all students, and the certificates are recognised by Dublin University, the National University, and Royal Colleges of Surgeons of England; Ireland, and Scotland. It is an official "Treatment Centre" for venereal diseases.

At the end of last year an out-patient department was fully equipped. It has medical, surgical, gynæcological, ear, nose and throat departments, and an accident department, with theatre and dressing dispensary. A valuable asset to the teaching responsibilities of the institution has thus been added.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in medicine and in surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in medicine and surgery provided they show sufficient merit.

Adelaide Hospital

Two resident surgeons and four or more resident pupils are elected every six months.

Prizes.—The Hudson Scholarship, £30 and a Gold Medal, as well as the Hudson Prize, £10 and a Silver Medal, are awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology. In addition to this prizes are awarded in gynæcology and dermatology, and in clinical medicine and surgery for junior students. Wallace Beatty Memorial Bursaries are granted at the discretion of the Medical Board at the beginning of the Winter session. The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Post-graduate work in the hospital is in conjunction with the course in Trinity College.

Mater Misericordiæ Hospital

This hospital, under the care of the Sisters of Mercy, containing 300 beds and 96 private beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the staff. Ophthalmic surgery and surgery of the nose and throat are taught in the special wards and in the dispensary. Surgical operations are performed daily. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general medical, dermatological, surgical diseases, and accidents: a fully equipped biochemical laboratory, a modern electro-massage department, an electrocardiograph room, and radiological department. Instruction is given on pathology and bacteriology. Four house physicians, eight house surgeons, and 18 resident pupils are elected annually. Dressers and Clinical clerks are appointed regularly and certificates given for merit. Leonard Prizes will be offered for competition annually. Certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. There is a private hospital for the reception of medical and surgical cases. A training school and a home for trained nurses are connected with the hospital, and nurses who have passed a qualifying examination can be obtained on application to the Lady Superioress. Entries can be made with any of the physicians or surgeons or with the Registrar, 8, Fitzwilliam-place, Dublin.

Mercer's Hospital

This hospital, situated in the centre of the city of Dublin, is in closest proximity to the Medical Schools, any of which can be reached on foot within five minutes, and from its position receives a large number of cases of emergency surgery in addition to the ordinary medical and surgical practice. Extensive alterations and reconstruction have brought the wards up to date. Additions have been made in the radiographic and electrocardiographic departments. Classes for pupils are held on alternate mornings in the medical and surgical wards. There is a large out-patient department available for the teaching of medicine, surgery, and gynæcology. Arrangements for clinical instruction are made with Cork-street Fever Hospital. A gold medal is awarded annually to the best pupil on the books of the hospital, and an annual prize of £25 has been added. A house surgeon and a house physician are appointed annually, and there is residential accommodation for six men and two women pupils. Clinical clerks and dressers are appointed from the classes.

Richmond, Whitworth, and Hardwicke Hospitals *

These House of Industry hospitals, North Brunswick-street, Dublin, contain 325 beds—140 for surgical cases, 75 for medical cases, 78 for fever and other epidemic diseases, and an auxiliary wing with 32 beds, devoted mainly to throat, nose and ear, and skin diseases. Three resident physicians and three resident surgeons are appointed each half year. Resident clinical clerks are appointed each quarter, and it has always been the aim of the Medical Board to ensure that each student spends at least six months in residence. In addition, junior students are appointed as extern clinical clerks and surgical dressers. Women students are eligible on the same terms as men. Ample facilities exist for post-graduate work in the various special departments, as well as in general medicine and surgery. Extensive alterations and improvements have recently been made in the X ray, electrotherapeutic, and electrocardiographic departments. Two open-air huts to accommodate ten patients have been erected in the spacious Whitworth grounds. A new students' residency has been opened. This contains facilities for 20 male and 8 female resident students.

Royal City of Dublin Hospital

The hospital contains 160 beds and a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. There is a large nursery where special opportunities are afforded for the study of diseases of children, both medical and surgical. There are also special wards for ophthalmic, aural, and gynæcological cases; also a department for the Erlangen Treatment by deep therapy. There is a largely attended out-patient department, where students are allowed to attend accidents and dress cases under supervision. Six resident pupils are appointed every three months. A house surgeon and a house physician are appointed annually.

Dr. Steevens' Hospital

This hospital, at Dublin (Kingsbridge), contains 180 beds. There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate. There is an electric massage department, a "sun-ray" and diathermy department, and an X ray department. There are also two V.D. wards and a largely attended V.D. treatment centre, as well as a large ward reconstructed and re-equipped and opened as open-air ward for tuberculous and other diseases of bone (25 beds) for females, two open-air verandahs for male surgical tubercular cases (14 beds), and children's ward (12 cots). Information as to terms for residency can be had from the Resident Surgeon at the Hospital.

---

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described. The secretaries of the hospitals will always be ready to answer inquiries or to give additional information.

* No returns.

Meath Hospital and County Dublin Infirmary

The hospital contains 150 beds, available for clinical teaching, both medical and surgical. There is a separate fever block which contains 40 beds. A special ward has been set apart for the reception of children. Special departments are as follows: Ear, Nose, and Throat, Dental, Diseases of Women, Skin, and Genito-urinary System. Clinical Teaching includes classes for both Senior and Junior Students. The Joseph Smyth Scholarship in Medicine, value £50, is awarded biannually. Gold and Silver Medals are given annually to the best answers in an examination in Clinical Medicine and Surgery. Prizes are also awarded to the Junior classes at the Sessional Examination. Two House Surgeons, a Resident Casualty Officer, and a House Physician are selected each half-year from fully qualified pupils of the hospital. A new students' quarters has recently been erected. The Meath Hospital is within a few minutes' walk of the University of Dublin, the Royal College of Surgeons, and The National University.

Jervis-street Hospital, Dublin *

This hospital contains 120 beds. Eight resident medical officers are appointed each year and facility is thus given to past students of the hospital to acquire experience as house surgeons. Resident students are provided with apartments, fuel, and light, free of charge. Arrangements have been made by which students of the hospital can have special fever training in Cork-street Fever Hospital, free of charge.

St. Vincent's Hospital and Dispensary

This hospital has 200 beds. Clinical lectures in medicine and surgery are held from October to June. Special classes for juniors from October to December. Pathological and bacteriological demonstrations are given every Thursday, and instructions in the use of laryngoscope and otoscope for senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Ferrall gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the McArdle Memorial Prize, value £20. There are a large extern department and a new pathological laboratory. A new electrocardiographic department has been installed.

Rotunda Hospital

The Rotunda Hospital, Dublin, is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually, and upwards of 1000 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year, and consists of daily clinical instruction in the maternity department, and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. They also assist in rotation at gynæcological operations, and if staying more than two months are personally allowed to perform some minor ones. An antenatal dispensary is held three times weekly and all students are encouraged to attend. A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master. In addition there is a special class in operative obstetrics, limited in number. The pathological laboratory is under the supervision of a skilled pathologist, who gives special classes at intervals. A Biochemist has just been appointed who is carrying out the Aschheim-Zondek test for pregnancy, and who is prepared to help any Post-graduates who are keen on doing research work on the material in the hospital. There is a fully equipped X ray installation under the care of a competent radiologist. A ward has been opened for the treatment of infantile conditions, and is under the care of a pædiatrician, who gives instruction in the out-patient department, which is held daily. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M., and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. Board and residence can be obtained in the hospital. One grass and two hard tennis courts and one standard squash racquet court are available for students in the residents' mess. The L.M. certificate is given to qualified practitioners on examination after six months' attendance at the hospital (four months in the case of those who took their midwifery training in the hospital). Fees: one month, £6 6s.; months other than first, £4 4s.; three months, £12 12s. L.M. course £21. Full particulars from Andrew H. Davidson, M.D., Master, Rotunda Hospital.

Coombe Lying-in Hospital

The Coombe Lying-in Hospital and Guinness Dispensary for the Treatment of Diseases peculiar to Women, Dublin, contains 70 beds, and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The hospital gives to men and women students and post-graduates a thorough training in obstetrics and gynæcology. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a large general dispensary, held daily, at which instruction is given on the diseases of women and children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this dispensary, or at the prenatal clinic, held on three evenings a week, at which there are about 3000 attendances annually. Every year about 1200 women are delivered in the hospital and about 1500 on the district. There is accommodation for intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Women students can reside in the hospital. Clinical assistants are appointed from amongst the post-graduates as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Students can attend at any time. Plans for a new hospital of 136 beds, and a new residency for students, are now complete, and the building operations will begin in the near future.

National Maternity Hospital

This hospital at Holles-street, Dublin, is now in full working order. It has 80 beds and comprises intern and extern maternity, gynæcological wards, and a dispensary for the treatment of diseases of women, an infant clinic, and an antenatal and postnatal branch. The postnatal instruction is given three times a week. Every facility is given for the carrying out of practical work, and modern equipment provides full facility for the treatment of both maternity and gynæcological patients. Undergraduate and post-graduate courses are arranged at any time and clinical instruction is given daily and oral lectures four times a week. Certificates of attendance at this hospital are recognised by all the licensing bodies. The L.M. Diploma is given by special examination, which is held four times a year. Total number of admissions last year 1882. The building of a final section of the hospital, containing 64 additional beds and a new out-patient department, is about to be begun.

* No returns.

QUEEN'S UNIVERSITY OF BELFAST

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health and a Diploma in Psychological Medicine, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission shall matriculate or fulfil such other test of fitness as may be prescribed by the Senate, or may be exempted from the matriculation examination by having passed similar examinations elsewhere.

For information as to Scholarships and Prizes, inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany, and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology, and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for Part I. of this examination at the close of the third year, and for Part II. at the end of the Winter Session of the fourth year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery and Gynæcology; (4) Ophthalmology and Otology. Candidates who have previously passed the Third Examination may present themselves for the Fourth Examination at the close of the fifth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination and on the clinical courses in the hospitals. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of Part I. of the Third Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The J. C. White laboratories are fully equipped for research in biochemistry. The Institute of Pathology, which is adjacent to the Royal Victoria, Royal Maternity, and Children's Hospital, provides fully equipped accommodation for Pathology and Bacteriology, including class-rooms, demonstration room, lecture theatre, library museum, and research laboratories. There is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the Corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, and the diagnosis of cases of infectious diseases. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Belfast Hospital for Sick Children, the Royal Maternity Infirmary and Hospital, the Ulster Hospital for Women and Children (56 beds), the Benn Ulster Eye, Ear, and Throat Hospital (30 beds), the Belfast Ophthalmic Hospital (30 beds), the City Fever Hospital, Purdysburn (360 beds), the Union Fever Hospital (200 beds), and the Belfast District Lunatic Asylum, where the Purdysburn Villa Colony has 1350 beds.

Further information can be obtained from the respective Secretaries.

Royal Victoria Hospital, Belfast

There are 430 beds. Students eligible for McGrath, McQuitty, Malcolm, Coutler Smyth, and Elwood Scholarships aggregate annual value £185. Twelve house surgeons and house physicians. Thirty-six resident pupilships, three months each, annually for senior students, of which a proportion is allotted to women students, special departments for radiology, clinical pathology, V.D., dermatology, gynæcology, [illegible] maternity, vaccine therapy, [illegible] dentistry, radium therapy. [illegible] and demonstrations are given on Wednesdays throughout the year with the exception of holiday seasons.

Mater Infirmorum Hospital, Belfast

This hospital contains 270 beds and is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given daily by Physicians and Surgeons. Surgical operations are performed daily. The out-patient departments in medicine and surgery, also the special dispensaries for gynæcology, ear, eye, and throat, electrotherapeutics, venereal diseases, varicose veins, and hæmorrhoids are very largely attended and afford valuable opportunities to students for the study of those subjects. There is a well-equipped electro-medical and massage department. A new extern has been erected beside the hospital on ground given by the Government of Northern Ireland. This will relieve the congestion of the old extern which in part is being converted into accommodation for resident students. A fine and extensive nurses' home has also been built in the vicinity of the hospital. There is also a dental dispensary. A house physician and two house surgeons are elected every six months. Resident pupils are admitted as the vacancies arise. Three Exhibitions and a Gold Medal are competed for annually in June. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom.

Belfast Hospital for Sick Children

At the hospital on Falls Road there are 75 beds, and clinical instruction is given. During the winter and summer sessions courses of lectures are delivered on the medical and surgical diseases incidental to infancy and childhood. Demonstrations in ophthalmology and pathology are given, and ample opportunities are afforded in the wards and in the out-patient department for gaining a practical and theoretical knowledge of the diseases of infancy and childhood. A department for conservative dentistry for small children has recently been equipped and is now in use. This hospital grants Certificates in Diseases of Children, which are recognised by the various examining bodies. Certificates are also granted for post-graduate study. A Gold Medal is offered for competition at the close of the session. A Davis Scholarship is awarded every two years for the best thesis on some branch of children's diseases.

Belfast Infirmary and Hospital

There are 1800 beds. Clinical courses are given quarterly, and a course for D.P.H. in hospital. An intern venereal clinic in infirmary is under the Corporation scheme. The maternity wards are recognised for practical midwifery training. The certificates of the vaccination class are recognised by the Local Government Board. There is a department for cancer with 32 beds, also X ray, bacteriological, and massage departments.

Royal Maternity Hospital, Belfast

This new building is in the grounds of the Royal Victoria Hospital and supersedes the maternity hospital in Townsend-street. There are 100 beds and an antenatal department catering for a large district. There is also an infant clinic and a separate septic block. The University obstetric tutor resides in the hospital and acts as senior resident medical officer. There are three house surgeons in addition, and resident accommodation for 15 resident students or post-graduates.

WE take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS

CONJOINT EXAMINING BOARD

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be completed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad. The first examination consists of Part I. (*a*) Biology, (*b*) Applied Chemistry and Physics; Part II., Anatomy and Physiology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics, (*c*) Forensic Medicine, Hygiene, and Public Health, (*d*) Ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Children, and the Practice of Vaccination.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Further information can be obtained from the Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The College issues its Licences in Medicine and in Midwifery to Medical Men whose names appear on the Registers of the General Medical Council or of Saorstat Eireann.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November.

The Fellowship.—Fellows are elected by ballot. An applicant must have been a Member of the College for at least one year and must have attained the age of 27 years.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The College issues its *Licence in Surgery* to practitioners whose names are entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he *presents himself for examination*, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Irish Conjoint Board.

Candidates are examined in General Surgery (paper and oral), Clinical Surgery, Surgical Pathology (oral), Operative Surgery, Surgical Anatomy (paper), and Ophthalmic and Aural Surgery (clinical).

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the *Final Examination* immediately after passing the *Primary part, provided they* have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical *Anatomy and Pathology. For admission to the Final* Examination the candidate must have passed the *Primary Examination, and must* be a Licentiate or Graduate in Surgery of a university or licensing body *recognised* by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars can be obtained from the Registrar of the College, Stephen's Green West, Dublin.

Schools of Surgery

The Schools of Surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They *are carried* on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological and bacteriological laboratories are fitted with the most approved appliances in order that students *may* have the advantage of the most modern methods of instruction. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s.*; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. *Prospectus and guide for medical students* can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's Green W., Dublin.

APOTHECARIES' HALL OF IRELAND

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the *necessary* examinations. The diploma of the Hall entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence.

Candidates must pass three Professional Examinations, called the First and Second Professional Examinations and the Final Examination, which are conducted at separate times, partly in writing and partly practically and orally. The Examinations are held thrice a year—viz., in March, June, and November, or such other dates as may be determined.

Candidates who produce satisfactory evidence of having passed an examination for a Degree or Licence in Medicine, *conducted by* any University or Royal College in the British Empire, or by any Foreign University whose Degrees are recognised in the Foreign List of the Medical Register, will be exempted from the *Primary Examination.*

The subjects for the First Professional Examination are: Anatomy, Physiology and Histology, *including* Biochemistry; and for the Second Professional, *Materia* Medica and Pharmacy, Pathology, and Medical Jurisprudence and Hygiene.

For the Final Examination the subjects are: (*a*) Medicine and Clinical Medicine and Clinical Methods. (*b*) Surgery—Clinical, Ophthalmic, and Operative; and Surgical Anatomy. (*c*) Midwifery and Gynæcology, and Practical Pharmacy and Materia Medica (*if not taken at Intermediate Examination*).

Each candidate before receiving his diploma must *produce evidence* that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied by the Registrar at 95, Merrion-square, Dublin.

PRISON MEDICAL SERVICE

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment *may* be *made on a special* form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. In the smaller prisons the medical officership is part-time, and is usually *filled* by *practitioners* in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case *of a whole-time service*, the appointment is in the first instance to the post of Medical Officer, Class II., and from this rank the Medical Officers, Class I., are selected as vacancies *occur*. The pay of the whole-time prison medical *staff is as* follows: Medical Officer Class II., £515 18*s.* a year, proceeding by annual increments to £738 12*s.* a year, the maximum being normally attainable after 10 years' approved service; Medical Officer, Class I., £797 3*s.* *a* year, proceeding by annual increments to £953 13*s.* a year, the maximum being normally attainable after 6 years' approved service. *Unfurnished quarters* are provided or an *allowance* in lieu is made. The *conditions of* service are liable to review. Study-leave is granted annually to two of the whole-time Medical Officers. There are 12 full-time medical officers of Class I. and 15 *Class* II. and 25 *part-time* medical officers. The *full-time posts* are pensionable. The number of vacancies is never large.

PHARMACEUTICAL SOCIETY

THE COLLEGE OF THE PHARMACEUTICAL SOCIETY is a constituent part of the University of London. The Society conducts *examinations* for registration as (*a*) Chemist and Druggist and (*b*) Pharmaceutical Chemist. Courses of Instruction are given for these examinations.

An Intercollegiate two years' course for the Final Examination for the degree of B.Pharm. of the University of London is also given. Medical students are admitted to the lectures and laboratory work. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates of approved Universities may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories; this degree may be taken in Pharmacy, Pharmacognosy, Pharmaceutical Chemistry, *and* Pharmacology. Several scholarships are also offered. Further information may be obtained from the Dean, 17, Bloomsbury-square, London.

THE LANCET

LONDON: SATURDAY, AUGUST 31, 1935

REFORM OF THE CURRICULUM

A CONSPECTUS of the courses in medical education which present themselves to the student at the various universities and colleges before a medical degree or diploma can be obtained is published in these columns every year; and every year the Students' Number of THE LANCET is on the surface much like its predecessor, as on the surface it may resemble its successor. But the progressive nature of the educational curriculum can be grasped in a moment if issues which have appeared at considerable intervals are looked at with the comparing eye, and it is likely that in the near future there will be changes to record, whose effect will be immediately perceived. But, judging by the past, such changes may take place before their results appear in any conspectus.

For several years, and latterly with increasing attention, the medical curriculum has been closely examined by persons with proper equipment and authority to report upon it. In 1933 the General Medical Council adopted some wise recommendations in regard to professional examinations in response to a generally expressed opinion from many of the educational centres that the absence of due continuity and sequence in medical study caused the results of examinations to give an unfair view of the work of the candidates. In the same year the Council of the British Medical Association appointed a committee on Medical Education with the reference to consider and report upon the pre-medical studies; the content of the curriculum and its arrangements; the nature of examinations or other tests to be satisfied; and lastly on the question whether post-graduate educational experience should be required prior to registration. This was a valuable report, contemplating no stereotyped system of medical education but seeking to raise the scientific status and educational equipment of entrants to the profession. The course designed was coördinated so as to avoid separate blocks of study, and a feature of the scheme was the insistence on a period of practical work after the main part of the final examination had been passed, before full licence to practise was granted. There was no suggestion for lengthening the curriculum.[1] Next, in the spring of this year there appeared the report, the result of a joint conference between representatives of the universities of London, Oxford, and Cambridge, of the English Royal Colleges, and of the Society of Apothecaries, and in many directions the same conclusions were arrived at. The conference recommended no changes which would prolong the present minimum period of five years' study before a medical qualification could be obtained and aimed at methods which would make of the road to qualification a continuous period of study as little broken up by examinations as possible, thus affording the students more time and opportunity for self-education. The conference was impressed by the high proportion of failures in examinations in anatomy and physiology, but it looked to alterations in modes of teaching rather than to any lowering of the standard to mitigate this trouble. In respect of post-graduate clinical experience the conference held that a medical student after passing the final examination should spend at least six months as a resident medical officer in an approved hospital before entering upon private practice, and thought that in the near future a sufficient number of posts for the purpose would be available.[2] Thirdly, in June of this year there appeared the report of the Special Committee of the General Medical Council on the revision of the medical curriculum. This was an admirably clear analysis of the existing course, agreeing with the main recommendations which had already been expressed not only in the two reports alluded to above, but, and with reiteration, in the columns of the *British Medical Journal* and *The Lancet.* The document confirmed the accuracy of much of the criticism, but included the cheering expression that by comparison with the standards of qualification prevailing in other countries the British system was good, while its development could be best advanced by reshaping it. Admitting that the General Medical Council has no power to make any requirements subsequent to the passing of qualifying examinations, the report of the Council registered the opinion that there were no grounds for lengthening the present period of the curriculum.[3]

All three reports are the outcome of a general impression, to which frequent voice has been given, that the curriculm requires reshaping, as is allowed in the report of the G.M.C. The student is compelled to acquire for examination purposes matter that is of little practical service to him—while we allow that all knowledge has value; the thread of continuity is not sufficiently maintained between the preclinical and clinical instruction; the multiplicity of examinations consequently bears hardly upon the student, while as the standard of preliminary education, speaking generally, is not high, for many students the tests become unduly difficult. The three reports have appeared in substance in the medical press so that there is now a perfect opportunity of understanding the situation and what experts think of it. The issue remains with the G.M.C., the standardising authority, which, though it has the responsibility of control and supervision, respects always the autonomy of the qualifying bodies. It would seem that it is at the beginning and at the end of the course that the real changes may be expected, though action must be influenced by the necessity for obtaining the common consent of the different centres concerned; and this may be a delicate matter when the standard of preliminary education is at issue. Registration of medical students is not mentioned in any of the Medical Acts and we understand can only be enforced by the G.M.C. if Parliamentary power or general consent of the qualifying bodies is obtained; yet for many reasons registration should be made compulsory. At the end of the curriculum the student having passed the necessary tests for admission to the Register should be given more opportunity to acquire practical knowledge. This is stated or implied in all the reports but there is no recommendation dealing expressly with the matter which is common to them all. As a corollary we publish this week the results of a limited investigation into the material prospects of certain newly qualified persons. The wish is to give a picture of how a group of entrants belonging to an early period of qualification have been able to use their training, as now given, to make good in the world. The results of the investigation thus have a pertinent bearing on any reforms in the curriculum now contemplated.

SPECIAL ARTICLES

THE PRESENT-DAY OPENINGS OF MEDICAL PRACTICE

"Good heavens, gentlemen, what is to become of you all?" was Mr. Abernethy's remark a hundred years ago to the students of St. Bartholomew's Hospital on the first day of a new session. And last month in his presidential address to the national health insurance section at the Royal Sanitary Institute health congress at Bournemouth, Mr. F. J. Webb pointed out the difficulties facing the present-day graduate in medicine. Competition, he said, was being steadily increased from two sources—namely, the overcrowding of the profession by the large number of students annually qualifying, and, secondly, the encroachment of the public health services upon the territory of the family doctor through municipal hospitals, infant welfare centres, and tuberculosis clinics. The latter influence, however hardly it may bear upon the general practitioner, does not, of course, necessarily reduce the graduate's prospects of employment; it may merely shift its centre of gravity. In his promoter's address [1] to Edinburgh medical graduates, delivered about the same time, Prof. R. W. Johnstone also expressed some anxiety about the increasing number of medical students and the greater number of graduates likely to come upon the Register in the next few years. Our export trade, he reminded his hearers, is not what it was; the Dominions are producing doctors of their own in increasing numbers ("not Scottish doctors, it is true, but still doctors"). But he was confident that the so-called law of supply and demand would rectify matters, although too keen competition might introduce into professional life a commercial spirit destructive of its best traditions. The first five years of practice would almost certainly be lean years financially; but, as his old chief used to say to him, there is nothing makes a man work like an empty stomach.

Prof. Johnstone pointed his remarks by giving an account of an inquiry he had made into the careers of Edinburgh graduates who had been at least 25 years in practice. His information was derived largely from the Medical Directory. Of 1445 men and women whose record he analysed he regarded 3 per cent. as having achieved distinguished success, 31 per cent. considerable success, and 55 per cent. a fair degree of success—refusing however to give away the basis of his classification. Of these 1445 men and women about 80 per cent. went into general practice, 13 per cent. into the regular imperial services (Army two-thirds), and just over 6 per cent. became whole-time medical officers (62 M.O.H.'s, 30 asylum superintendents). The proportion taking higher degrees since graduation were in percentages: M.D., 30; one or more of the higher diplomas, 26; fellowships of the royal colleges, 16. Of the 100 women 60 had married.

With such problems as these in mind it appeared to the Editor of THE LANCET that it would be of considerable value and interest to prospective candidates for a medical degree, if a special inquiry were made into the experience of a large sample of medical men and women who had graduated in a more recent year. For this purpose the graduates of 1930 were selected, and approached by means of a questionnaire.

METHOD OF INVESTIGATION

In the year 1930, 1490 men and women registered their names with the General Medical Council. Of this total it was found possible to identify 1477 in the Medical Register of 1935, and to each of these the questionnaire here reproduced (the entries, of course, are imaginary) was directed.

This questionnaire was sent out in the middle of June and the replies received up to the middle of August have been included in the analysis discussed in the succeeding sections. It must be noted that of these 1477 graduates there were 1163 resident (according to their registered addresses) in Great Britain and the Irish Free State, and 314 who had migrated (or returned) to other parts of the world—142 to India, 39 to South Africa, 31 to Australia and New Zealand, 15 to Canada, and the remainder in twos or threes to countries spread throughout the world. The time interval which had to be allowed between dispatch of the questionnaire and the analysis of the replies was insufficient to allow all the possible replies to be received from abroad, although actually nearly 100 replies bearing foreign or colonial stamps were received.

THE RESPONSE

The total number of replies (excluding 39 returned "present address unknown") amounted to 651, or 44 per cent. of the maximum. A response of nearly one-half must be regarded with satisfaction, since many inquiries by questionnaire fail to secure replies from more than 10 per cent. of those addressed. This relatively large response is without doubt due to two factors—namely, the exclusion of any clue to the identity of the correspondent and the careful simplification of the queries included on the form. Whether the 44 per cent. of the graduates who replied may fairly be regarded as a representative sample of the total addressed is an important question, but one to which it is impossible to give a certain answer. There might well be a tendency for those who have been successful in their profession to be more eager to register their success than those who have failed. Alternatively, the latter might under the veil of secrecy be glad of the opportunity (as appears in a few cases) of stating frankly the drawbacks of the profession they have, perhaps misguidedly, chosen, though those who have turned to other professions might tend not to reply. It is out of the question to determine whether indeed there are any such factors of importance influencing the determination to answer or not to answer. The difficulty is inherent in all investigations of this type, and the only conclusion is that a large sample of replies has been received, that there is no obvious or certain reason to lead one to believe that this sample is unrepresentative of the total, but, equally, there is no evidence that it *is* representative. With this proviso we pass to the analysis of the replies.

An Enquiry into the Present-day Openings of Medical Practice

The Editor of "The Lancet" to the Medical Graduates of 1930

In the Educational Number this year I am hoping to give medical aspirants and their parents some idea of the prospects in medicine under present-day conditions, and the best way of doing this with any completeness and accuracy would be to obtain the experience of a group of recent graduates. For this purpose the 1490 men and women who registered in the year 1930 have been selected. Will you help by filling in answers to the following questions and posting your reply without delay in the attached envelope?—*without adding name, address, or other clue to your identity.*

7, ADAM STREET, ADELPHI, W.C.2. *June*, 1935.

M ~~F~~ Age last birthday } 29 ~~married~~ single (please strike out what does not apply) But engaged

1. What branch of medicine have you taken up? *
(Mention any degree or diploma *taken since qualification.*)
M.B., B.S. Lond. General practice alone panel 1400

2. What led you to this choice? †
Preference for the clinical side of medicine and a desire to be my own master

It would add greatly to the value of these two replies if you would also answer the question—

3. What was your approximate income from professional work last year? ‡ £840

* *Branch of medicine.*—Please use one or more of the headings in the following list, adding explanatory details if needful.

General practice: alone, assistant or partner: size of own panel (if any).
Specialty: ? what.
Public health: ? which branch.
Services: ? which and present rank.
Hospital residency: ? voluntary or municipal.
Hon. hospital appointment: ? type of hospital.
Teaching appointment: ? what.
Research: ? what.

† *Choice.*—If you have discontinued medical work please say so.

‡ *Income.*—Please give gross earnings from professional work for the year ended April 5th, 1935, adding estimated value of maintenance allowance where a resident post is held.

AGE AND SEX

The 651 forms returned relate to 596 men and 55 women, a ratio of approximately 11 to 1. (A few, lacking information, were presumed to refer to males.) The ages lie mainly within narrow limits, for (measuring the percentages on those giving information on this point) it was found that 67 per cent. of the men and 70 per cent. of the women were of ages 27–30 inclusive. On the other hand, the range of ages recorded is very wide. Twenty-six years is the lowest in both sexes and, curiously, the highest in both sexes is fifty-three. It is not unlikely that a proportion at these older ages represent persons who graduated earlier in life but delayed registration, or persons of other nationalities who obtained a British qualification in 1930. This is so in at least six of the men who state that the inquiry is not applicable to them as they are graduates of earlier years, while at least nine replies relate to men of Indian nationality.

The age-distribution is shown in more detail in Table I.

BRANCH OF MEDICINE SELECTED

Analysis of the answers to this question shows that there is a certain amount of change with age. At ages 26–28 years 44 per cent. of the males are in general practice, and this figure rises to 56 per cent. at ages 30 and over. It is obvious that men who graduate relatively late in life cannot, on the average, afford the further waiting period before earning a livelihood that the adoption of specialisation entails. The proportion engaged in specialisation therefore tends to decline with age and the proportion in general practice to rise. No other significant changes with age are apparent, and in Table II. age is ignored and more detailed information with regard to the type of work selected is given for the correspondents as a whole.

Exactly one-half are found to be occupied with general practice, and of those specifying the type of practice 43 per cent. are in partnership, 37 per cent. are working alone, and 20 per cent. are assistants.

A question was asked about the size of panel (if any) but only answered by 143 of those in general practice. The man in partnership often gave the size of the total panel and not of his own. Of 61 in practice alone 23 had a panel of over 1000, the average being 860 and the largest 2310. Of 17 in partnership the personal panel averaged 510, the highest being 1300 and only 3 above 1000.

TABLE I.—*Age*

Age last birthday.	Number of registered persons.	
	Male.	Female.
26	13	1
27	79	6
28	96	13
29	93	8
30	90	10
31–34	96	6
35–39	47	5
40 and over ..	21	4
Not stated ..	54	2
Total ..	589*	55

* Excludes six graduates of earlier years and one reported dead.

Nearly one-quarter of the total are engaged in specialties (taken in a wide sense), while another 7 per cent. hold hospital appointments and 5 per cent. are occupied in teaching and research—and individuals in both these latter groups may be aiming at eventual specialisation.

TABLE II.—*Branch of Medicine*

Branch of medicine chosen.	Males.	Females.
	Number and percentage in this branch.	Number and percentage in this branch.
General practice—		
Assistant	51 (8·8)	3
Partner	107 (18·4)	2
Alone..	92 (15·9)	3
Unspecified	41 (7·0)	1
Total	291 (50·1)	9 (18·0)
Specialties—		
Surgery	62 (10·7)	3
General medicine ..	18 (3·1)	—
Various	59 (10·2)	15
Total	139 (24·0)	18 (36·0)
Hospital appointments—		
Municipal	30 (5·2)	6 (12·0)
Unspecified	12 (2·1)	2 (4·0)
Public health	41 (7·0)	13 (26·0)
Defence services and I.M.S.	28 (4·8)	—
Teaching and research	29 (5·0)	2 (4·0)
Unclassified	10 (1·7)	—
Grand total ..	580* (100)	50 (100)

* Excludes nine of Indian nationality.

Seven per cent. have entered the public health services, and, roughly, 5 per cent. the defence services, including the I.M.S. under this title. Only two of the males report that they have given up the profession (a further one wishes to give up), one is in temporary work, and only two report that they have been unable to find permanent employment. Of the 55 females, five have given up medical work—three on marriage, one for reasons of health, and one for work in law. Of the 50 still at work about one-quarter are in the public health services, mainly occupied with child welfare and prenatal care of the mother, and over one-third in some kind of specialty—e.g., medical missionary work, obstetrics and gynæcology.

Further details of the specialties taken up by the males are given in Table III. It may be observed that nearly half those specialising have gravitated to some branch of surgery, and a little over half to some other form of specialisation.

TABLE III.—*Specialties*

Specialty selected.	Males so occupied	Specialty selected.	Males so occupied
General medicine ..	18	Surgery (general and unspecified)	37
Obstetrics and gynæcology	14	Ophthalmic surgery and ophthalmology	12
Radiology	6	Ear, nose, and throat	7
V.D. and dermatology	7	Orthopædics	5
Dental surgeon ..	4	Urological surgery ..	1
Missionary	9	Total	139
Children's diseases..	3		
Other	16		

ADDITIONAL QUALIFICATIONS

Of the 580 males 231, or 40 per cent., report that they have taken further qualifications since registration (in numerous cases more than one). As would be expected there is here a very large difference between those engaged in general practice and those in specialties. Of the 291 in general practice only 61, or approximately one-fifth, have secured a qualification subsequent to their graduation, while of the 210 engaged in specialising, in hospital appointments, and in teaching and research, 130, or nearly two-thirds, have done so. The difficulty in general practice is expressed by one who writes: "I try to study for M.R.C.P. but spare time is hopelessly inadequate."

The proportion is naturally higher among those in public health work; of the 41 so employed 32, or 78 per cent., have taken a further qualification. On the other hand, of the 28 in the defence services and I.M.S. only 7, or one-quarter, have gone beyond their registrable qualification.

Table IV. shows the further qualifications acquired by both sexes. Of the 50 women still at work exactly half had taken some further qualification.

TABLE IV.—*Additional Qualifications*

Degree or diploma.	Number with each further qualification.*	
	Males.	Females.
M.B., or equivalent.. ..	51	5
M.D.	51	6
F.R.C.S.	52	2
D.P.H.	42	13
M.R.C.P.	46	2

D.P.M.	10	—
D.T.M. & H.	17	2
Various (not more than 5 of each)	43	3

* This table gives the number of times each qualification was recorded. It does *not* show the number of persons with a further qualification, for the same person may, *and quite frequently did*, have two or more qualifications.

GROSS INCOME EARNED

Without doubt one of the most interesting aspects of this inquiry lies in the information provided as to the earning capacity of these recent graduates. This information was given freely and presumably with broad accuracy in nearly all cases. With resident posts it is sometimes doubtful whether the value of board and lodging has been included in the income given. In the few cases in which it is clear that it has not been included, £150 has been added to the income given. On many forms relating to men working abroad the incomes are expressed in foreign currencies (rupees in most cases), and these have been converted into sterling. These incomes of men abroad are analysed separately from those at home. It must be remembered that the information asked was *gross* income—i.e., *earning capacity*—and the heavy liabilities that must often have been incurred (purchase of practice, cost and upkeep of car) must not be forgotten.

Table V. shows the average income earned in different capacities. The list is easily headed by those in practice, alone or in partnership, whose average earnings were, roughly, £900 *in the year in question*. It is this group that has too the highest outgoings: 25 per cent. may reasonably be deducted for expenses, more no doubt from the higher incomes. But even so a figure of £700 should cover most of the essentials and some of the amenities of life.

Assistants in general practice averaged £400 in the year, and those engaged in some form of specialisation were at approximately the same figure. Those engaged in teaching and research posts earned the least, with an average of £360. Those in the various public services averaged approximately £450–£550.

The few women in each category earned an average income which was, except in municipal hospital appointments, appreciably below that of the men. The average income of those in posts abroad, in foreign countries or in the British Empire, was computed to be £580 for 79 men giving sufficient information and £350 for 9 women.

TABLE V.—*Individual Incomes*

Average income (gross) earned in different branches of medical work

—	Males.	Average income.*	Females.	Average income.*
General practice—				
Assistant	48	£400		
Alone	72	£910		
Partner	100	£910		
Unspecified	32	£780		
Total	252	£800	6	£400
Specialties (all, including unspecified hospital appointments) ..	112	£390	9	£290
Public health	31	£500	12	£370
Defence services (excluding I.M.S.)	17	£550	—	—
Municipal hospital appointments	26	£440	6	£380
Teaching and research ..	26	£360	—	—
Working abroad ..	79	£580	9	£350

* To nearest ten.

These figures of average incomes show very broadly the differences between the various groups but, like all averages, they suffer from the disability that they conceal the enormous variability around them. It is of no comfort to the pauper to be told that the average income of himself and a millionaire is £500,000. It is important to pass beyond these averages and to show the distribution of incomes earned. In Table VI. this distribution is shown for the various types of general practitioners (the table excludes one who through illness earned nothing). The majority (approximately two-thirds) of those acting as assistants earned between £300 and £500, but the range extends from £200 to £600. This variability is very much less than that shown by those who have set up alone. The extremes in this group are £60 and £2042! Taking broad groups gives the result that roughly one-tenth earned less than £300, about one-fifth between £300 and £600, one-quarter between £600 and £1000, and nearly half over £1000.

TABLE VI.—*General Practice*

Distribution of incomes earned in general practice (Males in British Isles)

Gross income during year.	Assistants and locums.	Alone.	Partnership.	Unspecified.
Less than £100	—	2	—	—
£100–	—	3	—	—
£200–	6	3	—	4
£300–	13	4	6	3
£400–	17	1	1	5
£500–	10	8	10	5
£600–	2	2	10	2
£700–	—	2	8	1
£800–	—	13	22	1
£1000–	—	24	33	7
£1500–	—	8	8	3
£2000 and over	—	2	1	1
Total	48	72	99*	32

* One earned nothing in the previous year, being engaged in post-graduate study.

With those in partnership the range is a little less wide, but even here it extends from £300 to £2125 (excluding one who earned nothing in the year in question, being engaged in study). Broader classification gives none below £300, about one-fifth between £300 and £600, and two-fifths in each of the groups £600–£1000 and over £1000.

Table VII. gives the income distribution for the other branches of work. The lower limit of those engaged in specialising or in teaching and research is no earned income at all, for there were 14 individuals occupied in post-graduate study (this also applies to one in the public health category who was studying during the previous year). There are a few individuals—e.g., dental surgeons, radiologists—in the over £1000 category, but the general run of incomes is much below the *gross* earnings of the general practitioners: of those included in the specialty group one-tenth earned less than £100, nearly one-third between £100 and £300, another third between £300 and £500, and only 28 per cent. earned £500 or over.

TABLE VII.—*Other Branches*

Distribution of incomes earned in different branches of medical work other than general practice (Males)

Gross income during year.	All specialties.*	Public health.	Defence services.	Municipal hospital appointments.	Teaching and research.	In work abroad.
None	10	1	—	—	4	2
Less than £100–	1	—	—	—	1	1
£100–	11	—	—	2	1	4
£200–	22	2	1	2	2	7
£300–	19	2	—	5	4	8
£400–	18	6	6	4	7	10
£500–	13	13	4	10	4	16
£600–	7	3	—	2	2	11
£700–	3	4	5	1	—	3
£800–	1	—	1	—	—	6
£1000–	5	—	—	—	1	8
£1500–	1	—	—	—	—	2
£2000 and over	1	—	—	—	—	1
Total	112	31	17	26	26	79

* Including unspecified hospital appointments.

The public health workers and those in municipal hospitals lie mainly between £300 and £600. Of the 26 persons in teaching and research 73 per cent. earned less than £500, while of those abroad 58 per cent. earned this amount or more.

TABLE VIII.—*Proportion of Males in Broad Income Groups in different occupations*

Gross income during year.	General practice.	Specialties, teaching, and research (percentages).	Public health, municipal hospitals, and defence services.	Abroad.
Less than £100	0·8	11·6	1·3	3·8
£100–	6·3	26·1	9·5	13·9
£300–	20·0	34·8	31·1	22·8
£500–	19·6	18·8	43·2	34·2
£700–	18·7	2·9	14·9	11·4
£1000 and over	34·6	5·8	—	13·9
Total	100·0	100·0	100·0	100·0

For ease of comparison the proportions falling in different broad income categories are shown in Table VIII. in four classifications of work—namely, (1) general practice, (2) specialties, teaching, and research, (3) public health, municipal hospitals, and defence services, and (4) abroad. This table shows clearly the delay in earning capacity that specialisation entails. More than one-third of the men in this category earned less than £300, compared with only 7 per cent. of those in general practice, while the *gross* earnings of nearly three-quarters of the latter reached or exceeded £500, compared with only about one-quarter of the former.

In addition to the incomes shown in these tables there were seven unclassified, two of which were nothing, three were salaries of less than £300 of men in temporary work, and three lay between £500 and £600.

The number of women involved is too small to allow any detailed analysis of their incomes. Of the 33 included in Table V., 2 earned nothing, 9 between £100 and £300, 12 between £300 and £500, and 10 over £500.

CIVIL STATE

These differences in earning capacity lead inevitably to a very large difference between the marriage rates. Taking the broad type-of-work groups of Table VIII. the proportions of men that have married are 66 per cent. in general practice, 42 per cent. in the public services (including municipal hospital appointments and the defence services), and only 35 per cent. in the group engaged in specialising, teaching, and research. Indeed the reason quite frequently given for the selection of general practice was the desire to get married, and the consequent immediate need of an adequate income. One man complains that "posts do not exist for young married men even with good hospital experience in whole-time municipal work." Other reasons for selecting a particular branch of the profession are discussed in the section below. These answers do not lend themselves to tabulation (very often the reason given is no more than "preference" or "inclination"), and therefore only a general discussion of them will be given, with attention to answers of particular interest.

REASONS FOR CHOICE

Amongst the general practitioners the most frequent answer to the question, what led you to choose this or that branch of medicine, is, as would be expected, the immediate need of an income and the lack of means to allow specialisation. As one graduate tersely expresses it, "I *had* no choice. I had to live." It is quite clear that a proportion, which, as far as information is provided, appears fairly small, regrets this force of circumstances. Some had already failed to secure other jobs, and a few openly regret the choice they made. Two or three admit interestingly that they entered general practice to gain experience for consulting work.

Other factors in general practice which appealed to an appreciable number of those who made it their choice are the possibility of following a country life, the independence of superiors, and the "human element" or "sympathetic intimacy" which this form of work offers. The general practitioner becomes, one says, "family doctor, legal adviser, and confidant." The variety of the work, especially, as several remark, in conjunction with opportunities offered at local hospitals, appeals to many, and is summed up by one who says "specialism would bore me." There is in fact some evidence that in general practice is being found a satisfaction missed in other branches.

It is interesting to observe, too, the "force of heredity." Of those in general practice 31, or roughly 1 in 9, were following in their fathers' footsteps. The "force" appears to reach its maximum in the student who reports that his desire was to be an engineer but that his grandfather, father, three uncles, two aunts, and one brother were already doctors! Medicine, another said, is a family failing. This factor is also apparent amongst those following some specialty, of whom 12, or about 1 in 12, regard it as influencing their choice.

In general the reasons given by this group are somewhat indeterminate, the majority either stressing the specific interest of the work they have selected or asserting its superiority by invidious comparisons with general practice. In the latter they think there is monotony, a lack of regular hours or free time for other interests, the objection of night work, the lack of time to give to each patient, and finally the "burden of the panel system" and the "commercialisation of general practice." A proportion of those specialising have been led to it by their particular interests being aroused in their undergraduate days, by the encouragement of their tutors, and by an ambition to gain further experience and knowledge. "To do one job well rather than be mediocre in all," one expresses it. Ill-health has made general practice inadvisable in a few cases. "Mechanical aptitude" is advanced as a reason for selecting surgery as a career.

The workers in public health naturally lay stress on the advantages of a steady income, settled hours, and eventual pension. As one says, "It is a safe job; the monthly cheque arrives, there are no bills to send out, no bad debts, and no initial outlay of capital." There is also amongst them a fairly widespread belief in the future and expansion of the field of preventive medicine and of the municipal hospital system.

SUMMARY AND CONCLUSIONS

In this article an analysis is made of the replies to a questionnaire returned by 651 medical men and women resident, mainly, in Great Britain: 596 of these persons were men and 55 were women, a sex ratio of 11 to 1. Two-thirds belonged to the age-group 27–30 years. Just one-half of the males had entered general practice, a little over one-quarter were engaged in some form of specialisation (including teaching and research), and approximately 12 per cent. were in the public health services in this country or abroad (including in this category the defence services). Further qualifications have been obtained by 40 per cent. of the males, the distribution being 21 per cent. amongst general practitioners, 62 per cent. amongst those specialising, and 78 per cent. amongst those in the public health service (excluding those in the defence services).

Of the general practitioners nearly three-quarters had a *gross* income last year reaching or exceeding £500. Of those specialising only just over one-quarter exceeded this figure, of those in the public health service nearly 60 per cent. Two-thirds of the general practitioners had been able to marry as opposed to 35 per cent. of those specialising and 42 per cent. of those engaged in public health work.

Taking the replies as a whole it is clear that these recent graduates have settled in their profession with a substantial degree of success. Naturally enough there is a number who have definitely been unsuccessful, who think, as one says, that the prospects are "bleak and depressing," and that the opportunities in the future of obtaining satisfactory remunerative work are slender. But it does not appear to be a large number. Whether these persons are in such a minority through a tendency for the successful to reply to the questionnaire rather than the unsuccessful we cannot determine. It is possible that the sample here analysed may present too favourable a picture of the profession. While hoping that it does not, we must bear the proviso in mind in drawing any conclusions from the results.

THE MEDICAL SERVICES

NAVAL MEDICAL SERVICE

THE Naval Medical Service now offers to well-qualified medical men a very satisfactory career, with excellent opportunities for the practice of their profession and for specialisation in many subjects; the pay is good, and so is the prospect of promotion to the higher ranks with an adequate pension on retirement.

The following information embodies the principal conditions of service.

Entries will be on a Short Service basis, and will be for an initial period of 3 years, to be extended to 5 years at the discretion of the Admiralty.

Officers leaving the service at the end of 3 years will be eligible for a gratuity of £400, whilst those who leave at the end of 5 years will receive £1000.

Officers may be transferred to the Permanent List at the discretion of the Admiralty on completion of 5 years' Short Service. A gratuity of £1000 will be paid, but the Officer will be required to render a minimum of 25 years' service in order to qualify for full pension, including seniority granted, if any, in respect of Civil Hospital time. With regard to the latter, antedate of seniority of not more than one year may be allowed in respect of resident appointments in Civil Hospitals held prior to entry to the R.N. Medical Service. The antedate will count for seniority and eligibility for increase of pay, and if the officer is transferred to the permanent list it will count also as service for the purposes of promotion and retired pay, or gratuity on retirement.

Opportunities will be afforded for officers to specialise during the course of their career, and the number of Specialists posts carrying additional emoluments is 83.

The age of retirement in the case of Surgeon Commanders is 55, and in the case of Surgeon Captains 57.

Candidates *must not* be above the age of 28 years.

KITCHENER MEDICAL SCHOLARSHIPS

By arrangement with the Lord Kitchener National Memorial Fund these Scholarships may be awarded to the sons of Officers and Men or of ex-Officers and Men of H.M. Forces who desire to take a medical training with a view to obtaining a regular Commission in the Medical Services of the Navy, Army, or Air Force. Since the cost of Scholarships awarded to Candidates who enter the Royal Navy is borne by Naval Funds, a sum not exceeding the total value of the Scholarship will be deducted, at the discretion of the Admiralty, from any gratuity which may be payable to a Scholarship holder who fails to serve for 15 years in the Royal Navy.

MEDALS AND PRIZES

Gilbert Blane Medal.—This Medal is awarded annually to the Surgeon Lieutenant-Commander who obtains the highest aggregate marks at the examination for promotion to the rank of Surgeon Commander. The award is subject to the approval of the Presidents of the Royal College of Physicians and Surgeons respectively and the Medical Director-General of the Navy.

Other awards and prizes open to Naval Medical Officers are the Chadwick Naval Prize, the North Persian Forces Memorial Medal, and the Parkes Memorial Prize.

PAY AND ALLOWANCES

The old regulation by which officers were admitted direct to the Permanent Service by examination is now abolished. No examination for entry is held, but candidates will be required to present themselves before a Selection Board at the Admiralty presided over by the Medical Director-General of the Navy, to whom application should be made for further details.

Full Pay (as from July 1st, 1935)

		£		£	
SURGEON LIEUTENANT (short service and permanent service)	from	438	to	478	per annum.
SURGEON LIEUTENANT-COMMANDER (promoted after six years' service)	„	578	„	611	„
SURGEON COMMANDER (promoted after a further six years' service)	„	742	„	1058½	„
SURGEON CAPTAIN (promoted by selection)	„	1074	„	1320	„
SURGEON REAR-ADMIRAL (promoted by selection)		1734			„
MEDICAL DIRECTOR-GENERAL ..		2262½			„

Allowances

An outfit allowance of £50 towards cost of uniform is given.

Allowances when in charge of hospitals and sick quarters ..	10*s.* and 5*s.* per diem.
Eighty-three Specialist allowances of	5*s.* per diem.
Allowances to Senior Medical Officers in flagships	5*s.* and 2*s.* 6*d.* per diem.

Accelerated promotion can be gained under certain conditions: provision allowance and lodging allowance are paid when victualling and accommodation are *not* provided. Servant's allowance is also payable in certain appointments.

The extra allowances alluded to in this Table are *not to be looked upon as very exceptional.* About a quarter of the Medical Officers of the Navy are drawing extra allowances.

PENSION

Naval Officers retire at certain ages according to the rank they have attained. Except for those promoted to the 40 higher posts, the usual retiring age is 55 as Surgeon Commander, the appropriate pension according to scale being £543 per annum.

The current scale of pensions is as follows:—

	Maximum retired pay.			
SURGEON VICE-ADMIRAL ..	£1082	per annum on vacating office.		
SURGEON REAR-ADMIRAL ..	£914½	per annum at age of		60.
SURGEON CAPTAIN	£814½	„	„	57.
SURGEON COMMANDER	£543	„	„	55.
SURGEON LIEUTENANT-COMMANDER AND SURGEON LIEUTENANT	£407½	„	„	45.

Officers permitted to withdraw receive gratuities on the following scale:—

	£
Over 10 and under 15 years' service ..	500
„ 15 „ „ 18 „ „ ..	1800
„ 18 years' service	2700

Dental Branch

Candidates, who must be qualified dental surgeons and below the age of 28 years, are required to produce *certificates of birth*, registration, and of character, and must be physically fit for active service anywhere. An outfit allowance of £50 is payable to officers finally entered and commissioned. The rank of Surgeon Lieutenant-Commander (D) is attained on the completion of six years' satisfactory service. Promotions to Surgeon Commander (D) and Surgeon Captain (D) are made *strictly by selection* from the rank next below and are confined to officers who prove fitted in every respect for these ranks. The present establishment of dental officers is: 1 Surgeon Captain (D), 3 Surgeon

Commanders (D), 60 Surgeon Lieutenant-Commanders (D) and Surgeon Lieutenants (D).

Provision has been made for candidates who have held, or who, at the time of passing the examination hold or are about to hold, an appointment as Dental Officer in a recognised Civil Hospital to be allowed to serve in such appointment after the date of entry into the R.N. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list.

On the completion of two years' service in the rank of Surgeon Lieutenant-Commander (D), dental officers on the Active List are eligible for a three months' post-graduate course at a dental hospital and school at the public expense, and will draw full pay while attending the course.

Pay.—The rates of full pay for Dental Officers (as from July 1st, 1935) are as follows:—

	£ £
Surgeon Lieutenant (D)	362–447
Surgeon Lieutenant-Commander (D) (promoted after six years' service)	535–660
Surgeon Commander (D) (promoted by selection to fill vacancies in Establishment)	703–900
Surgeon Captain (D) (promoted by selection to fill vacancy in Establishment)	1031–1281

The Regulations regarding Pension and Withdrawal Gratuities are the same as for Medical Officers in the corresponding Ranks.

ARMY MEDICAL SERVICE

Royal Army Medical Corps

THE appointment of officers to the Royal Army Medical Corps will, in the first instance, be by means of a Short Service Commission for a period of five years. In the fifth year of service an officer will be given the choice of retiring with a gratuity of £1000 or of applying for a permanent commission. Those retiring with a gratuity after five years' service will be liable to be called up for duty in the event of a national emergency arising during the twelve years following their retirement.

New entrants are commissioned in the rank of Lieutenant, and the first three months of their service are on probation, during which time they undergo a course at the Royal Army Medical College in London, in Hygiene, Tropical Medicine, Entomology, &c., &c., in addition to their military training at the Royal Army Medical Corps Depôt at Aldershot. A grant of £50 is made for the purchase of uniform.

An entrant who is holding or who is about to hold at the time of entrance an approved whole-time appointment at a recognised Civil Hospital may be seconded while holding such appointment up to a maximum period of 12 months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to 12 months in respect of the period the appointment was held. The period of secondment or antedate will not reckon in diminution of the period of five years which he is required to serve on a short service commission, but on completing one year of actual service in the R.A.M.C. the period of secondment or antedate will count for seniority.

If appointed to a permanent commission the period of secondment or antedate will count as service for promotion to the rank of Major, increases of pay in the ranks of Captain and Major, and retirement on retired pay or with gratuity.

PROMOTION

Promotion to Captain will be after one year's commissioned service on full pay. If appointed to a permanent commission promotion to the rank of Major will be on completion of 10 years' commissioned service. Promotion to the ranks of Lieutenant-Colonel and Colonel will be by selection to fill vacancies within the establishment which is designed to allow promotion to those ranks on the average after 17 and 25 years' service respectively.

PROFESSIONAL OPPORTUNITY

The possibilities for good work are very great. There is scope for original research in tropical diseases, in preventive medicine, and in bacteriology, as well as in the large clinical field open to the specialist in Medicine, Surgery, Gynæcology, Diseases of the Ear, Nose, and Throat, Ophthalmology, and Venereal Diseases. Child Welfare is also undertaken systematically by officers of the R.A.M.C.

FOREIGN SERVICE

The tour of foreign service in India or the Mediterranean Stations is five years, that of the Colonies three years, but in the case of those officers retiring on a gratuity after five years' service, arrangements would be made for them to return to England at public expense by the end of that period.

POST-GRADUATE STUDY

A permanent commissioned officer will, between his sixth and tenth year of service, undergo a course of post-graduate study at the Royal Army Medical College and the London hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the post-graduate course or during his previous service. During this course of study he remains on full pay, and the fees for the course are paid by the State.

When qualified in his special subject, the officer up to and including the rank of Lieutenant-Colonel becomes entitled to specialist pay at 4*s.* 6*d.* per day when holding a specialist appointment.

PAY AND ALLOWANCES (HOME RATES)

The rates of pay and allowances for officers are at present as shown in the Table, but the allowance rates vary slightly from time to time. In addition, specialist pay and charge pay are given under certain conditions as noted below.

ADDITIONAL PAY

An officer below the substantive rank of Colonel holding an appointment as specialist receives 4*s.* 6*d.* a day, in addition to his ordinary pay.

The Adjutant, R.A.M.C. Depôt, receives 5*s.* a day in addition to his ordinary pay.

CHARGE PAY	Daily. *s.*	*d.*
(*a*) An officer below the substantive rank of Colonel in charge of a hospital of 50 beds and over, or in charge of a medical or surgical division of a general hospital with at least 300 beds	5	0
(*b*) Senior Medical Officer, Royal Arsenal ..	5	0

Assistant Professors at the Royal Army Medical College (Lieutenant-Colonels) receive pay and allowances of their rank plus £90 10*s.* a year.

GRATUITIES; SHORT SERVICE OFFICERS

The gratuity of £1000 granted on retirement, after five years' service as a medical officer to a short service officer who does not obtain a permanent commission is generous, and should go a long way to enable an officer on leaving the Service towards establishing himself in Civil life.

Entry takes place twice yearly at the beginning of May and November.

Regulations for admission, giving full details and application forms, should be obtained from the Assistant Director-General, Army Medical Services (A.M.D.1), The War Office, Whitehall, London, S.W.1.

Lieutenant-Colonel	2 12 0	1 3	2 0	4 6	3 0	2 0	4 6	2 4	1183	1134
After 3 years' service as such	2 16 6	1 3	2 0	4 6	3 0	2 0	4 6	2 4	1265	1217
Colonel	3 3 4	1 3	2 0	5 6	3 11	2 0	5 6	2 8	1425	1366
Major-General	4 6 0	1 3	4 0	11 0	4 10	2 0	11 0	3 10	1992	1937
Director-General	5 8 8	1 3	6 0	13 9	5 5	2 0	13 9	4 5	2502	2447

* The rates of pay shown in the above Table are the rates issuable with effect from July 1st, 1935.

† These rates apply when rations cannot be issued in kind.

‡ A married officer for the purposes of furniture, lodging, fuel, and light allowances is one who is married and is 30 years of age or over.

RETIREMENT AND RETIRED PAY: OFFICERS HOLDING PERMANENT COMMISSIONS

The following are the rates of retired pay:—

1. Retired pay consists of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible to retire voluntarily on service retired pay.

2. The scale will be as follows:—

(*a*) Service element.—£13 11*s*. 6*d*. a year for each completed year of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£ s. d.	£ s. d.	£ s. d.
Major	10 17 3	10 17 3	108 12 6
Lieutenant-Colonel	135 15 0	27 3 0	217 4 0
Colonel	262 9 0	45 5 0	352 19 0
Major-General ..	398 4 0	45 5 0	488 14 0
Lieutenant-General	533 19 0	45 5 0	624 9 0

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together:—

	£ s. d.		£ s. d.
Major	407 5 0	Major-General ..	905 0 0
Lieutenant-Colonel	543 0 0	Lieutenant-General	1086 0 0
Colonel	724 0 0		

3. Officers may be permitted to retire with a gratuity in accordance with the following scale:—

With less than 10 years' service as a medical officer	£1000
After 10 years' service as a medical officer ..	£1500
„ 15 „ „ „ „ ..	£2800
„ 18 „ „ „ „ ..	£3500

The Army Dental Corps

This Corps is administered by the Director-General, Army Medical Services. Regulations for admission to The Army Dental Corps should be obtained from the Under Secretary of State, War Office, and carefully studied.

OFFICERS: APPOINTMENT AND PROMOTION

1. Commissions as Lieutenants in The Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2. An officer who is commissioned after holding an approved whole-time appointment in a recognised civil dental hospital or in the dental department of a recognised civil general hospital may be granted an antedate covering the period of his appointment, but not exceeding six months, provided that the interval between the termination of the hospital appointment and the date of entry into the Service does not ordinarily exceed six months. The period of such antedate will reckon towards promotion, increase of pay, gratuity, or retired pay.

3. An officer is eligible for promotion to the rank of Captain on completion of three and a half years' service and to the rank of Major on completion of 12 years' service in the Corps, provided he has previously qualified in such manner as may be prescribed by the Army Council.

4. Promotion to the rank of Lieutenant-Colonel and Colonel to fill the establishments laid down from time to time for those ranks is made by selection from those senior in the rank below. Dental officers are also eligible for special promotion by brevet.

PAY

The following are the rates of pay for officers of The Army Dental Corps.

	Per diem. £ s. d.
Lieutenant	18 2
Captain	1 2 8
Captain { after 8 years' total service ..	1 5 4
Captain { „ 10 „ „ „ ..	1 7 2
Major	1 11 8
Major, after 15 years' total service	1 16 2
„ „ 18 „ „ „	1 18 6
„ „ 20 „ „ „	2 3 0
Lieutenant-Colonel	2 9 10
Lieutenant-Colonel after 3 years' service as such	2 14 4
Colonel	3 1 2

CHARGE PAY

The officer in charge of the Dental Laboratories, Aldershot, receives charge pay at the rate of 5*s.* a day if holding the rank of Captain, or 2*s.* 6*d.* a day if holding the rank of Major.

ALLOWANCES

The allowances for officers of The Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

RETIREMENT AND RETIRED PAY OR GRATUITY

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after 20 years' service.

(3) Earlier retirement on gratuity may be allowed:—

After 8½ years'	service as a Dental Officer,	gratuity of £1000.
" 15 "		" £2000.
" 18 "		" £3000.

The aim of the Corps is the prevention of wastage on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier is reinspected at least once a year and the dental efficiency maintained at the best standard possible.

INDIAN MEDICAL SERVICE

COMPETITIVE examination remains suspended for the present and admission to the Service is on written application to the India Office. As sound bodily health is a first essential candidates may, if they wish it, undergo a preliminary examination by a Medical Board which meets weekly at the India Office.

Candidates must be under 32 years of age at the time of appointment, and must possess a qualification registered under the Medical Acts in force at the time of appointment. The Indian Medical Service is designed primarily to meet the needs of the Indian Army, but in order to maintain the necessary minimum war reserve of military medical officers, and to provide for European medical attendance for European officers of the Superior Civil Services and their families, local governments are required to employ a stated number of Indian Medical Service officers. The Government of India draw on the same Service to meet the requirements of the civil administration for which they are responsible. It is a definite condition of service that officers will be liable to serve on either the civil or the military side. All officers are required to perform at least one year's military duty subsequent to permanent appointment before they can be considered eligible for civil employment. Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it. On the military side, however, the opportunities for private practice are not great. The commissions of officers who before appointment have obtained certain higher qualifications or have held resident appointments in certain hospitals may be antedated by one year.

PROSPECTS

Although there are still two schools of thought with regard to the future prospects of the Indian Medical Service, the optimists have become more optimistic during the past year and the pessimists less pessimistic. Shrewd judges of the situation are now of opinion that the prospects of really good candidates are as bright as ever they were: perhaps not for those whose one object is to amass a fortune, but for men who are attracted by a service which offers a great variety of choice of interesting lines of work such as medical, surgical, public health, and research. The pay and pensions are attractive, though junior married officers must expect to live quietly if they are not to exceed their incomes. The cautionary notice in official announcements with regard to prospects of civil employ has been withdrawn, as it has now been decided in principle that a number of civil appointments must continue to be reserved for European I.M.S. officers, including attractive specialist posts and civil surgeoncies. The number of these has not yet been settled, and will no doubt be smaller than in the past; but highly qualified men have a reasonable assurance of securing congenial civil appointments after a period of military service of varying duration. Those who enter the Service at an early age have a definite advantage over those who delay till several years after qualification. The ideal course is to enter after spending a year in a resident hospital appointment; this year will be antedated, and the candidate can enter the Service with the rank and pay of a captain. An important point to note is that permanent commissions are granted at once so that an officer can look forward with confidence to a settled career, and is not subject to the risks of a short-service system. He reaps however the advantages of such a system, for he can retire voluntarily after six years with a gratuity of £1000, after twelve years' service with a gratuity of £2500, and many young doctors have joined with this intention; very few officers have actually taken advantage of the offer. Conditions of service have been constantly changing and are likely to go on changing in the future, but they have never been such as to prevent men of ability and enterprise from carving out distinguished careers for themselves.

RATES OF PAY

The monthly rates of pay for European officers of non-Asiatic domicile in the Service are as tabulated below. The rupee, it may be remembered, is worth 1*s.* 6*d.*

Rank and service in rank.	Basic pay.	Overseas pay.	Year of total service.
	Rs.	Rs.	
Lieut.	500	150	First
Captain :—			
1. During first three years' service as Captain.	650	150	Second
		150	Third
		150	Fourth
2. With more than three and less than six years' service as Captain.	750	£15	Fifth
		£15	Sixth
		£25	Seventh
3. With more than six years' service as Captain.	850	£25	Eighth
		£25	Ninth
		£25	Tenth
		£25	Eleventh
		£30	Twelfth
Major :—			
1. During first three years' service as Major	950	£30	Thirteenth and over
2. With more than three and less than six years' service as Major	1100		
3. With more than six years' service as Major	1250		
Lieut.-Colonel :—			
1. Until completion of 23 years' total service	1500		
2. During twenty-fourth and twenty-fifth years' total service	1600		
3. After completion of 25 years' total service	1700		
4. When selected for increased pay ..	1850		

NOTE TO TABLE

Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time-scale of promotion. Overseas pay is regulated solely with reference to length of total service (column 4). In addition to the above rates various allowances

(*Continued at foot of opposite page*)

Officers on arrival in India will be posted for one year to specially selected stations. Officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowances. On the civil side there are public health, bacteriological, research, and professorial appointments carrying special enhanced rates. Officers on appointment receive an outfit allowance of £50.

PENSIONS AND ALLOWANCES

The rates of pensions, as from July 1st, 1935, are as shown in the Table below.

Service.	Rates per annum.	Service.	Rates per annum.
After 17 years ..	£372	After 23 years ..	£576/10/-
„ 18 „ ..	400	„ 24 „ ..	614
„ 19 „ ..	428	„ 25 „ ..	651
„ 20 „ ..	465	„ 26 „ ..	697/10/-
„ 21 „ ..	502	„ 27 „ ..	744
„ 22 „ ..	539/10/-		

There are additional pensions ranging from £65 to £350 per annum for officers who have held high *administrative appointments* as colonels or major-generals.

Officers on appointment are provided with free passage to India, normally by transport. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India subject to the payment of messing charges. Officers are granted a certain number of return passages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S.W.1. Letters should be marked "Recruitment for I.M.S."

MEDICAL BRANCH OF THE ROYAL AIR FORCE

THE Air Council attach great importance to attracting into the service the best type of medical man, since on the capacity of the Medical Branch depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection, and as a certain proportion of the higher ranks are reserved for purely professional as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in his professional work.

The work to be done, therefore, has a high professional interest, combined with good rates of pay and allowances, so that a career is offered which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation.

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve. He may also, if he wishes, undergo a certain amount of training as a pilot, when this can be arranged without interference with his duties.

The establishment consists partly of permanent and partly of short-service officers, and an officer on entry is granted a short-service commission for a period of three years on the active list (extensible to five years if the officer so wishes, on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions are made from officers holding short-service commissions who are considered to be suitable and who desire a life career in the service. Those who are not selected are transferred to the Reserve at the expiration of their period of service on the active list.

But the short-service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subsequently entering private practice, and who, on entry, have not made up their minds to the adoption of a permanent career in the Service.

For certain purposes medical officers may be allowed to count as service their time spent in approved whole-time post-graduate appointments in civil hospitals under certain well-defined and generous conditions.

At about five years' service all permanent officers who are judged suitable will be given the opportunity to take a course of specialist study. The period allowed will vary with the subject of study, but normally about nine months will be available to each officer, during which full pay and allowances will be issued. Their subsequent career will normally be as follows. Approximately three-quarters of the employment of squadron leaders and senior flight lieutenants is in specialist posts, though these are not generally of a full-time specialist character. On reaching the rank of wing commander, the policy is to allow a proportion of officers to become permanent specialists and to be employed continuously throughout the remainder of their career in full-time specialist posts. Rather more than a quarter of the officers will become permanent specialists and continue to be employed as such throughout their service in the ranks of wing commander and group captain. In addition there are a number of hygiene posts in the former rank open to specialists in that subject, bringing the proportion of specialist posts in the rank up to nearly a half of the total posts. In the rank of group captain, apart from the posts already mentioned as available for the permanent specialist, employment is nearly equally divided between posts in charge of a large hospital and headquarter administrative posts. This statement indicates the position as regards specialist employment as at present foreseen. No guarantee can be given, of course, that the career of an individual will necessarily conform to this forecast.

New entrants into the Royal Air Force Medical Branch are commissioned as Flying Officers (Medical), and are eligible for promotion to the rank of Flight Lieutenant (Medical) after one year's service on full pay. Permanent officers are normally promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted after the completion of eight years' service to officers qualified to hold specialist appointments. Promotion within establishment to the ranks of Wing Commander and above is by selection. The number of permanent commissions granted yearly is regulated with iew to all suitable permanent officers being p

---

(Continued from previous page)

are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the I.M.S. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service. The appointment of Director-General, I.M.S., which is held by an I.M.S. officer, carries pay of Rs.3500 per mensem. The appointment of Director of Medical Services in India, carrying pay at Rs.3200 per mensem, may also be held by an officer of the Indian Medical Service.

* Except for periods of service under Indian administration. For such periods, officers receive pay and allowances at rates and subject to conditions authorised *from time to time by the Government of India.*

† *These allowances are issued only when accommodation, fuel and light, rations, and personal attendance are not available in kind. Normally, provision in kind is available for junior officers. "Married" rates of allowances are payable only to married officers who have reached the age of 30 or the rank of Squadron Leader. The rates and general scheme of allowances are liable to revision as circumstances may require.*

Wing Commanders and of a substantial majority of Wing Commanders being promoted to Group Captains. While the aim is to give entrants a career as above, no guarantee of promotion can be given to the individual officer, of course, since the number of vacancies for promotion must depend on the requirements of the Service from time to time.

There is no competitive examination on entry; candidates must be under 28 years of age, British subjects, the sons of British subjects, and of pure European descent, and are interviewed by a Board presided over by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce:—

1. Birth certificate. 2. Medical registration certificate. 3. A declaration containing the following information: (*a*) Age and place of birth. (*b*) That he is a British subject, the son of British subjects, and of pure European descent. (*c*) That he is ready to engage for general service at home or abroad as required. (*d*) The qualifications he is possessed of, and what medical or other appointments he has held (if any). (*e*) That he is willing to fly as a passenger whenever called upon to do so.

Each candidate is required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants undergo an initial course of three months, during which they are given instruction in the special medical aspects of aviation, the organisation and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch.

In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List is determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

UNIFORM AND EQUIPMENT

Medical officers are required to provide themselves with the uniform, service dress, and mess dress of their rank, and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

EMOLUMENTS

The emoluments of medical officers of the Royal Air Force are given in outline below. The rates of pay are fixed on an inclusive basis, and the fact that specialist pay and charge pay are not payable as separate emoluments was taken into account when the rates were fixed.

ALLOWANCES AT STATIONS ABROAD

In addition to the pay shown above, officers stationed abroad are provided with furnished quarters (with fuel and light) and rations, or allowances in lieu, and receive colonial and servant allowances. The present annual total of the allowances (including colonial and servant allowances) payable when provision in kind is not available is as follows:—

Rank.	Egypt		Palestine		Malta		Malaya	
	M.	S.	M.	S.	M.	S.	M.	S.
	p.a. £	p.a. £	p.a. £	p.a. £	p.a. £	p.a. £	p.a. £	p.a. £
Flying Officer ..	432	221	440	231	278	135	621	272
Flight Lieutenant ..	432	221	456	231	278	135	621	272
Squadron Leader ..	432	272	458	284	278	151	621	298
Wing Commander ..	534	327	551	345	321	165	694	399
Group Captain ..	570	363	601	386	357	202	720	425

M. =married. S. =single.

The married rates are payable only when the officer is accompanied by his family. If unaccompanied he is treated as unmarried for the purposes of his own accommodation, or allowances in lieu, and receives a consolidated allowance in respect of the separated family as follows:—

Flying Officer	£109 p.a.
Flight Lieut. and Squadron Leader..	£136 ,,
Wing Cmdr. and Group Captain ..	£173 ,,

Iraq and Sudan.—Families are normally not allowed in these countries, and officers are provided with accommodation, &c., for themselves, and receive colonial and servant allowances. The present rates of colonial allowance amount to £142 p.a. (Iraq) and £55 p.a. (Sudan). In addition, married officers receive the consolidated allowance for separated families at the rates shown above.

Aden and Transjordan.—Families are normally only allowed at these stations if public married quarters are available. Married officers accompanied by their families are accordingly provided with married accommodation, &c., and receive a servant allowance of 2*s.* a day and a colonial allowance of 10*s.* a day at Aden and 7*s.* a day in Transjordan. Other officers are provided with unmarried accommodation and receive servant allowance of 2*s.* a day and colonial allowance of 5*s.* a day at Aden and 3*s.* 3*d.* a day in Transjordan. In addition, married officers separated from their families receive the consolidated allowance at the rates shown above.

The rates of colonial allowance in all commands are at present under review.

Retired Pay

The minimum period of service qualifying for retirement on retired pay is 20 years.

The scales of retired pay are as follows :—

AIR OFFICERS

Air Vice-Marshal ..	£714 10s. to £914 10s.	per annum.	
Air Commodore ..	£588 ,, £860	,,	,,

OFFICERS BELOW AIR RANK

Age on retirement.	Yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£ s.		£ s.	£ s.
40	271 10	17	13 10	13 10
41	305 0	17	13 10	13 10
42	339 10	18	13 10	13 10
43	373 0	18	13 10	13 10
44	407 10	19	13 10	13 10

53	671 10	23	20 0	13 10
54	692 0	24	20 0	13 10
55	714 10	24	20 0	13 10

* Limited to five years.

The maximum rates of retired pay and the compulsory retiring ages for the several ranks are :—

Rank.	Yearly rate of retired pay.	Compulsory retiring age.
	£ s.	
Air Vice-Marshal ..	914 10	60
Air Commodore ..	860 0	57
Group Captain ..	814 10	57
Wing Commander ..	543 0	55
Squadron Leader ..	452 10	55

Gratuities.—A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity, namely :—

£1000 if he has 5 but less than 10 years' commissioned service.
£1500 ,, ,, 10 ,, ,, 15 ,, ,, ,,
£2800 ,, ,, 15 or more than 15 ,, ,, ,,

Short-service officers who complete their full period of service on the active list will normally be granted gratuity as follows on transfer to the Reserve :—

After 3 completed years	£400
,, 5 ,, ,, ...	£1000

These gratuities will not be payable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay.

COLONIAL MEDICAL SERVICE

THE Colonial Medical Service consists of the Medical Services in Bahamas, Barbados, Bermuda, British Guiana, British Honduras, British Solomon Islands Protectorate, Ceylon, Cyprus, Falkland Islands, Fiji, Gambia, Gibraltar, Gilbert and Ellice Islands Colony, Gold Coast, Hong-Kong, Jamaica, Kenya, Leeward Islands, Malaya, Mauritius, Nigeria, Northern Rhodesia, Nyasaland, Palestine, St. Helena, Seychelles, Sierra Leone, Somaliland, Tanganyika, Trinidad, Uganda, Windward Islands, and Zanzibar.

The various Colonial government medical departments employ some 1200 European medical officers and about the same number of qualified Asiatic and African medical officers who are appointed locally. Included in this total are about 30 qualified European women medical officers. About 850 trained nursing sisters and health visitors are employed, most of whom are Europeans. There are large numbers of subordinate personnel, sanitary inspectors, medical assistants, and dressers, most of whom are natives of the areas in which they serve.

Throughout nearly the whole of the Colonial Empire such diseases as malaria, yaws, leprosy, and hookworm disease menace the health of the indigenous people and retard development. In equatorial Africa sleeping sickness and plague persist, in West Africa yellow fever has not yet been eradicated, and in the Near and Far East outbreaks of cholera and plague occur from time to time. In addition to tropical diseases, those maladies usually met with in this country are prevalent throughout the Empire.

An officer in the Colonial Medical Service thus has unique opportunities for the practice of his profession. On joining a medical department his duties include medical, surgical, and public health work. He may be posted to an outlying or bush station where he will be responsible for all the medical activities in connexion therewith; or he may be attached for duty at one of the large hospitals. Every encouragement will be given him to pursue any specialist work in which he may be interested so far as the exigencies of the Service permit. Great importance is attached to a candidate's post-graduate experience, as in the outlying districts he will frequently be called on to deal with emergencies without being able to seek the advice and assistance of his colleagues.

VACANCIES

Vacancies for medical officers may occur at any time of the year, and are dealt with as circumstances require. The almost complete cessation of recruitment during the war period, coupled with the post-war expansion of staffs, particularly in the larger Colonies, resulted in an abnormally high rate of recruitment. The average for the six years, 1924 to 1929, was 104 vacancies per annum. In 1930 the number of vacancies fell to 77, due to the establishments of medical departments being almost at full strength. As a result of the general financial depression only 35 vacancies were filled in 1931, and the number was further reduced to 12, 22, and 31 in 1932, 1933, and 1934 respectively. For the present vacancies are likely to be limited in number. In normal circumstances vacancies occur most frequently and regularly in Tropical Africa and Malaya. In the Bahamas, Barbados, Bermuda, Ceylon, Jamaica, and Mauritius, junior posts are practically always filled by the appointment of qualified local candidates. The vacancies for which candidates are selected from outside the Service are those for ordinary medical officers. Appointments for specialists are almost invariably reserved for officers who are already in the Service, and who have shown outstanding merit in a particular branch of medicine or surgery. Under normal conditions about six vacancies were to be expected annually, usually in West Africa and in Malaya, for women medical officers.

QUALIFICATIONS

Applicants must be under 35 years of age, and preference is given to candidates under 30. For certain appointments candidates must be of European parentage.

Preference will be given to applicants who have held hospital or public health appointments or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose, and throat, or venereal diseases. In the case of women medical officers experience in maternity and child welfare is almost essential.

Selected candidates will normally be required to undergo a course of instruction at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine or at Edinburgh University before taking up their appointments. The cost of tuition will be paid by the Government, but candidates must make their own arrangements for board and lodging. An allowance of £25 a month will be paid to them monthly in arrear while they are under instruction. Candidates who are successful in obtaining the diploma in tropical medicine and hygiene of London, Liverpool, or Edinburgh are granted a refund of their examination fees. If an officer has not taken a course of instruction in tropical medicine prior to appointment, he is usually required to take one during his first leave of absence and to obtain a satisfactory certificate before he can be confirmed in his appointment.

GENERAL CONDITIONS OF SERVICE

New entrants to the Service will be liable to transfer to any scheduled post therein, whether or not such transfer represents promotion, provided that:

(*a*) No officer whose first appointment is to an office in a Dependency in which he was ordinarily resident at the time of appointment shall be liable to be transferred to an office outside that Dependency unless and until he shall have accepted an office in another Dependency.

(*b*) No officer shall be transferred without his own consent to an office which in the opinion of the Secretary of State is of less value (due regard being had to climate and other circumstances) than that which he already holds.

Officers who do not hold scheduled posts are eligible to apply for transfer to such posts. Appointment confirmation, promotion, retirement, and transfer of Medical Officers will be governed by the directions of the Secretary of State.

No officer of the Service is entitled, as of right, to private practice, the Service being envisaged as essentially a Service of whole-time officials whose primary duty is to the State.

In view of the present financial stringency it has been found necessary in certain Colonial Administrations to impose a temporary levy on salaries. The actual value of an appointment is often much greater than is indicated by the salary alone. An applicant should take into consideration whether the post is pensionable; whether free quarters are provided; whether any special local allowances are payable; whether free passages are provided on first appointment and when proceeding on leave; and whether free or assisted passages are provided for the wives and children of married officers. If local income-tax exists in a colony it is much lower than that payable at home.

The majority of appointments are pensionable. Officers appointed to pensionable posts serve on probation in the first instance, the probationary period varying in different services—e.g., two years in East Africa, three years in West Africa. Some appointments are temporary, and service in these does not qualify for pension unless the appointment is subsequently made pensionable.

Information as to the conditions and cost of in the colonies, protectorates, and mandated ter is contained in a publication of that title (C No. 56), which may be obtained from H.M. Stat Office, price 3*s*. Further information as staffs, the climate, and local conditions will be in the Dominions Office and Colonial Offic Leaflets concerning nearly all the tropical dencies are issued for the use of intending settle others by the Oversea Settlement Depar Dominions Office, Caxton House, Tothill- London, S.W.1. A memorandum on Appointments issued by the Colonial Office sent without charge on application to the Dire Recruitment.

Applications for medical appointments i Colonial Service should be addressed to the Di of Recruitment (Colonial Service), Colonial 2, Richmond-terrace, Whitehall, London, For the present no candidate will be consider the Secretary of State for the Colonies who di —if of suitable age—serve in some branch Majesty's Forces during the Great War, unle reasons for not having done so are considered er satisfactory by the Secretary of State.

PARTICULAR CONDITIONS OF SERVICE

Tropical Africa

EAST AFRICA

Selected candidates are appointed as m officers on probation in the first instance fo years, at the end of which period their appoint are made permanent if their service has been factory, and a native language test has been p Later on a special course of study must be while on leave. Candidates can generally take wives with them on first appointment.

Officers are provided with quarters free of r the Government may provide temporary accom tion, or an allowance in lieu of quarters may be The salary of a medical or health officer is per annum, rising by annual increments of £ £840, and thence by increments of £40 to subject to an efficiency bar at £840. Senior me officers and senior health officers are pai the scale £1000 by annual increments of £5 £1100.

Officers appointed to any East African Depend excepting Northern Rhodesia are permitted to with gratuity, if they wish, instead of waiting to on pension, as follows: (*a*) after nine years' ser of which at least six must have been spent in Africa, £1000; (*b*) after twelve years' service, of w at least eight must have been spent in East A £1250. If an officer elects to retire with gratuit thereby forgoes all claim to pension.

The highest grades and salaries in the me departments are as follows:—

Kenya, Uganda, and Tanganyika Territor Director of Medical Services, £1500; Deputy Dire of Medical Services, £1200.

Nyasaland.—Director, £1300; Medical Ento logist, £1000–£50–£1100.

Zanzibar.—Director of Medical Services, £1 Resident Surgical Officer, £1000–£50–£1100.

Northern Rhodesia.— Director of Medical Serv £1300; Deputy Director of Medical Services, £1

There are also the following posts: med superintendent and principal of medical school, Mu Hospital (Uganda), £1150; sleeping sickness of (Tanganyika Territory), £1000–£50–£1100; se bacteriologists (Kenya and Uganda), £1000–£ £1100; pathologist (Zanzibar), £600–£1000. Ju surgical specialist (Kenya) and medical speci

(Tanganyika Territory), £600–£1000; Specialist Surgical Officer (Northern Rhodesia), £1100; pathologist (Nyasaland), £600–£920. Health officers are selected from the ranks of medical officers as occasion arises.

Leave of absence on full salary is granted in the normal case after a tour of resident service (varying from 12 to 15 months in Somaliland, 30 to 48 months in Kenya, 20 to 36 months in Northern Rhodesia, and 20 to 30 months in the other East African Dependencies, at the discretion of the Governor). Except in Kenya, Northern Rhodesia, and Somaliland the leave granted amounts to six days for each completed month of residence (or three days when for any reason the officer is not returning to East Africa), exclusive of the periods of the voyages to and from East Africa. Officers serving in certain stations in Nyasaland are allowed five or two and a half days' leave in respect of each month of service instead of six days or three days respectively.

Officers serving in Northern Rhodesia are allowed four days or two days. Officers serving in Somaliland are allowed seven or three and a half days after a tour of 12 to 15 months. Officers serving in Kenya are allowed three days for each month of residential service during their first two tours of service and four days for each month of residence during subsequent tours.

Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given.

Pensions.—Officers on the pensionable establishment may retire on attaining the age of 55 years. Earlier retirement in the event of ill-health is also provided for. Pensions are calculated at the rate of one six-hundredth of pensionable emoluments—i.e., salary and value of free quarters—in respect of each month's pensionable service at the time of retirement, subject in certain cases to an average of emoluments for the last three years before retirement.

WEST AFRICA

Officers hold their appointments in the first instance on probation for three years from the date of their first arrival. After being placed on the permanent establishment this period is counted for pension. Officers are not allowed to take their wives and young children out with them without the sanction of the Governor. When, as is usually the case, an officer has obtained permission to be accompanied by his wife a grant of one-half the cost of his wife's passage to and from West Africa is made subject to certain conditions.

Leave.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service. Within the above limits, the actual length of each officer's tour will be at the discretion of the Governor. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months. In addition, local leave may be granted up to 27 days in any one tour.

The scale of salaries of the officers of the Medical Department, Nigeria, is as follows:—

Appointment.	Salary.	Remarks.
Director of Medical and Sanitary Service.	£1800	Duty allowance £360.
Deputy Director, Health Service.	£1500	Duty allowance £300.
Deputy Director of Medical Service.	£1500	Duty allowance £300.
Specialist Officers ..	£1300	Duty allowance £260. After five years' approved service £1400 with duty allowance £280.
Assistant Director of Medical Service.	£1300	Duty allowance £260.
Assistant Director of Health Service.		
Senior Health Officers..	£1050–£50–£1200	Duty allowance £210.
Senior Medical Officers	£1000–£50–£1150	Seniority allowance £100.
Deputy Director, Tsetse Investigation.	£800–£40–£960	Staff pay £150: Seniority allowance £72.
Senior Sleeping Sickness Officer.		
Research Medical Officer		
Superintendent, Dispensers' Training School.		
Pathologists	£660–£30–£720–£40–£960	—
Medical Officers of Health.		
Medical Officers ..		
Lady Medical Officers..		

The highest grades and salaries in the other West African medical departments are as follows:—

The Gambia.—Senior Medical Officer, £1000–£50–£1150 plus £150 staff pay.

Sierra Leone.—Director, Medical Services, £1400; Surgical Specialist, £1300; Assistant Director of Health Service, £1300.

The Gold Coast.—Director, Medical Services, £1600; Deputy Director of Medical Service, £1400; Deputy Director of Health Service, £1400; Specialist Officers, £1300.

The salary of a medical officer is at the rate of £660 a year, rising by annual increments of £30 to £720 a year. Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £72 a year. Before passing £800, medical officers are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year. A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for senior medical officers).

Research and Pathology.—There are a number of appointments for pathologists in Nigeria and the Gold Coast. The salary and other conditions attached to these posts are similar to those of medical officers of health.

African Medical Officers.—There are a number of Government appointments for African medical officers in the West African Colonies. These appointments carry a salary on the scales of £500–£25–£600 and £600–£30–£720. In addition, in Nigeria and on the Gold Coast, arrangements have been made for the employment of a few young African medical men temporarily on the hospital staffs, with a view to appointment to the Government service later, if suitable. In such cases a salary of £400 a year is paid.

Eastern Colonies and Protectorates

MALAYA

Medical officers are appointed on the following scale of salaries: £700, rising to £770 during three years' probation; then, if they are placed on the pensionable establishment, rising to £805, and thence by annual increments of £35 to £1120, with a strict efficiency bar at £840.

Above the concluding figure of £1120 there are certain higher appointments, as follows: director of medical services, Straits Settlements, £1890; director, Institute for Medical Research, Federated Malay States, and principal, King Edward VII. College of Medicine, Singapore, £1540 each; some posts at £1470; and some posts at £1190, rising annually by £42 to £1400. Salaries are paid in dollars at *2s. 4d.*

Information about general conditions in Malaya is obtainable from the Malayan Information Agency, 57, Charing Cross, London, S.W.1.

Leave.—Eight months' full-pay leave is normally granted: (*a*) after a tour of four years' resident service during the first eight years of resident service; (*b*) after a tour of three years' resident service during the next six years of resident service; (*c*) after a tour of two and a half years' resident service after 14 years' resident service. Additional leave on half-pay may be granted on special grounds. Officers are provided with free passages on first appointment for themselves and their families (i.e., wife and children) up to five persons, inclusive of the officer. On completion of each full tour, free return passages are given to all officers (with wife and children under the age of 10).

HONG-KONG

Officers are appointed on probation for three years. A diploma of public health is required for appointment as a health officer. The scale of salaries of the medical department is: director of medical and sanitary services, £1500–£50–£1800; deputy director £1300–£50–£1400; senior medical officer and senior health officer, £1200 – £40 – £1280; malariologist, bacteriologist, each £920–£40–£1280; port health officer and second port health officer, £860–£40 and one of £20 to £1280; health officers, £860–£40–£1220; assistant bacteriologist, radiologist, each £860–£40–£1220; medical officers, £700–£40–£1180. The currency of Hong-Kong is based on the silver dollar. For purposes of local payment salaries fixed in sterling are converted into dollars at the current rate of exchange. If furnished or unfurnished quarters are provided a rental of 7 per cent. or 6 per cent. on salary respectively is charged. In certain instances a rent allowance is paid instead.

West Indian Colonies

Jamaica.—District medical officers, if on a whole-time basis, draw £600–£25–£800 with travelling allowance and unfurnished quarters or an allowance in lieu. The public hospital, Kingston, has a staff of seven, the senior medical officer drawing £700–£50–£800. The chief post in the colony is that of superintending medical officer, £1000–£50–£1200. Whole-time officers are not allowed private practice. The age for voluntary retirement is 60. Pension is reckoned at the rate of 1-720th of pensionable emoluments for each month of service.

Trinidad and Tobago.—In Trinidad and Tobago Government medical officers receive salary at the rate of £400 per annum, rising by annual increments of £25 to £600. An officer appointed to a district receives, in addition to his salary, a travelling allowance varying from £100 per annum in a normal district to £150 per annum, and is allowed private practice, for which there is good scope. Officers employed in institution work receive a duty allowance varying from £50 to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). The senior medical officer, Grenada, receives £750, The senior medical officer, St. Lucia, receives £650, plus transport and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. The senior medical officer, St. Vincent, receives £500–£600, with free quarters valued at £40. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government are, in Grenada, on the scale £500–£600, in St. Lucia, £400–£500, in St. Vincent, £400–£450. The Governor has the power to transfer a medical officer from one island to another. Appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are similar in number and character to those in the Windward Islands, and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £340, and is later appointed to a definite district at a salary varying from £340 to £400–£25–£450, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands. The medical officers, except in St. Christopher and Nevis, receive fees for successful vaccinations, post-mortem examinations, evidence at courts of justice, and certificates of lunacy. They are also, as a rule, allowed private practice.

British Guiana.—There are the following appointments in the medical service of the colony: surgeon-general, £1000–£1200 per annum, with consulting practice; resident surgeon and surgeon specialist, Georgetown, £1100; ophthalmologist, £700; medical superintendent, Leprosy Hospital, £700; 27 medical officers, £500–£25–£700. Most of the senior posts in institutions carry duty allowances (varying from £50 to £300 per annum) and quarters.

British Honduras.—The salary of an assistant medical officer is £500–£25–£650. The senior medical officer draws £1000, paid in dollars. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The appointments are pensionable.

In British Guiana, Jamaica, and Trinidad officers are allowed to accumulate full-pay leave (at the rate of six weeks for each year's service) up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay may be taken in addition to six months' full-pay leave.

Western Pacific

Fiji.—The chief medical officer receives £1000–£50–£1100, with free unfurnished quarters; the medical superintendent, Colonial War Memorial Hospital, £800–£25–£1000, and free quarters; the medical superintendent, Leper Asylum, £500–£25–£725, with completely furnished quarters and one servant; the medical officer of health, £750–£25–£900, no quarters provided. District medical officers receive £500–£25–£725, with partly furnished quarters or £50 house allowance (at the option of the Government). In certain districts horse allowances or car allowances are granted. In others a medical officer is provided with a launch or boat. District medical officers are allowed private practice on the understanding that their official duties are not neglected. In some districts the medical officer is also district commissioner and receives an additional allowance of from £175 to £235 and free partly furnished quarters. In most districts there is private practice, the value of which has been estimated at from £100 to £600 a year.

Western Pacific.—The staff in the British Solomons Islands Protectorate consists of a senior medical officer, £700–£50–£900, with partly furnished quarters and a local allowance of £50; one travelling medical officer, £550–£25–£650, with partly furnished quarters, a local allowance of £50, and a consolidated travelling allowance of £200.

In the *Gilbert and Ellice Islands Colony* there is a senior medical officer, £650–£25–£750, and an allowance of £100 to compensate for absence of private practice; partly furnished quarters are provided. One medical officer at £600–£25–£650, one at £700–£25–£800. Both these officers receive an allowance of £100 to compensate for absence of private practice; partly furnished quarters are provided.

Mediterranean Colonies

Cyprus.—There is a senior medical officer, £1000–£25–£1200; district medical officers, £400–£20–£600, one of whom is allowed full private practice, and another consulting practice. The surgeon specialist, £600–£25–£750, is allowed consulting practice.

Gibraltar.—The senior medical officer receives £1000. There are 2 medical officers, one at £600–£30–£720 and one at £500–£25–£600–£50–£700. Both are allowed private consulting practice only. Free unfurnished quarters are provided.

Island Group

Falkland Islands.—The senior medical officer is paid at the rate of £800 per annum, with free furnished quarters and £200 in lieu of private practice. Two medical officers receive £700–£25–£800 and £600–£20–£700 respectively, with quarters. Private practice is not allowed.

Seychelles.—The senior medical officer receives £525 and the resident surgeon £450 per annum, with quarters. There are three assistant medical officers, one receiving £450, the other £225 per annum, paid in rupees. Private practice is allowed.

St. Helena.—The senior medical officer receives £550, with fees estimated at £20, and £30 transport allowance. Private practice is allowed. There is a second medical officer at £500.

Middle East

Palestine.—The grades and salaries of higher appointments in the department of health are: director of medical services, £1200, plus £200 expatriation allowance. Deputy director, £850–£50–£1100, plus £150 expatriation allowance; specialist surgeon (who is allowed a certain amount of private practice), and senior medical officers, £800–£25–£1000, plus £100 expatriation allowance. Government analyst, £300–£25–£800, plus £100 expatriation allowance. Payment is in Palestinian pounds, now equal to sterling. The remainder of the staff is recruited locally. Three months' leave with full pay can be taken every two years. Most of the senior appointments have been or will be made pensionable.

APPOINTMENTS NOT WITHIN THE COLONIAL SERVICE

Appointments in the self-governing Dominions and the territories administered by them—viz., Canada, the Commonwealth of Australia (including Papua, Norfolk Island, and the mandated territory of New Guinea), New Zealand (including the Cook Islands and the mandated territory of Samoa), the Union of South Africa (including the mandated territory of South West Africa), the Irish Free State, and Newfoundland—are entirely under the control of the respective Dominion Governments. For information with regard to them application should be made to the High Commissioners or Agents-General in London.

Sudan Medical Service

This service is responsible for carrying out civil and military medical and public health duties in the Sudan.

The staff consists of: (*a*) A director. (*b*) A senior physician and a senior surgeon to the Khartoum Civil Hospital. (*c*) An assistant director. (*d*) Medical officer of health, Khartoum Province. (*e*) 34 British "senior medical inspectors" and "medical inspectors" whose pay commences at £E.720 and rises, subject to the recommendation of the director, by five biennial increases to £E.1080, and after 13 years' service to £E.1200. All rates of pay are subject to an abatement of 7½%. The senior medical inspectors are eligible, by selection, for the senior posts. All medical inspectors are appointed, in the first place, on probation for two years, and if at the end of that time they are accepted for permanent service under the Sudan Government, the first increase of pay is subject to their passing an examination in Arabic.

In addition to the above there are (*f*) a number of medical officers trained at one of the Syrian medical schools, and (*g*) Sudanese medical officers trained at the school of medicine at Khartoum. There are several native (*h*) assistant medical officers, who have been given a purely practical training in one of the larger hospitals in the Sudan.

Amongst the attractions of the service are: The great variety of the work met with among many different races of the Sudan; *leave* of 90 days, generally granted every year after the first 18 months of service; *study-leave*, which may be given for some definite purpose. The pension for medical inspectors who retire after 20 years' service is not less than £E.500 a year. If, however, he serves for a longer period, or is appointed to one of the higher posts, he will receive a larger pension. Private practice is allowed, but is limited to a few of the larger towns, and may be carried on so long as it does not interfere, in any way, with official duties. These duties include acting as consultant to the principal hospitals and the supervision of medical and public health work, the inspection of schools, the examination of candidates for Government service and pension, and the training of assistant medical officers and native sanitary overseers. The Khartoum Medical School is staffed mainly by members of the medical service, who receive additional remuneration for their work as teachers. A registrar of the medical school is also selected from the service, who receives £E.250 a year extra pay.

Inquiries for further information should be made to the Deans of the Principal Medical Schools, and to Dr. Hodson, 69, Harley-street, W.

Southern Rhodesia.—Appointments are under the control of the Government of Southern Rhodesia. Information from the High Commissioner, Crown House, Aldwych, London, W.C.2.

Malta.—Inquiries should be addressed to the Secretary to Government, Valetta, Malta.

North Borneo.—Application to the British North Borneo Company, Staple Hall, Stonehouse Court, Bishopsgate, E.C.3.

Sarawak.—Appointments are in the hands of H.H. the Rajah. Information from the Sarawak Government Offices, 2 Millbank, London, S.W.1.

Basutoland, Swaziland, and the Bechuanaland Protectorate.—Appointments are made upon the recommendation of the resident commissioners, subject to the approval of the High Commissioner for Basutoland, the Bechuanaland Protectorate, and Swaziland, and confirmation by the Secretary of State for Dominion Affairs. These appointments are usually filled by the selection of local candidates.

Shanghai Municipal Appointments.—Inquiries regarding appointments under the Shanghai Municipality, including appointments in the Shanghai Police Force, should be addressed to Messrs. J. Pook and Co., 68, Fenchurch-street, London, E.C.3.

Chinese Maritime Customs.—Inquiries regarding appointments should be addressed to the Inspector-General of the Chinese Maritime Customs, 26, Old Queen-street, London, S.W.1.

Consular Appointments.—Application for appointments of a Consular nature should be addressed to the Foreign Office, London, S.W.1.

Trade Commissionerships.—Applications for appointment as trade commissioner in the colonies and elsewhere should be addressed to the Department of Overseas Trade (Development and Intelligence), 35, Old Queen-street, London, S.W.1.

WOMEN'S MEDICAL SERVICE FOR INDIA

AMONG careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. The Service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. For a further period they are appointed to act temporarily for medical women on furlough. They are then definitely appointed to the charge of hospitals. Private practice is allowed, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcology—are found in the Women's Medical Service. Opportunities are likely to open in the future in connexion with maternity and child welfare.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.300 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

Rates of pay are as follows:—

Years of service.		Overseas allowance per mensem.		Salary per mensem.		English equivalent* per annum.
1 to 3	....	Rs.100	....	Rs.450	....	£440
4 to 6	....	„	....	Rs.500	....	£480
7 to 9	....	„	....	Rs.550	....	£520
10 to 12	....	„	....	Rs.600	....	£560
13 to 15	....	Rs.150	....	Rs.650	....	£600
16 to 18	....	„	....	Rs.700	....	£640
19 to 21	....	„	....	Rs.750	....	£680
22 to 24	....	„	....	Rs.800	....	£720
over 24	....	„	....	Rs.850	....	£760

* At rupee value 1s. 4*d*.

Furnished quarters are provided, representing an additional Rs.150 per mensem.

Leave on average pay is earned at the rate of 2/11ths of the period spent on duty.

Study-leave is granted to the extent of 12 months in the total service and will not be granted more than twice in the course of an officer's service. During study-leave an officer draws half average pay, with a study allowance at the rate of 12*s*. a day during the course of study. Officers of European domicile are entitled to four free return first-class passages from a port in India to a port outside India in their whole service. The first passage is not granted until after the expiry of four years' approved service, and thereafter passages may be granted at intervals of not less than four years. There is a Provident Fund to which members of the Service contribute 10 per cent. of their pay. The Service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the Service is made by selection in India and England—preference being given to those with Indian experience. Vacancies are few. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of India Office, Whitehall, London. Candidates in India should apply to the Chief Medical Officer, Women's Medical Service, Countess of Dufferin's Fund, Simla and Delhi.

THE L.C.C. HOSPITAL SERVICE

THE hospital service of the London County Council provides opportunities for valuable experience for medical graduates who intend to be general practitioners or consultants, as well as for those who intend to make the public health service their career. Under the operation of the Local Government Act, 1929, the L.C.C. became responsible for the management of 74 hospitals (excluding mental hospitals)—namely, 28 general hospitals, 17 fever and other infectious diseases hospitals, 6 tuberculosis hospitals and sanatoria, 9 hospitals and convalescent homes for children, 12 hospitals and institutions for chronic sick patients, and 2 colonies for sane epileptics; 2 convalescent hospitals and one hospital for surgical tuberculosis in children were subsequently acquired, making a total of 77.

Medical superintendents of the hospitals, who are expected to be experienced hospital administrators, receive £900 to £1650 a year, corresponding to hospitals varying in accommodation from 160 to 1300 patients. In addition, medical superintendents are provided with an unfurnished house or quarters, with payment by the Council of local and water rates.

The subordinate staff is classified thus:

Grade.	Scale of annual salary.
Deputy Medical Superintendent, Grade I.	£650–£50–£800
Deputy Medical Superintendent, Grade II.	£600–£30–£750
Senior Assistant Medical Officer, Grade I. .	£550–£25–£650
Senior Assistant Medical Officer, Grade II.	£500–£25–£600
Assistant Medical Officer, Grade I. .. rising to £150 if placed on promotion list.	£350–£25–£425
Assistant Medical Officer, Grade II. ..	£250 (fixed)

In addition all these officers are provided with board, lodging, and washing. All the positions mentioned involve full-time duties, and it is a condition of service that such officers shall not undertake any other paid employment. The staffing provides, where necessary, for house physicians or house surgeons, remunerated at the rate of £120 a year, with residence, and for clinical assistants, who are non-resident and receive £150 a year, with meals when on duty. These officers are not employed in a whole-time capacity and are granted adequate leisure for study.

Deputy medical superintendents and senior assistant medical officers who occupy unfurnished houses or quarters (married quarters) in the hospitals are paid the following salaries in lieu of those set out above. The unfurnished houses or quarters are provided free of charge, the Council also paying all local and water rates:—

Grade.	Scale of annual salary.
Deputy Medical Superintendent, Grade I. ..	£700–£50–£850
Deputy Medical Superintendent, Grade II. ..	£650–£30–£800
Senior Assistant Medical Officer, Grade I. ..	£600–£25–£700
Senior Assistant Medical Officer, Grade II. ..	£550–£25–£650

Vacancies in the higher grades are filled, as far as possible, by promotion from the existing staff. All full-time medical staff are allowed liberal annual leave with pay, and full pay during sickness for a reasonable period. For subordinate staff, the extent and fluidity of the hospital service provides unique opportunities for a variety of experience, and facilities exist for specialisation and for officers to follow courses of study outside the service with a view to improving their professional qualifications.

During the past year 155 vacancies have been filled, including 2 positions as medical superintendents, 2 as deputy medical superintendents, 24 as senior assistant medical officers, 98 as assistant medical officers, 28 as house surgeons, house physicians, or clinical assistants, and 1 as medical officer of a children's hospital. During the year also a large number—more than 200—of part-time consultants and specialists have been appointed to the various units and groups of these hospitals. These appointments, which vary from 1 to 6 sessions a week, include physicians, surgeons, obstetricians and gynæcologists, anæsthetists, pædiatrists, neurologists, orthopædists, radiologists, dermatologists, ophthalmologists, urologists, and specialists in ear, nose, and throat.

In addition, other part-time consultants and specialists were employed for special purposes—e.g., venereal diseases specialists, plastic and thoracic surgeons, &c.—and the services were available of a tuberculosis officer at each general hospital having a tuberculosis ward.

Post-graduate facilities.—These are as follow :—

Hammersmith Hospital.—In connexion with the British Postgraduate Medical School, of which a full account is given on pp. 477 and 478.

St. Alfege's Hospital: Facilities are afforded to the Final Fellowship Class of Guy's Hospital to examine selected cases. The demonstration is undertaken by a surgical tutor of the class.

St. Andrew's Hospital: Consultant surgeon holds weekly classes for two periods of about 10 weeks previous to Final F.R.C.S. examinations.

St. James' Hospital: The South-West London Post-Graduate Association has its headquarters at this hospital where three sessions of lectures are given annually—Autumn, Lent, and Summer.

Post-graduate courses.—Courses of instruction in hospital administration for candidates for the Diploma in Public Health are held at the North-Western Hospital and at the Brook Hospital.

Special Units.—Special departments for the treatment of various diseases are available in the general hospitals and include—e.g., special units at St. James' Hospital for the treatment of cases by plastic surgery and thoracic surgery; at St. Andrew's Hospital for treatment by thoracic surgery; at Lambeth Hospital for the treatment of patients by radium and deep X ray therapy; at New End Hospital for treatment of patients suffering from thyroid disease; at St. Stephen's Hospital, rheumatic cases; at St. Mary, Islington, Hospital for the treatment of urological disease; and at St. Peter's Hospital for the treatment of diabetes.

Under-graduate facilities.—The following general hospitals are affiliated to medical schools for the purpose of clinical teaching :—

Council's Hospital.	*Medical School.*
St. Charles'	Charing Cross Hospital.
St. Alfege's St. Olave's Lewisham	Guy's Hospital.
St. Giles' Dulwich	King's College Hospital.
Archway	Middlesex Hospital.
St. Mary, Islington Highgate	Royal Free Hospital.
St. Pancras Hackney Bethnal Green	St. Barthlolmew's Hospital.
St. Mary Abbots	St. George's Hospital.
Paddington	St. Mary's Hospital.
Lambeth	St. Thomas's Hospital.
St. Mary, Islington	University College Hospital.
St. Stephen's	Westminster Hospital.

In addition, under-graduates from six medical schools are accepted as resident students at certain general hospitals for instruction in obstetrics.

The fever hospitals provide facilities for under-graduate instruction in infectious disease.

Small-pox.—Provision is also made for demonstrations in the diagnosis and treatment of small-pox for both under-graduate and post-graduate students.

Recognition for examinations.—The majority of the general hospitals are recognised for qualifications for candidature in branch 1 of the University of London M.D. Examination. Ten of the general hospitals are recognised by the British College of Obstetricians and Gynæcologists for candidature for their Diploma and membership.

SPECIAL DIPLOMAS

DIPLOMA IN PUBLIC HEALTH

The following epitomises the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene, or State medicine, as the diploma is variously called. Resolutions and rules, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all branches of study which concern the public health," have been adopted at various times by the General Medical Council, by whom the diploma is registrable and whose rules become binding on the educational bodies concerned.

London School of Hygiene and Tropical Medicine.—The course of study for the Diploma in Public Health will commence on Oct. 1st in the premises in Keppel-street (Gower-street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and classrooms, library, and museum. The course, which will extend over a period of nine months for those prepared to give whole-time study, is designed in compliance with the requirements of the General Medical Council, and will enable students, who wish to do so, to proceed to the academic Diploma in Public Health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with medical officers of health in selected areas, a large number of visits to places of public health interest. The course also includes provision for the necessary instruction in infectious disease and hospital management, lectures and demonstrations on physiology applied to hygiene and industry, medical industrial psychology, and sanitary engineering. A series of lectures by authorities on special subjects are open to members of the medical profession as well as to students of the School. The London County Council, the City of London, and various other bodies have placed their resources at the disposal of the School for teaching purposes.

Royal Institute of Public Health and Institute of Hygiene.—Facilities are offered here (23, Queen-square, London, W.C.1) for students training for the D.P.H. There are well-equipped laboratories where practical instruction is given in chemistry, bacteriology, immunology, and public health subjects, and analyses are undertaken, both chemical and bacteriological, of milk, water, and sewage effluents, providing excellent teaching material.

The Course of Study

A diploma of D.P.H. is granted by the Universities of London, Durham, Birmingham, Wales, Aberdeen, Edinburgh, Glasgow, St. Andrews, Dublin (Trinity College), and the English, Scottish, and Irish Conjoint Boards. The course of study is fairly identical in all the centres, as would be expected for a registrable title. It extends over twelve calendar months, or an academic year of full-time study covering a period of not less than nine calendar months, subsequent to the attainment of a registrable degree or diploma. At several of the universities it is stated that a certain part of the course must be pursued locally, while at others there is a proviso that evidence shall be produced of attendance at courses of institutions approved by the university or licensing body; such particular instruction can be obtained from the centres on application.

At all the centres the course is divided into two Parts and candidates must pass Part I. before proceeding to Part II.

Part I.—The duration of training is about five months, some of the centres stating the period as not less than 280 hours. The usual division of subjects is as follows: Candidates will be admissible to examination on producing evidence of having attended during not less than 280 hours at a recognised institution, practical instruction in (*a*) bacteriology and parasitology (including immunology, serology and medical entomology), especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man; (*b*) chemistry, physics, radiology, and electrology in relation to public health; (*c*) physiology and biochemistry in their application to nutrition and hygiene; (*d*) meteorology and climatology in relation to public health. The examinations are held at most centres twice a year, and the candidates must pass in all the specified subjects at one time.

Part II.—The duration of training consists of instruction during not less than 120 hours at a recognised institution in the following subjects: (*a*) the principles of public health and sanitation; (*b*) epidemiology and vital statistics; (*c*) sanitary law and administration; (*d*) sanitary construction and planning. A second part of the examination includes practical examinations in infectious diseases, food inspection and inspection of premises, dwelling-houses, schools, factories, workshops, bakeries, dairies and cowsheds.

While Part II. of the examination entails the acquirement of similar knowledge at all the centres the details of the training differ at certain points—e.g., where the candidate is using the examination also for obtaining a university degree in public health. Intending candidates must, therefore, apply to the selected centre for information.

DIPLOMA IN TROPICAL MEDICINE

Although a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Hygiene and Tropical Medicine, Keppel-street, Gower-street, London, W.C.; while the University of Edinburgh and the English Conjoint Board grant a diploma.

London School of Hygiene and Tropical Medicine

The course of instruction in tropical medicine and hygiene is divided into two parts: Section A, a three months' course in clinical and laboratory instruction, and Section B, a two months' course in tropical hygiene. Each section can be taken independently of the other, and the examinations of the Conjoint Board follow closely upon the end of the corresponding course of study. This revised course is recognised by the University of London as a course for associate students. The dates of the courses for the session 1935–36 are as follows:—

Section A (Clinical and Laboratory Instruction).—Oct. 1st to Dec. 20th, 1935; Jan. 6th to March 27th, 1936; April 6th to June 26th, 1936.

Section B (Tropical Hygiene).—Jan. 20th to March 20th, 1936; April 20th to June 19th, 1936.

The course of instruction under Section A includes clinical tropical medicine, applied pathology, medical zoology, and elementary bacteriology. Section B* comprises instruction in tropical hygiene, including, in relation to hygiene, bacteriology, medical zoology, anthropology, and vital and medical statistics. Section A is so arranged, in four self-contained groups or blocks, as to allow of the admission of a student at the beginning of any block of work, other than bacteriology, subject to a place in the laboratory being available. Accordingly, applications can be received for admission to the classes in Protozoology and Hæmatology (approximately four weeks), or in Helminthology (approximately four weeks), or in Entomology (approximately three weeks), with, in each case, if the student so wishes, the corresponding clinical demonstrations, instruction in applied pathology, and special lectures. Further, students wishing to attend the clinics and clinical lectures only can do so for any period of four weeks during the course. The instruction in the Division of Clinical Tropical Medicine is given by the medical staff of the Hospital for Tropical Diseases and by visiting lecturers. In this way the resources of the hospitals of the Seamen's Hospital Society at Gordon-street, at the Albert Docks, and elsewhere, become available for the clinical instruction of the students at the School.

Liverpool School of Tropical Medicine

The Liverpool University Diploma of Tropical Medicine (D.T.M.) is open only to those who possess a qualification to practise medicine recognised by the university, and who have been through a full course of instruction at this school. The subjects of examination are (*a*) Parasitology; (*b*) Entomology; (*c*) Tropical Medicine, including Ætiology, Symptoms, Pathology, Diagnosis, and Treatment of Tropical Diseases. The course consists entirely of Practical and Clinical work, given at the Laboratory at the University, and at a recognised hospital in which beds are specially reserved for Tropical Diseases. Applications should be made to the Dean of the Medical Faculty, University of Liverpool.

The University also grants a Diploma in Tropical Hygiene (D.T.H.). The subjects of examination are (*a*) Tropical Hygiene (including Sanitary Engineering, Vital Statistics and Epidemiology, and Applied Parasitology and Entomology; (*b*) Practical Sanitation; (*c*) Bacteriology; (*d*) Chemistry (including Meteorology and Climatology). Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

University of Edinburgh

Candidates for the Diploma in Tropical Medicine and Hygiene must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body, or of other universities or medical schools specially recognised. The course of instruction, comprising a primary and a second course, is given during the autumn and spring terms, October to March, and includes Tropical Hygiene, Bacteriology, Entomology and Parasitology, Diseases of Tropical Climates (systematic and clinical), Tuberculosis, and Venereal Diseases. Provision is made in the University for instruction in all subjects.

The examinations are written, oral, and practical, and are held at the end of the courses: Part I in December, and Part II in March. Candidates are required on the first occasion of presenting themselves for examination in either part to appear for all the subjects of that part. Candidates who fail to pass the entire examination in either part within a period of 12 months after first appearance are required to reappear for all the subjects. The University is included in the list of institutions in which courses of instruction in Tropical Medicine may be taken by officers on appointment to the Colonial Medical Services or during study-leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

English Conjoint Board

The Board conducts an Examination three times a year for the D.T.M. & H. granted by the Royal Colleges—namely, in January, April, and July. The Examination comprises written, oral, and practical examinations in the following subjects: *Section A*, Clinical Tropical Medicine and Surgery; applied Pathology, Zoology, and Elementary Bacteriology.

---

* The Andrew Balfour Memorial Fund provides two studentships in the year, which are available in the form of free tuition in Section B. of the Course.

Section B, Tropical Hygiene, including Epidemiology, Medical Zoology, and Bacteriology in relation to Hygiene. Candidates may enter for either or both Sections of the Examination provided that Section A is taken before Section B. (Candidates who are unsuccessful in Section A will not be debarred from presenting themselves for Section B.) Candidates must give 14 days' notice, in writing, to the Secretary at the Examination Hall, 8–11, Queen-square, London, W.C.1, and produce at the same time the necessary certificates of study (after Dec. 18th, 21 days' notice will be required). Candidates must produce evidence of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery, and of having attended subsequently to obtaining such registrable qualification :—(i) *for admission to Section A:* Practical instruction in Pathology, Protozoology, Helminthology, Entomology, and Bacteriology in an Institution recognised for this purpose, together with the clinical practice of a hospital recognised for the study of Tropical Diseases, during not less than three months; (ii) *for admission to Section B:* Instruction in Tropical Hygiene and Sanitation in an Institution recognised for this purpose during a further period of not less than two months. Graduates (M.B., B.S., or M.D.) in Medicine and Surgery of Indian, Colonial, and foreign Universities recognised by the Examining Board in England, whose degrees are not registrable in this country, may enter for the Examination for the Diploma in Tropical Medicine and Hygiene on fulfilling the conditions in regard to study. These conditions may be modified at the discretion of the Committee of Management in the case of a candidate (*a*) who has been employed in foreign (in the case of Naval Medical Officers, one or more commissions abroad must have been held) or Colonial Medical Service, (*b*) who has been engaged in professional work in tropical countries, (*c*) who produces evidence of having been engaged in original investigations in Tropical Medicine or Hygiene. Further particulars from the Secretary, Examination Hall, Queen-square, London, W.C.1.

DIPLOMA IN PSYCHOLOGICAL MEDICINE

The Universities of London, Durham, Leeds, Manchester, Edinburgh, Dublin (Trinity College), Ireland (National University), and the English Conjoint Board grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

University of London

In London, courses of instruction for the Diploma in Psychological Medicine are given annually at the Maudsley Hospital, Denmark Hill, which is a school of the University of London. The course consists of two parts, commencing in January, and is adapted for the diploma of the Conjoint Board also. Comprehensive courses of instruction in the psychoneuroses, child disorders and delinquency are given at the Institute of Medical Psychology (see p. 536) which is now recognised as a teaching centre for the diploma.

Maudsley Hospital.—Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. A course for the Diploma in Psychological Medicine is held annually from January to June at the Central Pathological Laboratory of the London County Mental Hospitals, which is situated in the Maudsley Hospital. Facilities and grants-in-aid are given for research work in psychiatry and allied subjects at the Laboratory. Inquiries as to lectures should be addressed to the Director of the Medical School, Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.; and as to clinical facilities to the Medical Superintendent at the same address.

Bethlem Royal Hospital.—A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various universities and the Conjoint Board, is held at Bethlem Royal Hospital, Monks Orchard, Eden Park, Beckenham, twice annually, during the spring and autumn when possible. Part A or Part B, however, may be taken separately. In addition to the above, clinical instruction in Psychological Medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A.M. A reduction is made to those who attend the Diploma Course. House physicians are appointed at Bethlem Royal Hospital for a term of six months, which may be extended. These appointments are made at the beginning of February, May, August, and November in each year, and the vacancies are advertised in the medical papers. Apartments, complete board, attendance, and laundry are provided, and a salary at the rate of £150 per annum for the first three months, rising, if commendable service be given, to the rate of £200 per annum for the second period of three months. Clinical assistants are often appointed from time to time for periods of three months or longer. These are non-salaried and non-resident posts, but partial board is provided. The Physician-Superintendent, Bethlem Royal Hospital, Monks Orchard, Eden Park, Beckenham, will supply further particulars; the courses have not yet been arranged.

University of Durham

The university grants a diploma in psychiatry, and at the College of Medicine there is a department of instruction in psychological medicine. The candidate must be a registered medical practitioner, and subsequent to qualification have followed instructions on anatomy and physiology of the brain and nervous system. The examination is divided into two parts, Part I. dealing with anatomy, physiology, pathology, and bacteriology; Part II. with psychology and experimental psychology. Candidates may present themselves for the whole examination or for either part separately. The course of training is very detailed, post-mortem technique being the subject of a series of sessions, the same holding good for psychiatry and experimental psychology.

University of Leeds

The university grants a diploma in psychological medicine to graduates in medicine of at least one year's standing, who can prove that they have received systematic instruction on the normal and morbid anatomy of the brain and have held an appointment in a mental hospital. The examination is divided into three parts: Part I. deals with general psychology and the structural development and physiology of the nervous system; Part II. with the pathology of that system; and Part III. with clinical psychiatry, the administration of mental hospitals, and the medico-legal aspects of insanity. Candidates may present themselves for the three parts simultaneously or separately; they may submit a thesis or published work which, if approved, will gain certain exemptions.

University of Manchester

The university grants a diploma in psychological medicine to graduates of at least one year's standing. The examination is held in two parts. Before presenting themselves for Part I. candidates must, subsequent to qualification, have attended approved courses in the structure of the nervous system and in experimental psychology. Before presenting themselves for Part II. they must produce evidence of having gone through an approved course of instruction in the pathology of the nervous system and in clinical neurology, and of having attended demonstrations in psychological medicine, and received clinical instruction, either as residents or as daily attendants, at an approved hospital for mental diseases. The course extends over a period of three university terms, two of which must be taken in the university, and candidates may present themselves for both parts simultaneously or each separately.

University of Edinburgh

Candidates for the Diploma in Psychiatry must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body, or of other universities or medical schools specially recognised. The course for the Diploma extends over one term and is given from January to March. Candidates are required subsequent to the date of graduation or obtaining a recognised qualification to have held (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty of Medicine, or alternatively (*b*) a six months' appointment as defined in (*a*) and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty of Medicine. There are two examinations for the Diploma both of which are held in March. Part I. comprises: 1. Anatomy of the Nervous System; 2. Physiology of the Nervous System; 3. Psychology and Experimental Psychology. Part II. comprises: 1. Neuropathology; 2. Psychiatry and Clinical Psychiatry; 3. Clinical Neurology; Candidates who have held an asylum appointment for a period of five years or more may be exempted from the course of study in one or more subjects of the curriculum. Full particulars can be obtained from the Dean of the Faculty of Medicine.

University of Dublin (Trinity College)

A post-graduate diploma in Psychological Medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognised institution for the treatment of Mental Diseases for 12 months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Candidates must also attend special courses of instruction and pass a special examination. Details can be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland

This University confers a diploma in Psychological Medicine. The diploma may be conferred on registered medical practitioners who although they may not have matriculated at the University shall have completed the prescribed course of study. A certificate of post-graduate work will be required from the candidates, either in the study of mental disease or as medical assistant in an asylum. Application should be made to the Registrars of the Constituent Colleges, University College, Dublin, University College, Cork, and University College, Galway, for all information.

DIPLOMA IN OPHTHALMIC MEDICINE

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford

The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in June, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' course of clinical ophthalmology at a recognised hospital. Further information regarding these requirements may be obtained from the Dean of the Medical School.

English Conjoint Board

The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in February and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a recognised qualification.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

University of Cambridge

Before admission to any course for the Diploma a candidate shall produce evidence that he holds a medical qualification approved by the committee and also satisfy the committee that he has had sufficient post-graduate clinical experience. The next course, which begins on Oct. 2nd, 1935, occupies nine months. The first four months, which can be spent either in Cambridge or in London, are occupied with (*a*) lectures and practical work in Physics, in preparation for the examination for Part I. in February, (*b*) an introductory course of clinical instruction in Radiology and Electrology, (*c*) a course of instruction in Pathology in relation to Radiology and Electrology. The next three months must be spent in London, and are occupied with (*a*) lectures and demonstrations in Radiology and Electrology (including Radium Therapy) organised by the British Institute of Radiology, (*b*) clinical instruction in the Radiological Department of a hospital approved by the committee. During the final two months of the course a candidate must hold a clinical clerkship or similar appointment in the radiological department of a hospital approved by the committee. This part of the course may be done in London, or elsewhere. The examination for Part II. will be held in July. Further particulars as to courses and examinations may be obtained from Mr. G. Stead, M.A., Secretary for the Diploma, Cavendish Laboratory, Cambridge, or the General Secretary, British Institute of Radiology, 32, Welbeck-street, W.1.

University of London

The course for the post-graduate diploma in Medical Radiology extends over one academic year, and is open to registered medical practitioners and graduates in medicine of this or any other approved University. The subjects are: Part I., Physics and Electro-technology. Part II., (*a*) Radiology and Radio-diagnosis; (*b*) Radiotherapy. The examination is held in March and December (Part I.), and in June and December (Part II.). Particulars may be obtained from the Academic Registrar.

University of Liverpool

Candidates before admission to the examination for the D.M.R.E. must possess a registrable qualification approved by the University in medicine and surgery, and must have attended courses of instruction in (*a*) physics (two terms), (*b*) (i) radiology, and (ii) electrology during nine months in the X ray and electrotherapeutic department of a hospital or hospitals. An examination is held in March and June (Physics) and in June (Radiology and Electrology). Examination in either part may be taken separately. A registration deposit fee of £5 5*s.* is charged on application and credited to the fees, but is not returnable in the event of the candidate failing to register. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

University of Edinburgh

Candidates for the Diploma in Radiology must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications from some other licensing body, or of other universities or medical schools specially recognised. The course of study for the Diploma covers an academic year (9 months) and commences in October. The number of candidates to be admitted to the course is limited, and early application for admission is essential. Candidates are not admitted to the examination for the Diploma until after the lapse of not less than one year from obtaining a recognised qualification. The examination, which is written, oral, and practical, is in two parts: (*a*) Physics, and (*b*) Radiology. Full particulars may be obtained from the Dean of the Faculty of Medicine.

English Conjoint Board

The examination for the D.M.R., R.C.P. and S. comprises Part I. Physics, as applied to Radiology, and Part II. Medical Radiology, with special reference to its clinical application, including Radio-diagnosis, X Ray Therapy, and Radium Therapy. Both examinations, which are written, oral, and practical, are held during January and July. The course of study extends over one academic year of full-time study, subsequent to the attainment of a recognised qualification. Before admission to the examination the following certificates must be produced. For admission to Part I. evidence of having attended a course of instruction in physics as applied to radiology at a recognised medical school or institution for not less than three months. For admission to Part II. evidence of having attended at a recognised hospital courses of instruction, theoretical and practical, in medical radiology, including radio-diagnosis, X ray therapy, and radium therapy, with clinical experience for three terms.

Candidates may enter for Parts I. and II. either together or separately, subject to the production of the required certificates; but no candidate is permitted to proceed to Part II. of the examination until he has passed in Part I. Candidates must give 21 days' notice, in writing, of their intention to present themselves for examination, to the Secretary at the Examination Hall, 8–11, Queen-square, London, W.C.1, forwarding at the same time the necessary certificates of study. The conditions regarding admission to examination may be modified at the discretion of the Committee of Management in the case of a candidate (*a*) who has carried out original investigations in any subject of the examination, or (*b*) whose studies have extended over a prolonged period of time without fulfilling the exact conditions. Exemption will not be granted from any part of the examination.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY

English Conjoint Board

The Board grants the D.L.O. after an examination held in two parts, in June and December. Part I. comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus. Part II. comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification, or a degree in medicine and surgery of a University recognised by the Board.

DIPLOMA IN TUBERCULOUS DISEASES

University of Wales

Candidates may be admitted to examination for the Tuberculosis Diseases Diploma after the lapse of not less than two years, from the date of obtaining a qualification in Medicine, Surgery, and Midwifery, registrable in Great Britain, or in the Dominions, Colonies, and Dependencies of the British Empire. Every candidate must have held a resident post in a Tuberculosis Hospital, or at an Orthopædic Institution providing not fewer than one hundred tuberculosis beds, or shall satisfy the Faculty of Medicine that he has pursued a special study of tuberculosis equivalent to the above for a period of not less than twelve months.

The examination is in two parts. Part I. (*a*) written and (*b*) oral and practical, including the examination of patients, and the recognition of specimens; Part II. is a written and practical examination on the epidemiology, pathology, and bacteriology of tuberculosis. Every candidate will be required to satisfy the examiners in both parts in the same examination. The Course of Instruction commences in January and continues until May each year, when the examinations are held.

A limited number of appointments for part-time Assistant Tuberculosis Physicians are advertised annually in September by the Welsh National Memorial Association, enabling suitably qualified and selected candidates to study for the Diploma. Particulars on application to the Secretary, Welsh National Memorial Association, Memorial Offices, Westgate-street, Cardiff. Further particulars may be obtained from the Secretary The Welsh National School of Medicine, The Parade, Cardiff.

DIPLOMA IN BACTERIOLOGY

University of London

The course of study for the Academic Post-graduate Diploma in Bacteriology extends over one academic year and is open to (*a*) Graduates in Medicine, Science, and Pharmacy of this or another approved University, whose previous training has, in the opinion of the University, fitted them to profit by the Course; and (*b*) registered medical practitioners and other students who, though not graduates, have obtained a qualification and undergone a previous training which, in the opinion of the University, has fitted them to profit by the Course.

A Course necessary to fulfil the regulations of this Diploma has been planned by the London School of Hygiene and Tropical Medicine, Keppel-street, London, W.C., and full particulars with regard to the Diploma may be obtained from the Academic Registrar, University of London, South Kensington, S.W.7.

DIPLOMA IN CLINICAL PATHOLOGY

University of London

The course of study for the Academic Post-graduate Diploma in Clinical Pathology extends over one calendar year, and is open to graduates in Medicine and to registered medical practitioners. The subjects are (1) Morbid Anatomy and Histology; (2) Bacteriology and Serology; (3) Biochemistry. The examination is held in December. Particulars may be obtained from the Academic Registrar, University of London, South Kensington, S.W.7. Particulars of the External Diploma in Clinical Pathology may be obtained from the External Registrar at the same address.

DIPLOMA IN ANÆSTHETICS

English Conjoint Board

Examinations for the new diploma of D.A. will take place twice yearly, in May and November; the first examination will be held on Nov. 8th next. Tests will be written and oral. Subjects include history, theory, and practice of anæsthetics; pharmacology and elementary chemistry of anæsthetic drugs; pre- and post-operative conditions relevant to anæsthesia. A candidate must either have a resident appointment in a recognised gene hospital for twelve months, of which at le shall have been as resident anæsthetist, or have administered anæsthetics in a hospit less than one thousand occasions, at least one-half of which shall have been for major surgical procedures. These conditions may be modified for candidates who have carried out original investigations in the science or practice of anæsthetics or whose studies have extended over a long period without fulfilling the exact conditions. During the next three years the diploma may be granted to anæsthetists of not less than ten years' standing attached to a teaching hospital.

DIPLOMA IN CHILD HEALTH

English Conjoint Board

The first examination for the new diploma of D.C.H. will be held on Oct. 4th, next. The examination (written, oral, and clinical) will comprise the following subjects, special emphasis being laid on their preventive aspects: (*a*) anatomy, physiology, and pathology of childhood; (*b*) development of the child, physical and mental, including speech, with their disorders; physical education in childhood; (*c*) hygiene and dietetics of infancy and childhood; (*d*) affections of the new-born; (*e*) disease in infancy and childhood, medical and surgical; (*f*) therapeutics of infancy and childhood, including remedial treatment, physical and mental; (*g*) legislation and public administration in regard to the care of children, including the methods of infant welfare centres and of the school medical service. The candidate must have been in a recognised children's hospital or department as resident medical officer for six months or as clinical assistant for a year, though these conditions may be modified in the case of candidates who have carried out original research or whose studies and practice have extended over a long period. Forms of application, to be obtained from the secretary, Examination Hall, 8, Queen-square, London, W.C.1, must be returned at least 21 days before the examination.

DENTAL SURGERY

TEACHING INSTITUTIONS IN DENTISTRY

REGISTRATION on the Medical Register entitles a practitioner to practise dentistry, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma, and, until registered on the Dentists Register, no dental work under the Additional Benefit Scheme of the National Health Insurance Act can be undertaken.

The Examining Bodies in Dentistry which grant degrees and diplomas in the subject are as follows: Royal College of Surgeons of England, Royal College of Surgeons, Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow, Royal College of Surgeons in Ireland, and the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, St. Andrews, Dublin (Trinity College), Queen's University of Belfast, and the National University of Ireland. The student should apply to the secretaries of the various Conjoint Boards or to the Deans of the medical faculties or medical schools for a syllabus.

TEACHING INSTITUTIONS IN LONDON

Royal Dental Hospital

The Royal Dental Hospital of London, School of Dental Surgery, Leicester-square, is a school of the University of London. The school provides the special dental education required by the University of London for the B.D.S. Degree and the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 6 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructor at the commencement of each session gives a course of lectures on Operative Dental Surgery. The two senior house surgeoncies and the six house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Scholarship in Dental Mechanics and Metallurgy, value £25. For full information as to scholarships and prizes, and other matters connected with the course, application should be made to the Dean.

University College Hospital Dental School

This Hospital and School, situated at the corner of Great Portland and Devonshire-streets, W., has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the *National Dental Hospital*—the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A prospectus containing full information as to lectures, fees, and prizes may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University-street, W.C.1, on Wednesday mornings from 9.30 to 10.30, and at other times by appointment.

Guy's Hospital Dental School

The work of the Dental Department begins daily at 9 A.M. both in the anæsthetic rooms and in the conservation room. The Extraction Rooms have now been entirely reconstructed. There is ample accommodation for extractions, both with general and local anæsthetics, together with waiting and recovery rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M., and is under the charge of the Director aided by the assistant to the Director. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for denture patients affording accommodation for 15 chairs and a separate department for children with accommodation for 20 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by the Director of the Conservation Room together with his Assistant, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study by the Staff Demonstrators. Students in Dental Prosthetics are occupied with this subject for two years, during which time a graded, systematic, and full course of instruction is given under the supervision of the Director of the Prosthetic Laboratory, assisted by four demonstrators, a house surgeon, and skilled mechanics.

Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. Students who enter for a medical as well as a dental course are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves.

Fourteen house surgeons, 20 assistant house surgeons, and 4 student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, dresser in the children's department, casualty dresser, dresser to the director of the conservation room, probationary dresser, clerk to the anæsthetist and dresser in the general anæsthetic and local anæsthetic rooms. Two Entrance Scholarships are awarded annually in April as follows: (1) A War Memorial Scholarship in Arts of the value of £40 per annum for four years, open to students under 19 years of age. Candidates are required to take English and any two of the following subjects: French, German, Latin, Greek, and Mathematics. (2) A Science Scholarship of the value of £40 per annum for four years, open to students under 20 years of age. Candidates are required to take two of the following subjects: Chemistry, Physics, and Biology. Further information will be supplied by the Dean of the Medical School.

King's College Hospital Dental School

The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-patient Department of the Hospital is used for the performance of dental extractions. A large Conservation Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in dental mechanics. An X ray apparatus has been installed for use in dental skiagraphy. The Dental museum contains a large number of specimens illustrating oral, buccal, dental, and other diseases. The library, lecture theatre, lecture rooms, common rooms, and the refectory are all available for the use of students. Courses of study, including practical work, are provided for the degree of Bachelor of Dental Surgery of the University of London, and for the Diploma in Dental Surgery of the Royal College of Surgeons of England. Special arrangements can be made for those students who wish to take a medical degree or qualification in addition to a degree or diploma in Dental Surgery.

The following salaried appointments are open to qualified members of the School: Registrar, Resident House Surgeon, Non-Resident House Surgeon, and Tutors in Dental Mechanics, Operative Dental Surgery, and Dental Materia Medica.

Full particulars of the Dental School may be obtained on application to the Dean, or to the Secretary of the Medical School, King's College Hospital, Denmark Hill, London, S.E.5.

London Hospital Dental School

This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated, and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the student's cabinet. Electric sterilisers are supplied in each department and motor engines where required. The school possesses, in addition to the Theatres, Laboratories, and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, an X Ray Room, and Laboratories for Practical Metallurgy and Prosthesis. A systematic course of instruction is arranged for pupils. The up-to-date Laboratory contains every modern apparatus, and is in charge of a skilled curator and his assistants. Entrance Scholarship: Francis Farmer Entrance Scholarship in Science, value £25; no age limit. Subjects: Chemistry and Physics. Prizes: The Harold Fink Prize in Operative Dental Surgery, value £8 8s.; the "London" Prize in Dental Prosthesis, value £6 6s. Prizes are also offered for competition at the end of each of the courses of lectures in the curriculum. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, and an Athletic Ground. A new Residential Hostel has been opened, and provides accommodation for upwards of 50 students. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean of the Medical School.

TEACHING INSTITUTIONS OUTSIDE LONDON

Birmingham Dental Hospital

The Dental Hospital in Great Charles-street has accommodation for 100 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery, including Radiology and a department for Practical Pathology and Bacteriology. The hospital, both internally and externally, has been renovated, and several departments have been reconstructed. The operations performed annually average 70,000, including gold and other fillings, crowns, bridges, porcelain inlays, jacket crowns, and injections for block and infiltration anæsthesia. The orthodontic department is one of the foremost in the country. The prosthetic and mechanical department is large and well lighted and two highly skilled instructors are always present, while two honorary officers give daily demonstrations. Application for information as to fees and scholarships must be sent to the Dean of the Medical Faculty, Birmingham University, or the Dean of the Dental Hospital, Birmingham.

Leeds University School of Dentistry

The School of Dentistry is adequately equipped to provide for the complete training of the dental student. It forms a part of the Leeds School of Medicine whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital. The School is now in occupation of a spacious new building especially designed to the requirements of modern dental teaching. The School is also the dental department of the General Infirmary, and its close association with the work of that institution ensures an adequate supply of clinical material, and enables a fuller insight into the position dental surgery holds in relation to general medicine and surgery, especially with regard to the major diseases and injuries of the head and neck. The courses of study are mainly designed to meet the requirements of the B.Ch.D. and L.D.S. Leeds, but every opportunity is afforded to students preparing for the degrees or diplomas of other licensing bodies. Full-time teachers give the instruction in clinical dental surgery, prosthetic dentistry, and mechanics, which is carried out under the supervision and direction of the Professor of Clinical Dental Surgery and members of the Honorary Staff. Special facilities are provided for instruction in Orthodontia, Radiography, Local and General Anæsthetics, and Bacteriology. Prizes are offered for competition to students in their respective years of study. Post-graduate clinical courses are arranged in collaboration with the Dental

Board of the United Kingdom, and facilities exist to meet the requirements of dental surgeons desirous of obtaining special post-graduate instruction. Communications should be addressed to the Warden, School of Dentistry, Leeds, from whom a prospectus may be obtained.

University of Manchester School of Dental Surgery

Courses of study are provided to meet the requirements for the B.D.S. Degree and the L.D.S. Diploma of the University of Manchester, and for the L.D.S. Diploma of the Royal College of Surgeons of England. At the Dental Hospital instruction is given in practical Dental Mechanics, Operative Dentistry, Diagnosis and Extraction, Orthodontics, Dental Prosthetics, Anæsthetics, and Radiography by specially appointed Clinical Teachers. All the courses of instruction are open to women students. Copies of the prospectus may be obtained on application to the Dean.

Newcastle-upon-Tyne Dental Hospital and Sutherland Dental School

This institution is a component part of, and constitutes the Dental Department in, the University of Durham College of Medicine. A dental hospital, erected within the grounds of the Royal Victoria Infirmary and equipped with the most modern apparatus, was opened in 1932, and it is possible to undertake the whole of the dental curriculum—i.e., systematic lectures, dental and general hospital practice, together with the mechanical pupilage—at the College. The Dental Board of the United Kingdom recognises the school for the purpose of granting its bursaries to students who are able to comply with the conditions laid down by the Board. The composition fees payable by dental students are £90 for all systematic lectures and laboratory work at the College for the B.D.S. (or £85 for the L.D.S.), £50 for dental hospital practice for B.D.S. (or £40 for L.D.S.), £16 16s. for general hospital practice, and £80 for pupilage in mechanics. A dental prospectus and any other information may be obtained from the Dean, University of Durham College of Medicine, Newcastle-upon-Tyne.

SCOTTISH TEACHING INSTITUTIONS

Edinburgh Dental Hospital and School

The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Registrar.

Incorporated Glasgow Dental Hospital

This hospital is located at 211, Renfrew-street, Glasgow. The school is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extramural schools where special provision is made for Dental Students. The new Dental Hospital is now open and is equipped with all the modern methods for teaching students. Post-graduate courses will be inaugurated during the coming winter.

Glasgow Royal Infirmary

Dental Department: The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months. Clinical Medicine (three months) and Clinical Surgery (six months) are taken at the Royal Infirmary.

IRISH TEACHING INSTITUTION

Dental Hospital of Ireland

All Dental Students who have passed their Second Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Post-graduate courses are given in Orthodontics. Further particulars can be obtained from the Dean, at Lincoln-place, Dublin.

Diploma in Psychological Medicine: University of London

Addendum to p. 531

The course of training arranged by the INSTITUTE OF MEDICAL PSYCHOLOGY, Malet-place, London, W.C. (formerly the Tavistock Square Clinic for Functional Nervous Disorders) is not intended to cover the whole field of mental illness. For the purposes of the University of London Post-graduate Diploma in Psychological Medicine, it provides facilities for the practice in Psychoneuroses and Early Psychoses and in Mental Retardation and Delinquency required under Regulation 3, Section II. (*d*) and (*c*) for this Diploma.

There are post-graduate courses in psychotherapeutic theory and method. The main course, covering one year's work, is arranged for two groups; (*a*) those who can only manage to devote three hours twice a week; (*b*) those who, with a view to specialisation, are prepared to give as a minimum twelve hours a week (attending on three days). The course is limited to a membership of twelve practitioners. In addition there is a five weeks' introductory course of lectures with case discussions and ten tutorials on Child Guidance (or Mental Health in Childhood). Systematic Lectures are given twice a week throughout the year.

These courses form part of the one year's course in psychotherapeutic theory and method, but may be attended by qualified medical practitioners who wish to take them as isolated courses of lectures. Week-end courses will be given at intervals during the year. A short course on the Psychoneuroses, intended for those with some knowledge of elementary principles will be given for one fortnight in the Summer.

Notes, Comments, and Abstracts

A HUNGARIAN STUDENTS' NUMBER

A SPECIAL number of the *Orvosképzés* contains articles on various aspects of medical education by all the prominent teachers of the Budapest school; some of them are swan-songs, for they are written by distinguished men now retiring under the age limit. The variety of languages is noteworthy; of the signed articles 21 are in Magyar, 20 in German, 5 in French, 3 in English, and 1 in Italian. Two prefatory articles are by outsiders. Prof. A. Eiselsberg (Vienna) writes on medical education and Prof. Ludwig Aschoff (Freiburg i. Br.) on the new outlook of medical teaching in Germany. Eiselsberg laments that Latin should be dropping out of medicine. In the 'fifties Billroth lectured to his Greifswald students in Latin, and at Göttingen Latin was spoken in the clinic, partly out of consideration for patients' feelings. Although national pride might make this no longer feasible, enough Latin must be retained for the student to find his way about medical terminology. Eiselsberg spoke (of course) of overcrowding in the medical curriculum which was still a problem in Vienna, although such ballast as materia medica had long been dropped and the "free-will" year which before the war more than half the Viennese medical students were obliged to put in was now available for other purposes. Prolongation of the curriculum was out of the question; he saw nothing for it but to shorten the vacations. He spoke with pride of the course of general pathology; Vienna stood alone in having a special institute for the purpose in which morbid anatomist, clinician, and pharmacologist were associated. Finally he expressed anxiety at the excessive number of students still qualifying in medicine. Last year 203 Austrians took their M.D., only 42 less for little Austria than the 245 who qualified in 1914–15 to serve the great Austrian confederacy of States. It was, he feared, not so much the attraction of medicine as the lack of other openings which was responsible for this, and he spoke with horror of the three sons of a porter at a railway station in the neighbourhood of his own home who were all studying at the university. Aschoff set out his conception of general pathology on which the whole of the medical course should turn, and he claimed that such a course was at present only given in German-speaking and related countries. More and more, he said, was he convinced that the medical man of the future must be trained in biology.

M.D. DEGREES OF SWISS UNIVERSITIES.—The Universities of Basle, Bern, Geneva, Lausanne, and Zürich grant the degree of Doctor of Medicine to "medical practitioners from other countries who are legally entitled to practise in their country of origin" under the following *conditions*: 1. Pursue a course of study in the final subjects of the medical curriculum, and pass a viva-voce examination in such, at the end of one academic year (nine months). 2. Prepare at the same time a thesis for the doctorate, which has to be accepted by the Faculty of Medicine towards the end of the year. The total fees (examination and diploma) amount to Fr.450 Swiss (£25). At Lausanne there is a tutor for British practitioners. At Geneva and Lausanne a laboratory or clinical course is so arranged that it provides the subject matter for the thesis, which is prepared during the entire stay. The candidate should make written application to the Dean of the Faculty of Medicine, and further information can be obtained in this country from the hon. secretary of the Lausanne Medical Graduates' Association (Dr. Charles Franklyn, The Corner House, Queensway, Lincoln).

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. R. E. Rampling to *Arethusa*, and as Squadron Medical Officer (on transfer of flag).

Surg. Lt.-Comdr. M. Barton promoted to rank of Surg. Comdr. and Surg. Lt. A. M. Lawrence-Smith to rank of Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Sub-Lts. K. E. O. Ringdahl promoted to Surg. Lt., and L. S. Anderson (proby.) to *Iron Duke*.

H. J. Wade entered as Proby. Surg. Lt.

Proby. Surg. Sub-Lt. S. E. Cooke to *Rodney*.

ARMY MEDICAL SERVICES

Col. G. S. Wallace, O.B.E., late R.A.M.C., having attained the age for retirement, is placed on ret. pay.

Lt.-Col. and Bt. Col. F. Casement, D.S.O., from R.A.M.C., to be Col.

Col. G. S. Wallace, O.B.E., late R.A.M.C., relinquishes the appt. of Professor of Hygiene, Royal Army Medical College.

Col. W. B. Purdon, D.S.O., O.B.E., M.C., late R.A.M.C., to be Professor of Hygiene.

ROYAL ARMY MEDICAL CORPS

Maj. H. C. D. Rankin, O.B.E., to be Lt.-Col.

Short Serv. Commissions.—Lt. (on prob.) A. H. T. F. Fullerton is secd. under the provisions of Art. 213, Royal Warrant for Pay and Promotion, 1931.

H. C. George to be Lt. (on prob.).

ROYAL AIR FORCE

Flying Offrs. R. G. James to R.A.F. Station, Mount Batten, and A. R. C. Young to No. 3 Flying Training School, Grantham.

INDIAN MEDICAL SERVICE

Lts. (on prob.) to be Capts. (on prob.): M. G. Leane, G. E. S. Stewart, and D. P. Dewe.

The appointments of the undermentioned officers are confirmed:—

Lts. (now Capts.): W. J. Virgin, J. Brebner, H. W. G. Staunton, J. D. Gray, D. W. Taylor, P. H. Addison, J. W. D. Goodall, F. J. Doherty, and S. G. O'Neill.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 17TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1365; diphtheria, 870; enteric fever, 64; acute pneumonia (primary or influenzal), 484; puerperal fever, 40; puerperal pyrexia, 106; cerebro-spinal fever, 7; acute poliomyelitis, 34; acute polio-encephalitis, 3; encephalitis lethargica, 15; dysentery, 17; ophthalmia neonatorum, 82. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 23rd was 2552, which included: Scarlet fever, 741; diphtheria, 913; measles, 32; whooping-cough, 432; puerperal fever, 15 mothers (plus 0 babies); encephalitis lethargica, 270; poliomyelitis, 13. At St. Margaret's Hospital there were 21 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 13 (0) from measles, 7 (2) from scarlet fever, 16 (3) from whooping-cough, 22 (1) from diphtheria, 64 (10) from diarrhœa and enteritis under two years, and 14 (3) from influenza. The figures in parentheses are those for London itself.

Deaths from diarrhœa and enteritis were scattered over 30 great towns, the highest numbers being Liverpool and Birmingham each 9, Hull 4, Birkenhead 3, no other great town more than 2. Liverpool also reported 7 deaths from measles, Birmingham 2. Fatal cases of diphtheria were reported from Liverpool 5, Warrington and Birmingham each 3.

The number of stillbirths notified during the week was 284 (corresponding to a rate of 39 per 1000 total births), including 39 in London.

Appointments

Certifying Surgeons under the Factory and Workshop Acts: Dr. N. R. CUNNINGHAM (Bradford, West, County of York (West Riding)); Dr. A. A. HEATHCOTE (Newport, Isle of Wight); Dr. C. G. Walker (Oxted, Surrey).

Vacancies

For further information refer to the advertisement columns

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

All Saints' Hospital for Genito-Urinary Diseases, Austral-street, S.E.—Res. H.S. At rate of £100–£150.

Bedford County Hospital.—First H.S. At rate of £155.

Belfast, Forster Green Hospital for Consumption and Chest Diseases.—H.P. At rate of £150.

Belfast, Royal Maternity Hospital.—Two Res. H.S.'s. At rate of £100 and £52 respectively.

Blackburn County Borough.—Asst. M.O.H. £600.

Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £150.

Bristol Eye Hospital.—Jun. Res. H.S. £100.

Bristol, Frenchay Park Children's Orthopædic Hospital and Sanatorium.—Res. M.O. £250.

Cancer Hospital, Fulham-road, S.W.—Asst. Radiologist. £350. Also H.S. At rate of £100.

Central London Throat, Nose, c [illegible] *road, W.C.*—Hon. Assts. to [illegible]

Ceylon, Colombo Municipal [illegible] Rs.12,000/- a year.

Chester Royal Infirmary.—H.S. for Special Depts. £150.

Chichester, West Sussex County Mental Hospital.—Third Asst. M.O. £350.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose and Throat Depts. £175.

Doncaster Royal Infirmary and Dispensary.—Sen. Res. £250. Also Res. Anæsthetist. At rate of £175.

Downpatrick, Down Mental Hospital.—Asst. M.O. £300.

Dreadnought Hospital, Greenwich, S.E.—Receiving Room Officer and H.P. At rate of £200 and £110 respectively. Also H.S. At rate of £110.

Dudley, Guest Hospital.—H.S. and Second H.S. £200 and £170 respectively.

East Ham Memorial Hospital.—Pathologist. £300.

Enfield U.D.C.—Asst. M.O.H. and Asst. School M.O. £600.

Exeter, Royal Devon and Exeter Hospital.—H.P. Also H.S. to Ear, Nose, and Throat Dept. Each at rate of £150.

Gloucestershire Royal Infirmary and Eye Institution.—Res. Surg. O. At rate of £200.

Great Yarmouth General Hospital.—H.S. £140.

Hammersmith Hospital, Ducane-road, W.—Asst. Radiologist. £700.

Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—Cas. M.O. for Out-patient Dept. At rate of £100.

Hastings, Royal East Sussex Hospital.—Hon. Anæsthetist. Also Locum H.S. £5 5*s.* per week.

[illegible] *Hospital.*—H.P., and H.S. and Cas. O.

[illegible] *en, Great Ormond-street, W.C.*—Research [illegible]

[illegible] At rate of £150.

[illegible] *Kirkburton.*—Fifth Asst. M.O. [illegible]

Leicester Royal Infirmary.—H.S.'s, Cas. O., H.P.'s, Jun. Res. Anæsthetist. Each at rate of £125. Also Jun. Cas. O. At rate of £100.

Liverpool, County Mental Hospital, Rainhill.—First and Second Asst. M.O.'s. £700 and £650 respectively.

Liverpool Royal Children's Hospital.—Res. M.O. for Heswall Branch. At rate of £120.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Second Asst. to Med. Supt. £200.

London Lock Hospital, 283, Harrow-road, W.—Res. M.O. to Female Depts. At rate of £175.

Lowestoft Borough.—Consultant Obstetrician. £3 3*s.* per [illegible]

[illegible] *nfirmary.*—Second H.S. £150.

[illegible] *hildren's Hospital, Garlside-street.*—Two [illegible] h at rate of £150.

[illegible] *y's Hospitals.*—Res. Obstet. O. £175. Each at rate of £50.

[illegible] *2, Fitzjohn's-avenue, N.W.*—Pathologist.

[illegible] *Riding Infirmary.*—Third H.S. £125.

[illegible] *ton, S.W.*—Two Res. H.S.'s. Each at rate of [illegible]

Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. or H.S. At rate of £100.

Northampton General Hospital.—H.S. H.S. to Ear, Nose and Throat Dept. Also Cas. O. Each at rate of £150.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Nottingham General Hospital.—H.S. for Ear, Nose, and Throat Dept. At rate of £150.

Plymouth, Prince of Wales's Hospital, Lockyer-street.—H.S. At rate of £150.

Preston, Biddulph Grange Orthopædic Hospital.—Jun. H.S. At rate of £150.

Princess Beatrice Hospital, Richmond-road, Earl's Court, S.W.—H.S. and H.P. Each at rate of £110.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P. At rate of £125.

Princess Louise, Kensington, Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.

Queen Alexandra's Imperial [illegible] *The War Office, Whitehall, S.W.*- [illegible]

Queen Charlotte's Maternity [illegible] *N.W.*—Res. Anæsthetist. A rate of £100. Res. Anæsthetist and Dist. Res. M.O. At rate of £90. Asst. Res. M.O. At rate of £80. Also Obstet. Surgeon to Out-patients, and Fourth M.O. to Antenatal Dept.

Rotherham Hospital.—Cas. H.S. £150.

Royal College of Physicians, Pall Mall East, S.W.—Milroy Lecturer.

Royal National Orthopædic Hospital, Gt. Portland-street, W.—Two H.S.'s (one for Country Branch). Each at rate of £150.

St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C.—H.S. At rate of £75.

St. Thomas's Hospital, S.E.—Surgeon. Also Surgeon to Out-patients.

Salford Royal Hospital.—H.P., two H.S.'s. Also Cas. H.S. Each at rate of £125.

Sheffield Royal Hospital.—Res. Ophth. H.S. Also Res. Asst. Cas. O. At rate of £120 and £80 respectively.

Sheffield Royal Infirmary.—Second Asst. Cas. O. At rate of £80.

Southampton, County Borough.—Deputy M.O.H. £720. Also Asst. Port M.O.H. £500.

[illegible] *Hants and Southampton Hospital.*— [illegible]

[illegible] *Women, Clapham Common, S.W.*— [illegible]

[illegible] st. M.O. £600.

[illegible] I.S. At rate of £140.

[illegible] Villiam Julius Mickle Fellowship. [illegible]

Wakefield, Menston Mental Hospital.—Fifth Asst. M.O. £350.

West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each at rate of £100.

[illegible] *Sanctuary, S.W.*—"Wander" [illegible]

[illegible] *lesden-road, N.W.*—Asst. Surg. O. [illegible]

Wolverhampton Royal Hospital.—H.S. for Fracture and Orthopædic Dept. At rate of £100.

Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—Res. M.O. £175.

Zetland County Council.—M.O. and Public Vaccinator. £80.

Births, Marriages, and Deaths

BIRTHS

COOK.—On August 23rd, at Beaconsfield, the wife of J. A. Lumsden Cook, M.B. Edin., of a son.

CORFE.—On August 23rd, at Welbeck-street, the wife of Felix N. Corfe, M.R.C.S. Eng., L.D.S., of Muswell Hill, of a son.

EVANS.—On August 20th, at Eltham, the wife of J. D. Evans, L.M.S.S.A., of a son.

FORSTER.—On August 19th, in Jerusalem, the wife of E. D. Forster, M.R.C.S. Eng., Hebron, of a son.

MCCONAGHEY.—On August 18th, at a nursing-home, Plymouth, the wife of Richard M. S. McConaghey, M.B. Edin., of a daughter.

PURVIS.—On August 23rd, at Southampton, the wife of Raymond Purvis, M.B. Lond., F.R.C.S. Eng., of a daughter.

WEBB.—On August 26th, 1935, to Josefine, M.B., B.S. Lond., wife of John Robert Douglas Webb, Lieut.-Colonel Indian Medical Service, of Haddon Close, (near) Didcot, Berkshire—a son.

MARRIAGES

O'MEARA—CROFT.—On August 20th, at Warwick, Francis Joseph O'Meara, M.D. Dub., F.R.C.P. Irel., Major, R.A.M.C., to Janet Glendower Croft.

DEATHS

ACTON.—On August 23rd, Lt.-Colonel H. W. Acton, C.I.E., M.R.C.S. Eng., I.M.S., late Director of the School of Tropical Medicine, Calcutta.

BISHOP.—On August 19th, in Guernsey, Henry Draper Bishop, M.D. Brux., M.R.C.S. Eng., for 27 years medical officer of health to the island.

FULLER.—On August 17th, at Tremeer, Perranporth, Andrew Fuller, M.R.C.S. Eng., L.R.C.P. Edin., in his 77th year.

GOWAN.—On August 22nd, at Bournemouth, Bowie Campbell Gowan, M.R.C.S. Eng., L.S.A., aged 83.

HUTCHINSON-LOW.—On August 21st, at a nursing-home, Richard Marsden Hutchinson-Low, O.B.E., M.B. Edin., late of Cromwell-road, Kensington.

WEBSTER.—On August 21st, at Ventnor, I. of W., Henry William Webster, M.D. Brux., M.R.C.S. Eng., aged 91.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

WE deeply regret to record the death of Dr. George H. Morrison, which occurred on August 23rd as a result of injuries received through being knocked down by a motor omnibus. Dr. Morrison, who for the last eight years has been a medical adviser to Bayer Products Ltd., was previous to that a sub-editor on the staff of THE LANCET, and his tragic death will be learned with regret by many of our readers as well as of the staff of the paper.

ADDRESSES AND ORIGINAL ARTICLES

CHRONIC CONSTRICTIVE PERICARDITIS

(PICK'S DISEASE)

TREATED BY PERICARDIAL RESECTION*

By Paul D. White, M.D. Harvard

FROM THE MASSACHUSETTS GENERAL HOSPITAL, BOSTON, MASS.

I BRING to you progress notes of a study of a subject concerning which pioneer but forgotten observations were made by Englishmen years ago, especially by Lower[25] in 1669, by Chevers[9] in 1842, and by Wilks[43] in 1870, but which has received no adequate attention in English medical writings of our own day. This subject concerns congestion that is not due to myocardial failure and in particular that which results from chronic constrictive pericarditis. The teachings of Mackenzie, Lewis, and others of the English school dealing with congestive heart failure have borne rich fruit, but the small though important harvest of the exceptional cases of congestion of other sort has not yet been gathered.

Introduction

Chronic constrictive pericarditis consists of a chronic fibrous or callous thickening of the wall of the pericardial sac which is so contracted that the normal diastolic filling of the heart is prevented. A condition called "inflow stasis" results. There may or may not be calcification of the pericardium, obliteration of the pericardial cavity, or important external pericardial adhesions. There may or may not be an associated accumulation of pericardial fluid in small amount, as in pockets. The parietal pericardium may be preponderantly affected or the epicardium also seriously involved; or both pericardial membranes may be securely or even inseparably united. One section of the pericardium, as over the cardiac apex, may remain relatively free and but slightly thickened, while another part, as over the right auricle and great veins, is markedly contracted; or the entire heart and roots of the great vessels may be encased uniformly in a tightly fitting envelope. There may or may not be an acute or chronic polyserositis, which is, contrary to a common belief, a different thing. There may or may not be frosted liver or spleen. There may or may not be heart disease itself—in my experience the association of chronic constrictive pericarditis, of any important degree at least, with heart disease is very rare; I have encountered only one likely case, and this I believe to be a coincidence.

The signs of chronic constrictive pericarditis are similar in most respects to those of acute constrictive pericarditis, or cardiac tamponade, due to pericardial effusion, and indeed the signs of the former condition may follow the signs of the latter without any interruption at all, or more often after an interval of months or years. The insidious evolution of the disability due to chronic constrictive pericarditis, frequently with no history of a preceding acute pericarditis, makes the diagnosis far more difficult than that of acute constrictive pericarditis that usually develops with striking signs and symptoms in the course of a few hours or days.

In 1896 Pick[30] emphasised the common findings of liver involvement and preponderant ascites, and so the disease has often been called by his name.

The establishment of the diagnosis of chronic constrictive pericarditis has a three-fold importance: (1) it affords the explanation of a group of symptoms and signs in an obscure case; (2) it obviates confusion with other conditions, especially mitral stenosis, cirrhosis of the liver, polyserositis, and nutritional or other rare type of œdema; and (3) expert thoracic surgery may now lead to cure of what was once a hopeless disease.

Historical Résumé

Galen,[18] about A.D. 160, described pericardial effusion in a monkey and scirrhous thickening of the pericardium in a cock and surmised that the same conditions might occur in man and interfere with proper heart function; also he observed post-traumatic septic anterior mediastinitis in a young man on whom he operated successfully, removing some of the diseased sternum, and even the vertex of the pericardium, which he uncovered (the first record of pericardial resection). Although, moreover, the hairy heart had been mentioned now and again in the Middle Ages (and considered a sign of valour), Lower[25] should receive the credit for the first satisfactory account of pericardial disease in man. He may be said also to have initiated the era of recognition of acute and chronic constrictive pericarditis which progressed for about one hundred years. This was in 1669, some years before Bonetus[3] and Vieussens[39] reported cases in 1679 and 1715 respectively. Lower's account is so illuminating that I shall give several quotations from it:—

> "Although the fluid enclosed in the pericardium serves effectively for lubricating the surface of the heart and facilitating its movement, it sometimes happens that a profuse effusion oppresses and inundates the heart. This envelope becomes filled in hydrops of the heart; *the walls of the heart are compressed by the fluid settling everywhere so that they cannot dilate sufficiently to receive blood* (italics mine); *then the pulse becomes exceedingly small, until finally it becomes utterly suppressed by the great inundation of fluid,* whence succeed syncope and death itself. . . . Just as the accumulation of too much water in itself brings harm to the heart so it happens that trouble comes when heart and pericardium become everywhere closely adherent; whence, when it becomes attached also to the diaphragm the motion of the heart necessarily mingles and combines with that of the diaphragm. That there must needs be much impediment and inconvenience to both has been shown above and will be still more apparent from the story that follows."

Lower then cites the history of a London housewife, aged 30, who over a period of three years until her death declined steadily in health, with dyspnœa, precordial discomfort, weakness, and a small and intermittent pulse. At post-mortem examination the only important finding was, complete pericardial adhesion. Lower states that "this membrane was not, as is proper, thin and transparent, but thick, opaque, *and even callous.*"

In 1728 Lancisi[27] made the clinical picture of chronic constrictive pericarditis much clearer by citing the case of a man, aged 24 years, with small pulse and marked swelling of the jugular veins and of the abdomen, who showed at necropsy a small heart with thick completely adherent pericardium.

To complete the first century of the recognition of chronic adhesive pericarditis, Morgagni[29] in 1761 reported seven cases; one of whom, a man 40 years old with a very small pulse, showed a heart "so constricted and confined that it could not receive a proper quantity of blood to pass on." But, he noted that most of the cases were incommoded little or not at all even shortly before death, as was true of a strenuous fisherman. It was this rather abrupt realisation that there may often be an adherent pericardium without any *symptoms* or *signs* therefrom, a point of view emphasised further by Laennec [26] in 1819, that distracted the attention of the medical profession in general from the possible importance of chronic constrictive pericarditis for well over one hundred years; this may be termed the period of neglect. There is little mention of the subject except in passing, if at all, by the leading medical authors of the day, including Corvisart,[12] Kreysig,[24] Laennec,[26] Hope,[22] Williams,[44] Stokes,[36] and Skoda.[35]

---

* The St. Cyres Lecture of the National Hospital for Diseases of the Heart, London, July 10th, 1935. The lecture has been divided into two parts, of which the second (to appear in our next issue) contains all the references.

Then at the very end of the nineteenth century (Pick,[30] 1896) there began a period of enlightenment which has culminated in (1) the clinical recognition of the disease itself, and (2) the successful application of surgery in a considerable proportion of the cases. During the half century, before Pick's work, four physicians made observations of great importance which for some reason or other almost completely escaped notice. Two of these four were Germans, Griesinger [20] and Kussmaul,[25] and they have been accorded more recognition than their two English predecessors, Chevers [9] and Wilks,[43] who were fully aware of the details of the clinical picture. It is of interest that Wilks in 1870 deplored the lack of interest in the subject to which his reading of Chevers (1842) had attracted his attention; while Kussmaul (1873) demanded recognition of the disease which Griesinger (1854) had observed; yet both Wilks and Kussmaul also apparently spoke to deaf ears.

Under the title "Observations on the Diseases of the Orifice and Valves of the Aorta," Chevers [9] cited as one cause of a narrow condition of the aorta the diminution of the heart that may follow the obliteration of the pericardial cavity. Hope had observed "that he had never examined after death a case of complete adhesion of the pericardium without finding enlargement of the heart, generally hypertrophy with dilatation." Chevers in contradiction wrote:

> "With deference to this high authority, I must venture to suggest that the above remarks can be applied only to one class of cases of this description—to those in which, superadded to the adhesion of the pericardium, there is also disease of the valvular passages of the heart; these cases are certainly the most frequent; but I think that a sufficient number of contrary instances have occurred, under my own notice, to prove that, where the valves are healthy, complete and close adhesion of the pericardial surfaces, far from producing hypertrophy and dilatation, has a tendency to be followed by general diminution in the size of the heart and its vessels, and contraction of its cavities."

He noted that in the course of seven years, 1835 to 1842, at Guy's Hospital no case of cardiac enlargement plus chronic obliteration of the pericardial sac failed to show valvular disease or other cause for the enlargement.

His first case report of chronic constrictive pericarditis was that of a girl, 18 years old, admitted to the hospital on June 23rd, 1841, suffering from ascites. About a year and a half previously she had begun to experience difficulty in breathing, and swelling of the legs, and afterwards of the abdomen, which was tapped three times. She died on Sept. 1st and autopsy showed tuberculosis of the right lobe of the cerebellum, miliary tubercles in the lungs, adherent pleuræ, adhesive pericardium, normal heart valves, "nutmeg" liver, congested kidneys, several pints of ascitic fluid, and roughened peritoneum over the liver and spleen, marked by small white depositions. "The cavity of the pericardium was entirely obliterated by a layer of firm and almost cartilaginous deposit, evidently of long standing, and, in some parts, nearly half an inch in thickness. The heart was remarkably small."

Chevers concluded that "the principal cause of dangerous symptoms in cases of the above description appears to arise from the occurrence of gradual contraction in the layer of adhesive matter which has been deposited around the heart, compressing its muscular tissue, and *embarrassing its systolic and diastolic movements, but more particularly the latter.*" (Italics mine.)

In 1870 Wilks [43] wrote: "I do not find, however, in turning to the standard text-books on medicine that mention is made of adherent pericardium, as one of the causes which lead to impairment of the heart's action with the usual accompaniments of venous congestion and dropsy. I may more than others feel surprised at this, since I have known what they may not have been aware of, that the subject had been discussed in the pages of this work thirty years ago." He said that "as a rule the greatest thickening is in front, so as to affect the right auricle and ventricle." The great veins and mediastinum may also be encased. He presented reports of six cases, five males aged 21, 9, 12, 26, and 24 years respectively, and one female aged 16 years.

In 1873 Kussmaul [25] also published an important paper which completed the era of the earliest clinical recognition of this disease. Evidently unaware of the work of Chevers and Wilks, he stated that callous mediastino-pericarditis demanded more attention than was given to it in contrast to the well recognised purulent mediastinal infections and that it had characteristic anatomical and clinical features, especially the involvement of the great vessels, the inspiratory swelling of the neck veins, and the pulsus paradoxus (which he named, but which is better called "marked decrease in pulse amplitude in inspiration—the Griesinger-Kussmaul pulse"—since in slight degree it is a normal phenomenon in the thoracic type of respiration). To his knowledge at that time only one clear-cut case of this condition had been reported, observed by Griesinger [20] in 1854, and described by Widenmann [42] in 1856 under the title "Consideration of the diagnosis of mediastinitis" in a Tübingen inaugural dissertation. The pulse tracing was published by Vierordt [41] in 1855.

With Griesinger's observation in mind Kussmaul in the summer of 1873 made ante mortem the correct diagnosis in two cases of "schwielige (callous) mediastino-pericarditis."

In spite of these four important contributions by Chevers, Griesinger, Wilks, and Kussmaul, and incidental papers by Concato [11] on polyserositis in 1881, by Hutinel [23] on "cardiac and tuberculous cirrhosis of the liver" in childhood in 1894, and by Harris [21] on indurative mediastino-pericarditis in 1895, little interest was shown in chronic constrictive pericarditis until Pick's [30] more familiar contribution at the end of the century. His paper was entitled "Concerning chronic pericarditis running its course under the guise of cirrhosis of the liver (pericarditic pseudocirrhosis of the liver) with observations on the frosted liver (Curschmann)." He reported three cases, all males, of 47, 26, and 24 years of age respectively, and discussed in particular the differential diagnosis between chronic pericarditis and primary cirrhosis of the liver.

Pick recognised the fact that the frosting of the liver was not a necessary part of the condition but rather a complication due to chronic peritonitis. Curschmann [13] in 1884 had labelled this condition "perihepatitis chronica hyperplastica (Zuckergussleber or frosted liver)," and described the case of a woman, 54 years old, who died with acute tuberculous peritonitis superimposed on chronic, which was a part of a polyserositis (pleuritis and pericarditis). Here the liver was small and hard and constricted by a dense chronically inflamed capsule 4 to 5 millimetres thick which surrounded the gall-bladder also. There was no trace of interstitial liver fibrosis or of vascular disease. The heart was apparently normal and not constricted by the adherent pericardium. Thus, this was not a case of Pick's disease. It is of further interest that "frosting" may occur elsewhere than over the liver and spleen, as in a case of frosted intestine without pericarditis reported by Borrmann [4] in 1927.

There are two other important names in the history of the work on chronic constrictive pericarditis before the turn of the century that demand mention, and they are Weill,[41] who in 1895 suggested, and especially Delorme,[14] who from 1895 to 1898 insisted, that relief might be brought to these patients some day by pericardial resection. It was a good many years, however, before this advice was followed.

Türk [37] in 1901 discussed the differential diagnosis of "pericardial concretion" and emphasised three points: first, that along with internal adhesions there may or may not be any important external adhesions with signs thereof, such as systolic retraction of the chest wall; second, that polyserositis or perivisceritis may antedate adhesive pericarditis; and third, that the differentiation from tuberculous peritonitis and from tricuspid and mitral valve disease is more difficult than from true cirrhosis of the liver, in contradistinction to Pick's point of view. He noted that the peritoneum may or may not be involved in these cases. Other workers on pericarditis over this period, like Broadbent and Brauer, were interested primarily not in chronic constrictive pericarditis but rather in external adhesions.

Another interval of time passed and then appeared the two most important recent contributions, namely, the introduction of pericardial resection itself independently by Rehn [31] and by Sauerbruch [32] in 1913, followed by Schmieden [33] in 1918, and the classical paper on the diagnosis of chronic constrictive pericarditis by Volhard [40] in 1923.

Volhard [40] stated that callous thickening and shrinkage of the pericardial sac result in a typical disease picture with effusion in the abdominal and sometimes in the thoracic cavities. That these effusions at times possess an inflammatory character because of attacks of polyserositis can make more difficult the explanation of the disease picture but cannot obscure the predominant influence of the callous pericarditis itself. He said further that the condition was hardly ever recognised, largely, he thought, because reliance was placed on several individual signs which were not pathognomonic. Much more important in his experience was the total picture of the disease with its evolution and "inflow stasis." He wrote that the most important and conclusive indication was the high-grade venous stasis with small heart, overfilling of the neck veins, big liver, and "ascites præcox." He pointed out that in this condition the cardiac difficulty is in the restriction of diastole in contrast to the effect of important external pericardial adhesions which increase the heart load in systole.

In the last ten years there have been a few additional papers worthy of note. In 1926 Fischer [15] amplified Volhard's classical paper on the diagnosis of chronic constrictive pericarditis. He introduced a discussion of the X ray evidence and observed that the heart shadow may be enlarged by the thick pericardium itself, that there may or may not be pericardial calcification, that pericardial calcification may occur without constriction of the heart, and that tuberculosis did not appear to be the ætiological factor in his own series of 8 cases (6 operated on and 2 others autopsied). Fischer also joined Schmieden the same year (1926) in a good review [33] of the subject with anatomical and physiological observations and a discussion of the pathological findings, the diagnosis, and the treatment; they reported 8 operations on 7 cases, one case having had successfully first, a freeing of the anterior surface of the heart over the right chambers, and second, a freeing of the posterior surface over the *left* chambers.

In 1934 Schur [34] of Vienna wrote an extensive review of the subject with a good bibliography.

He pointed out that cardiac systole as well as diastole is interfered with in Pick's disease but to a lesser degree, that the myocardium may also show some damage in these cases, that there may be a "hydrothorax præcox" as well as an "ascites præcox," that inspiratory swelling of the neck veins is a common and important sign (present in 13 of his 17 cases), that internal pericardial adhesions (concretio cordis) and external pericardial adhesions (accretio cordis) are not commonly isolated, both being present in varying degrees in most cases, that the heart may be enlarged (it was enlarged in 12 of his 17 cases), that auricular fibrillation is not uncommon (in 6 of his 17 cases), that there may be various electrocardiographic anomalies (12 of his 17 cases were studied by electrocardiogram—5 showed pronounced and 2 others showed a slight degree of low voltage), and that several of his cases had a rheumatic ætiology, which is not our experience.

Following the German lead, workers in three centres in the United States have taken a special interest in chronic constrictive pericarditis and have assembled important series of cases with operative cures:—

(1) Beck [1] and his associates in Cleveland, Ohio (14 certain cases of chronic constrictive pericarditis, 10 operated upon, 5 cured, 1 improved); (2) Burwell [7] and his associates in Nashville, Tennessee (10 certain cases of chronic constrictive pericarditis, 7 operated upon, 3 greatly relieved and 2 partially relieved); and (3) Churchill and myself [10] at the Massachusetts General Hospital, Boston (15 proved cases of chronic constrictive pericarditis, 12 operated upon, 6 cured, and 1 seventy-five per cent. relieved).

In other countries than Germany and the United States there has been relatively little interest in the diagnosis and operative treatment of this condition of chronic constrictive pericarditis. The lack of an adequate discussion of the diagnosis in the English language has caused me to present herewith this historical review and a survey of our own cases in Boston with their considerable percentage of operative cures.

Our Own Experience

Until seven years ago there was no special interest in chronic constrictive pericarditis at the Massachusetts General Hospital, though one of our own staff [8] had called attention to Pick's paper and had reported an interesting case. Rarely patients in the clinic were diagnosed as having Pick's disease—I can recall two between 1915 and 1925—but as chronically ill cases they excited no particular interest and there was *no relief for them* except for repeated abdominal taps. After the case reported by Richard Cabot in 1898 only two others came to autopsy at the hospital in the next thirty years.

On Jan. 24th, 1898, Richard Cabot,[8] then physician to out-patients at the hospital, related the history and post-mortem examination of a boy of 18 who for six years had suffered from an enlarged liver and for four years from ascites. His past history revealed nothing of importance; measles at the age of seven years had been his only illness. Cabot wrote: "Death occurred (8 weeks after entering the hospital in 1893) apparently from pulmonary œdema and exhaustion. The diagnosis at the time of death was entirely uncertain. The absence of any history of alcohol and of any history or lesions of syphilis, congenital or acquired, made cirrhosis of the liver unlikely. There did not appear to be sufficient evidence of cardiac or renal disease to explain the signs. Tubercular peritonitis seemed unlikely in view of the nature of the fluid obtained by tapping and the absence of nodules or masses in the abdomen after tapping. The sputum was repeatedly examined for tubercle bacilli with negative results. The possibility of a new growth in or near the liver and pressing on the portal radicles or otherwise obstructing the portal circulation could not be excluded, and was considered on the whole the most likely diagnosis.

"*Autopsy* showed the following: Heart of normal size; muscular substance presents nothing abnormal. Pericardium entirely obliterated by firm fibrous adhesions; in the upper part a small, cheesy nodule. Liver greatly enlarged; nutmeg surface on section. Kidneys dark red in colour, with evidence of abundant blood."

In 1925 we were confronted by a new and important patient, a pioneer who for us opened up the rich experience that has followed and who shared with Dr. Churchill the distinction of the first surgical cure of the condition in America.

CASE 1.—Miss C. S., at the age of fifteen years, entered the Massachusetts General Hospital for study on Jan. 26th, 1925. Eight years before she had for two months suffered from smothering spells, fever, a big liver, and fluid in her abdomen. Following this illness she had remained perfectly well for about seven years, that is, until the age of 14, with no cardiovascular signs or symptoms.

In March, 1924, she suffered bilateral peritonsillar infection and "smothering." Her physician again found enlargement of the liver and abdominal fluid, and for the four months before entrance to the hospital she had been in bed. In the past she had had, in addition to the illnesses noted, chicken-pox, whooping-cough, mumps, and influenza (in 1919). She had never had rheumatic fever, chorea, scarlet fever, diphtheria, pleurisy, or pneumonia, and there had been no known exposure to tuberculosis. Her family history was entirely unimportant.

On examination she appeared well developed and nourished, lying flat in bed, in no respiratory distress or pain. The right tonsil was enlarged. The lungs were clear. The heart showed slight enlargement and shifted with change in position. There was no Broadbent's sign. There was a moderately loud systolic murmur at the apex with a third sound. There were no diastolic murmurs. The liver was enlarged, the edge being palpable 6 cm. below the costal margin; it was not pulsating. The blood pressure varied from 130 millimetres mercury systolic and 80 diastolic to 95 systolic and 60 diastolic. The pulse was regular at a rate of 90. During her three weeks in the ward she had one bout of fever, up to 102° F., with a sore throat. Tonsillectomy was carried out on May 4th at the Massachusetts Eye and Ear Infirmary under gas and ether anæsthesia.

X ray examination (Jan. 31st, 1925) showed a definite increase in transverse measurements of the heart shadow, particularly to the left, with well rounded apex, somewhat increased supracardiac shadow, and rather marked increase in prominence of the lung hilus shadows on both sides. The electrocardiogram showed normal rhythm at a rate of 90 with late inversion of the T waves in Lead 1, slight inversion of the T waves in Lead 2, and prominent Q waves with upright T waves in Lead 3. The blood showed very slight anæmia and no leukocytosis. The urine, kidney function, and stools were normal. W.R. negative.

The patient was digitalised without benefit, and discharged on Feb. 17th, 1925, with a diagnosis of "chronic mediastino-pericarditis, chronic tonsillitis, ascites, and perihepatitis."

Because of increase in abdominal fluid and failure to respond to digitalis and diuretin she re-entered the hospital on June 19th, 1925. There were the same findings on examination as before except for an increased amount of ascitic abdominal distension and prominence of the jugular veins. Calomel and novasurol produced slight diuresis only, and finally on July 17th she had an abdominal paracentesis which yielded 4500 c.cm. of clear straw-coloured fluid with a specific gravity of 1·018. On culture this fluid showed no growth and inoculation of a guinea-pig was negative for tuberculosis. She was discharged on July 18th, 1925.

During the next three years she attended the cardiac clinic in the out-patient department regularly, and received digitalis and theocin. The digitalis was discontinued after a while because it in no way affected the ascites. Twice during this interval the abdomen was tapped. She lived a quiet life, unable to resume school.

In 1927 her legs began to swell for the first time, and this symptom increased considerably early in 1928. In April, 1928, she began to have dyspnœa on slight exertion and œdema of the face and upper part of the body; in May, 1928, she had to go to bed, and in June she re-entered the hospital ward following advice that I had given in a pessimistic letter which I had written to her doctor on April 27th, 1928. "She certainly has had a very miserable time and I am afraid there is not much that can be done to help her. There seems little doubt but that pericarditis is at the back of her trouble. Probably she has a good deal of mediastinal involvement and disability of the heart itself. I would suggest resuming digitalis grs. 1½ t.d.s. for a few days and then once daily for a few weeks. If after two or three weeks she is not better I would advise that she come into the hospital again with a thought of considering cardiolysis if there is any chance of freeing the heart. I suppose, however, that the prognosis is poor at best." Dr. E. D. Churchill about this time returned from study abroad which had included observation of pericardial resection in Sauerbruch's clinic. I asked him to see this girl with me, and he agreed to operate. At that time there had been no successful cases in the United States.

The patient and her family consented, and on July 18th, 1928, when she was 18 years old, she submitted to an anterior pericardial resection, which included the removal of a band compressing the inferior vena cava. A very thick pericardium was found constricting the right ventricle and right auricle and great veins. An area the size of the palm of the hand was removed. Microscopically the pericardium that was removed showed a degenerative fibrous connective tissue.

After a moderately stormy two or three days following the operation she began suddenly to improve, and a spontaneous diuresis started on the fifth post-operative day; in the course of a few weeks she lost all her œdema and ascites and her liver decreased considerably in size until the edge could be felt just below the costal border. Her weight dropped from 139½ pounds before the operation to 109 twenty-five days after the operation. Her heart murmur was barely audible.

This patient has been in excellent health and full activity for nearly seven years since her operation (she was last examined on May 16th, 1935). (Figs. 1 and 2.)

The electrocardiogram on April 29th, 1935, showed normal rhythm at a heart-rate of 65, with slightly reduced voltage of the Q R S waves, low T waves in Leads 1 and 2, and slightly inverted T waves in Lead 3; this record shows lower voltage of the Q R S waves than that before the operation, but the T waves are more normal (they were inverted in Leads 1 and 2 in 1928).

With this auspicious beginning seven years ago we have gradually accumulated our experience with 14 more cases of chronic constrictive pericarditis. The account of these patients I have arranged in several groups, beginning with the largest, namely, five others who have been completely cured by operation. Adding these to the first case, we thus have Group A consisting of six patients who illustrate well the features of the cases most amenable to treatment. Then follows one case (Group B) relieved in major part, but not completely cured, by operation. Group C contains three cases who died primarily of the lesion itself; in them the disease was unusually severe and fulminating in its course; in two of these operation probably hastened the end by a few days, while in the third our previous experience warned us of the inoperability of the condition and the patient died without operation. The fourth group (Group D) includes three cases who died of complications, a few days post-operatively in two patients and one year after operation in the third; in two sepsis was responsible (apparently unrelated to the pericardial lesion in one but directly related or superimposed in the other), and in the third true portal cirrhosis of the liver and posterior pericardial adhesions conspired to cause death. Finally, Group E consists of two living cases, older patients, one with a mild and the other with a moderate degree of constriction, not proved by operation but by characteristic signs and X ray evidence of pericardial calcification.

I shall now describe the other five successful cases.

Group A.—CURED CASES

[CASE 1.—Reported above.]

CASE 2.—Mrs. L. F., housewife aged 30, was sent to me on Jan. 9th, 1933 because of obstinate anasarca. She had always been well and active except for scarlet fever as a child, appendicitis with operation four years before, and a quinsy sore-throat three and one-half years before, at which time she was laid up for four or five weeks. Two and one-half years before my examination she began to have œdema of both feet equally, slight dyspnœa on exertion, and some palpitation, but no pain. These signs and symptoms increased gradually until a year before I saw her when the swelling had involved both legs to the hips, and also the abdominal wall and the belly itself. The dyspnœa had increased somewhat but was never prominent. For a year there had been little change in the condition. She was a semi-invalid, and had puzzled several physicians because of the failure of the dropsy to respond to ordinary remedies such as digitalis, mild diuretics, and rest. Her parents, two brothers, and three sisters were living and well. One brother and one sister had died of tuberculosis. Her one child was in good health.

Physical examination showed a slender woman with much œdema of the legs and moderate prominence of the abdomen. There was a visible pulse in the neck veins in the upright position. Her heart was normal in size; sounds good, no murmurs, but a rather loud third sound at the apex. The heart rhythm was normal and the pulse-rate 84. The blood pressure was 105 mm. systolic and 70 diastolic. The pulse was small. The lungs were clear. The diaphragm was high. The abdominal wall was œdematous and both legs showed marked œdema extending up to the hips and waist. X ray examination showed normal size of heart and aorta, with little or no pulsation of the right heart border but active pulsation of the left. The left leaf of the diaphragm was displaced upwards by each heart beat. There was a slight amount of fluid in the right pleural cavity. The electrocardiogram showed normal rhythm, rate 105, with low voltage of the Q R S waves and low T waves in all leads. The T waves in Leads 2 and 3 were slightly diphasic.

She was admitted to the hospital on Feb. 10th, 1933, and her pericardium was resected by Dr. Churchill on April 6th. The pericardium that was removed showed microscopically fibrosis but no tuberculosis. Just before operation the urine, blood, and stools were normal; the Hinton reaction was negative, the basal metabolic rate was plus 5 per cent., and the venous pressure as measured by direct method was 16 cm. The serum protein was reduced to 3·1 per cent. and 4·1 per cent. with albumin 1·5 and globulin 2·6. Following operation the serum protein measured 5 per cent.

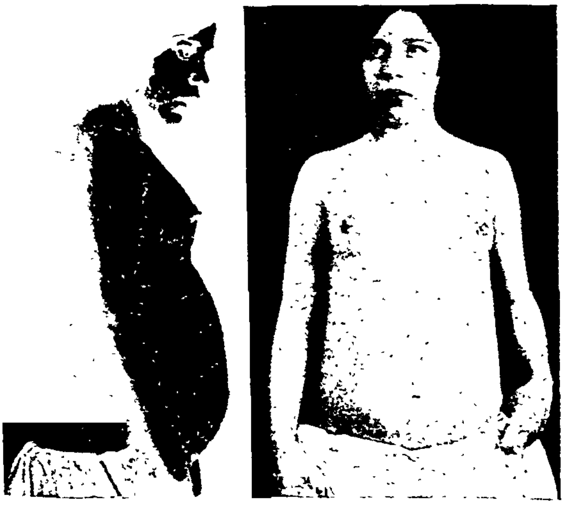

FIG. 1.—(Case 1). The patient, C. S., at the time of her disability from chronic constrictive pericarditis.

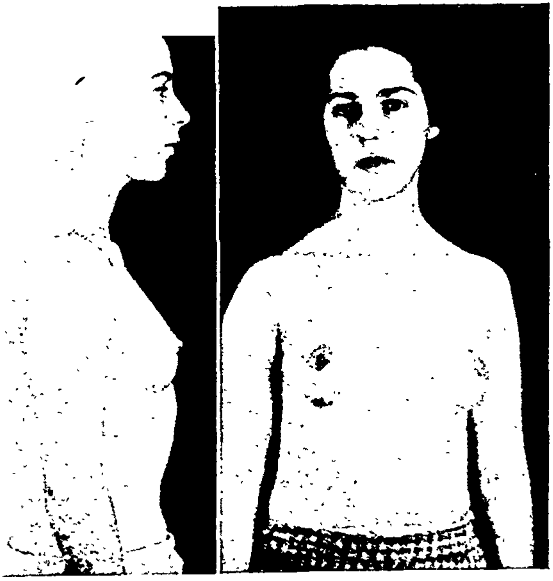

FIG. 2.—Same patient seven years after operation. Her cure, evident in these pictures, was completely effected within a few weeks of the pericardial resection.

After operation she made a rapid recovery with disappearance of symptoms and signs within one month; a spontaneous diuresis began three days after the operation and continued to a loss of 20½ pounds of œdema fluid. Since her discharge she has been in excellent health in the last two years (examined on May 16th, 1935) and has not only resumed the care of her household but has worked in a mill.

The electrocardiogram on May 16th, 1935, showed normal rhythm at a heart-rate of 100, slight right axis deviation, and slightly inverted T waves in Leads 2 and 3; this differs from the record before the operation in that the T waves in Leads 2 and 3 are inverted, and the voltage is somewhat higher, namely, within normal limits.

CASE 3.—C. A. F., male 19 years of age, entered the Massachusetts General Hospital on Feb. 23rd, 1933. Two years before he had to give up track sport at high school because of increasing dyspnœa. Six months later he began to tire very easily and three months after that, he noticed generalised swelling of his face every morning, swelling of his legs at the end of the day, and increase in the size of his abdomen. He had to rest one day a week, but kept at school otherwise. After leaving school he rested entirely for a month and improved somewhat. A recurrence of signs and symptoms caused consultation with a physiotherapist who declared that his heart was bad, and electrical treatments were advised. He improved slightly, but in the fall, six months before admission to hospital, his dyspnœa and œdema increased, and his weight rose from 156 to 164 pounds. A physician prescribed digitalis and a diuretic, and the weight was reduced temporarily. The obstinacy of the dropsy, however, finally caused his entrance to hospital.

In the past he had had chicken-pox, measles, mumps, whooping-cough, and pleurisy with bronchitis, the last named six months before he began to have shortness of breath. The family history was good, the father, mother. and three brothers being alive and well.

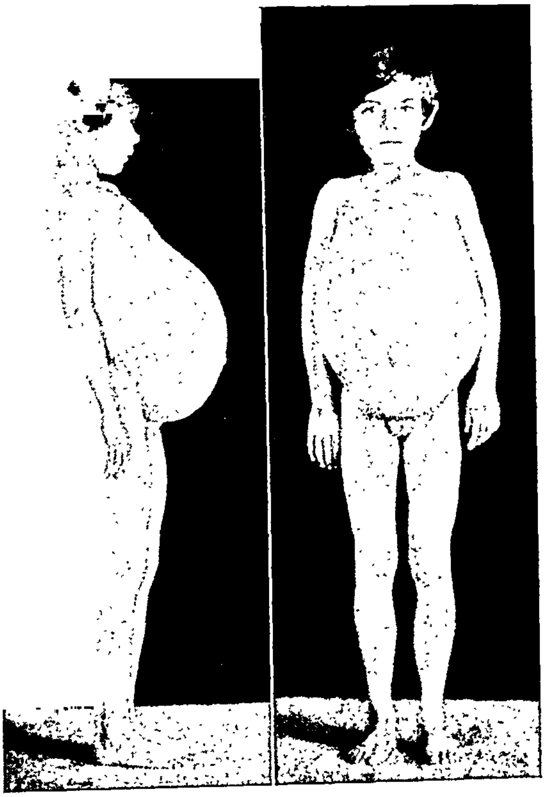

FIG. 3.—(Case 5). B. K., at the time of her disability. Her condition was unchanged for seven years (5 to 12 years of age.)

Physical examination showed a lad in no distress, but with massive pitting œdema of both legs, some œdema of the scrotum, moderate enlargement of the liver, a heart of normal size with distant sounds and no murmurs, a regular pulse of 80, blood pressure of 110 mm. systolic and 60 diastolic, and distension of the neck veins. X ray examination showed normal heart size, thickening of the pleuræ, increase of the supracardiac shadow, and no evidence of pulsation at the right heart border. The lung hilus shadows were slightly increased. The electrocardiogram showed normal rhythm at a rate of 88 with inverted T waves in Leads 1 and 2. Urine and blood were normal. The serum protein was 3·3 per cent., increasing to 4·5 per cent. soon after the operation. The liver function was diminished. The basal metabolic rate was minus 9 per cent.

On April 22nd, 1933, pericardial resection was carried out by Dr. Churchill. A thickened pericardium adherent to the heart was found and removed from the left ventricle, right ventricle, and right auricle. The diaphragmatic pericardium was resected. There was a small pocket of fluid at the diaphragmatic surface. The right auricle in the region of the inferior vena cava was decorticated. On microscopic examination the tissue removed showed fibrosis. There was a slight decrease of œdema on the third post-operative day with the onset of definite diuresis on the sixth day. His œdema and ascites were entirely gone in eighteen days during which time he lost thirty-five pounds of fluid. He has been well in the past two years since the operation (examined May 16th, 1935).

The electrocardiogram taken August 17th, 1934, sixteen months after the operation at which time the patient was well, showed normal rhythm at a heart-rate of 80, with flat T waves in Lead 1, late slight inversion of the T waves in Lead 2 (of the so-called coronary type), and moderate inversion of the T waves in Lead 3; this record shows improvement over that taken before the operation which showed inversion of the T waves in Leads 1 and 2, and lower voltage of the Q R S waves.

CASE 4.—L. C., a lad of 12, entered the Massachusetts General Hospital on June 30th, 1933 with a story of gradually increasing size of his abdomen over a period of three months. He had no other symptoms or signs, and was annoyed at having to interrupt his usual activities to be treated. Four days before admission to this hospital his abdomen had been tapped in another hospital, where calcification of the pericardium had been discovered by X ray.

He had been critically ill with pneumonia at the age of four years, had measles, mumps, and chicken-pox between the ages of four and six years, and a light attack of whooping-cough after that. His tonsils had been removed at the age of two. His father died of tuberculosis (three months before this boy was born). His mother was living and well.

Physical examination showed a well-developed but not well-nourished boy with heart at the upper limit of normal in size, good heart sounds with a loud reduplicated pulmonary second sound, and no murmurs. The blood pressure measured 90 mm. systolic and 60 diastolic. The veins in the neck, arms, and upper chest were dilated. The lungs were clear. The abdomen was somewhat distended (it had been tapped a few days before). The edge of the liver was palpable 6 cm. below the costal margin. There was shifting abdominal dullness but no œdema over the legs or lower back. There was no fever. The blood was normal except for slight secondary anæmia. Urine was normal and stools were normal. The Hinton reaction was negative. The liver function was slightly reduced. The serum protein measured 4·8 per cent. before operation and 6·4 per cent. after operation. X ray examination showed a full-sized heart with increase in the size of the great vessels and enlarged lung hilus shadows, slight thickening of the axillary and apical pleuræ, and a linear area of calcification extending around the entire lower part of the pericardium. The electrocardiogram showed normal rhythm at a rate of 85, with low T waves in Lead 1, diphasic T waves in Lead 2, and inverted T waves in Lead 3.

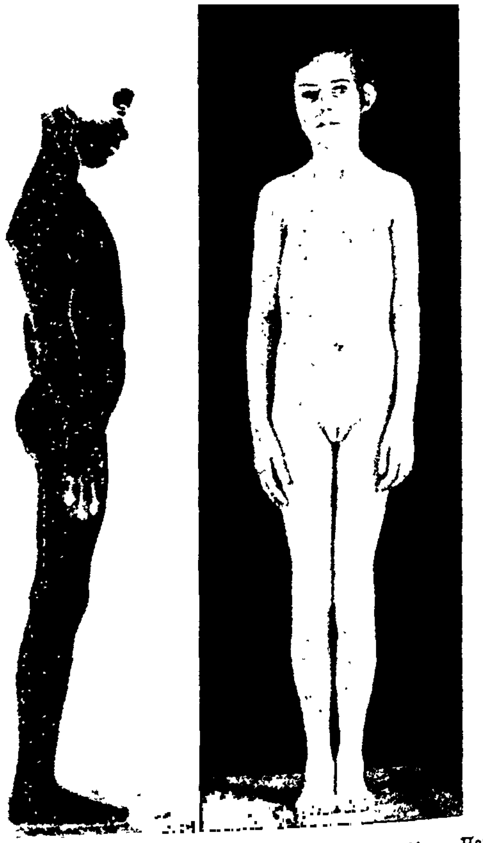

FIG. 4.—Same case one year and a half after operation. Her cure was completely effected within a few months of the pericardial resection.

Pericardial resection was carried out by Dr. Churchill on July 12th, 1933. The fourth, fifth, and sixth costal cartilages were resected as in most of the other cases. A thick hard pericardium with areas of calcification was found and resected from the right ventricle, right auricle, and inferior vena cava. Most of the diaphragmatic pericardium was also resected. The pericardium over the left auricle was not cleared. During the first two post-operative days there were vomiting and acidosis, and then rapid improvement began; spontaneous diuresis appeared on the sixth post-operative day, and continued for twelve days with a loss of eight pounds of fluid, and a shrinking of his girth from 28 to 24½ inches. He has been perfectly well since, during the past two years, and now plays all kinds of games actively, including baseball and football. (Last examination, May 16th, 1935.)

The electrocardiogram, May 16th, 1935, showed normal rhythm at a heart-rate of 70, with normal upright T waves in all leads; this record has now returned to a perfectly normal state in comparison with the record taken before the operation.

CASE 5.—B. K., a girl aged 10, entered the hospital on Oct. 13th, 1931, with a history of having lived a semi-invalid life since the age of 5½ due to a markedly enlarged abdomen resulting from the presence of much ascitic fluid. When she was twenty months old she suffered from what was apparently an attack of acute pericarditis, and her abdomen became enlarged. At the age of 2½ a laparotomy was performed and a gangrenous appendix was removed. No tubercles were seen on the peritoneum at the time of operation. A drain was inserted, and the patient made a good recovery. The fluid returned in about three weeks but following an abdominal tap one month later there was no recurrence of fluid for three years. At the age of 5½ the abdominal fluid returned, and six months later a Talma operation (omentopexy) was done. Abdominal fluid injected into a guinea-pig gave negative results. There was no improvement following this operation, and at the age of 9 the patient entered a second hospital for further study. Her abdomen was tapped at that time, but not again after that until her entrance into the Massachusetts General Hospital in the fall of 1931 when 6240 c.cm. of straw-coloured fluid with a specific gravity of 1·013 were removed.

Her mother had died of tuberculosis during the patient's infancy. Her father is living and well.

Physical examination showed a thin, somewhat pale, young girl with heart apparently normal in size and sounds and without murmurs, and with prominent jugular veins and a large protuberant, non-tender abdomen, filled with fluid. X ray examination showed heart and great vessels somewhat displaced to the right and anchored to the diaphragm; no pulsation was evident at the right border of the heart and great vessel shadow; the right pleura was thickened.

The electrocardiogram showed normal rhythm, rate 100, with inverted T waves in Lead 2.

Advice was given at that time that the chest be explored surgically and the adhesions constricting the right auricle, right ventricle, and great veins be freed.

After an interval of two years this girl returned to the hospital in an unchanged condition with persistence of the enlargement of the abdomen. The serum protein measured 4·3 per cent. X ray and electrocardiographic findings were as before.

Pericardial resection was carried out on Nov. 16th, 1933, and a moderately thickened pericardium containing calcareous plaques was removed from over the right ventricle and right auricle by Dr. Churchill. The pericardial tissue that was removed showed fibrosis and calcification on examination. There was a stormy time for two days after the operation, and during the first two weeks there was no apparent improvement. About four weeks after the operation spontaneous diuresis began and in the course of a few months the ascites completely disappeared. She has been in excellent health since, and looked well when she was last examined by us on May 16th, 1935. (Figs. 3 and 4.)

The electrocardiogram on May 16th, 1935, showed normal rhythm at a heart-rate of 80, with slightly upright T waves in Lead 1, flat T waves in Lead 2, and very slightly inverted T waves in Lead 3; this record differed from that taken before the operation in that the T waves were more normal and the voltage of the Q R S waves was greater.

CASE 6.—D. G., a schoolgirl aged 11, entered the Massachusetts General Hospital on Dec. 31st, 1934, with a history of fatigue and apathy during the previous year, and abdominal swelling for eight months. Two months after the abdominal swelling began heart trouble was diagnosed and medicine, apparently digitalis, was given. The ascites, however, persisted and occasionally puffiness of the eyelids in the morning was noted. She had been in bed most of the time for three months.

On examination she was a well-developed and rather poorly nourished girl, sitting quietly in bed, with no apparent pain or distress. She was very cheerful. The skin and mucous membranes were somewhat pale. The heart was normal in size. The sounds were good, with no murmurs, but a loud third sound at the apex. The pulse-rate was regular at 90. There was very slight elevation of temperature, 99½° to 100° F. rectal. The blood pressure was 98 mm. systolic and 70 diastolic. There was moderate distension with pulsation of the veins in the neck. The venous pressure was 21 cm. in the jugular vein. The lungs were clear. The abdomen was rounded, firm, but not tender, with shifting dullness in the flanks, and a definite fluid wave. The liver edge was palpable 5 to 7 cm. below the costal margin. The spleen was not felt. There was no œdema of the legs. There was a slight "paradoxical" pulse. The Hinton and tuberculin tests were negative. The liver function test was slightly reduced. The blood was normal except for slight secondary anæmia. The urine was normal and the stool was normal. The serum protein was 7·4 per cent. Two litres of straw-coloured fluid were removed from the abdomen by tapping. The specific gravity of this fluid was 1·016. Injected into a guinea-pig it gave no evidence of tuberculosis ten weeks later. X ray examination showed normal heart size and shape with good pulsations. There was no evidence of fixation of the heart or of adhesions. There was some increase in the shadow of the great vessels at the base to the right of the midline, with increase in the lung hilus shadows. The electrocardiogram showed normal rhythm with inverted T waves in Leads 2 and 3.

Pericardial resection was advised, and she was readmitted to hospital later, on Feb. 4th, 1935. Pericardial resection was carried out on Feb. 27th. A thick, but not calcified, pericardium, adherent to the heart throughout, was discovered and resected from the right ventricle and right auricle. Examination of the pericardium which was removed showed fibrosis without evidence of tuberculosis. She went through an uneventful convalescence except for slight right pulmonary collapse. Spontaneous diuresis began mildly on the third day, but she showed very little improvement prior to her discharge on March 30th, 1935. Since that time she has shown steady improvement at home, and to-day is in good health except that she tires easily. Her abdominal swelling has entirely disappeared.

The electrocardiogram on May 16th, 1935, showed normal rhythm at a heart-rate of 120, with slight right axis deviation, slight inversion of the T waves in Lead 2, and moderate inversion of the T waves in Lead 3, much the same as in the record before the operation.

The five cases detailed above were completely cured by operation. The next case, though not so successful, was greatly relieved by operation.

Group B.—GREATLY RELIEVED BY OPERATION

CASE 7.—J. N., aged 16, was referred to us with the diagnosis of chronic constrictive pericarditis. In early childhood he had had chicken-pox and measles; at 5 years of age a tonsillectomy was done. At 9 he had double pneumonia, and was in bed for six weeks. There was a complication of left pleural effusion and this was tapped. Cardiac enlargement and a systolic murmur were discovered then. At the age of 13 routine examination showed some cardiac enlargement with systolic murmur, pulsating veins in the neck, and enlargement of the liver, the edge of which was felt three fingers-breadth below the costal border.

When 14, during the winter of 1929–30, he noticed that his face was swollen and that he had some difficulty in getting on his waistcoat due to enlargement of the abdomen. Œdema of the thighs was developing at that time, and the liver enlarged until its lower edge reached the umbilicus. He continued at school for part time for a year and then had to give up and was living a semi-invalid life when we saw him. He had had very little dyspnœa. Diuretics were used with temporary benefit. Two months before entrance to our hospital his abdomen had been tapped and eight litres of fluid removed. Digitalis had been ineffective. There was nothing abnormal in the family history.

Physical examination showed a well-developed and moderately well-nourished young man, lying comfortably in bed, without dyspnœa, but with slight to moderate engorgement and pulsation in the jugular veins. The pulse-rate was absolutely irregular at a rate of 120, and the pulse was definitely "paradoxical." The blood pressure was 110 mm. systolic and 95 diastolic. The heart showed moderate enlargement. The sounds were of fair quality. There was a loud blowing systolic murmur at the apex; there were no diastolic murmurs. A slight third sound was heard at the apex. The lungs were clear. The abdomen was uniformly prominent. There was slight œdema over the anterior abdominal wall and over the shins. The heart shifted definitely on change in position of the thorax. The liver edge was not tender; it was easily felt, extending across the abdomen half way between the umbilicus and costal border. There were no Broadbent's sign and no clubbing of the fingers or pyrexia. The blood was normal. The urine showed the slightest possible trace of albumin with a rather high specific gravity due to his restriction of fluid intake. X ray examination showed definite enlargement of the heart in all diameters, particularly in the region of the auricles. There was increase in the supracardiac shadow, thought to be due to venous congestion. Barium in the œsophagus showed deviation to the right in the region of the left auricle. Pulsations were weak but definite. The lung hilus shadows were increased, the pleuræ markedly thickened on both sides. Electrocardiogram showed auricular fibrillation at a ventricular rate of 80 with slight right axis deviation, and inverted T waves in Leads 2 and 3.

Pericardial resection was advised, and on Sept. 27th, 1932, this was done by Dr. Churchill. A very much thickened pericardium with some calcium deposit was found and dissected off from the right ventricle and right auricle, and in part from over the left border of the great vessels. A considerable portion of diaphragmatic pericardium extending backward to the region of the inferior vena cava was removed. A considerable amount of calcified pericardium was left, but the amount that was excised allowed the heart to herniate outwards and evidently greatly increased its diastolic filling. Microscopic examination of the pericardium which was removed showed hyaline degeneration of fibrous connective tissue with focal deposits of lime salts.

His post-operative condition was satisfactory but improvement was slow. In the course of the first week the anasarca seemed to be clearing somewhat, and the cervical veins were less engorged. The venous pressure dropped from 28 cm. to 14 cm. After disappointingly slow progress and the use of salyrgan intravenously on several occasions and abdominal paracentesis he returned to his home in Oklahoma where he remained ten months. He returned to us in September, 1933, showing great improvement, but not cured. He had lost about twenty pounds in weight, but still required an occasional abdominal paracentesis. The serum protein was 4·3 per cent. The liver function showed a retention of 10 to 15 per cent. of the dye. His electrocardiogram showed auricular fibrillation with slightly low voltage and slight right axis deviation as before. X ray examination showed some calcification which had not been definitely evident before. It was thought that further pericardial resection was indicated.

On Nov. 16th, 1933, Dr. Churchill operated again with ease through the original scar, which was excised. Calcified pericardium at the base of the great vessels was removed, and the right auricle was more completely freed. The left auricular appendage was dissected free. The pericardial tissue removed showed, as before, fibrosis with calcification. There was an uneventful convalescence after this second operation but no further improvement, and on March 30th, 1934, a Talma operation (omentopexy) was done because of the opinion that the liver condition was now possibly responsible for the persistently recurring ascites. At the time of his operation a small bit of liver was removed, and was found to show only slight "cardiac" fibrosis. The liver capsule was not thickened (no "frosting" or Zuckergussleber).

There has been no distinct improvement following this operation. Frequent abdominal taps were necessary every one to two weeks until a diet very low in both salt and fluid was carried out under careful control during the past spring. On this diet which is somewhat similar to that used by the famous Finsen,[16] who had Pick's disease, there had been no gain in weight and the ascites had been so controlled that an interval of more than six weeks passed from the last paracentesis to the date of my last examination of this patient on May 31st, 1935, at which time he appeared in a fair state of health, quite active, but very dry with considerable weakness (probably from near heat prostration) on hot days—he is unable to perspire because of the marked limitation of fluid and of salt ingested (180 c.cm. of the former and 2·5 g. of the latter each twenty-four hours).

There are various indications that in the case of this young man the remaining disability results from constriction of the left chambers of the heart, especially the auriculoventricular ring, which acts much as mitral stenosis would act. The round shape and moderate cardiac enlargement by X ray examination, the presence of auricular fibrillation with right axis deviation by electrocardiogram, the X ray picture of posterior pericardial calcification, and the knowledge that the anterior surface of the heart is well freed from constricting pericardium are evidence in favour of this point of view. A further operation to clear the pericardial adhesions from the posterior wall of the heart would seem reasonable. Because of his marked improvement in certain respects, however, it has been thought wise, first, to complete a careful study as to the effect of low salt and fluid intake. In Germany a similar case has been successfully operated upon twice,[32] first, with the freeing of the anterior surface of the heart, and second, with the freeing of the posterior surface of the heart. His condition was excellent some years later.

Group C.—CASES WHO DIED PRIMARILY OF THE LESION ITSELF

In two of these (Cases 8 and 9) operation probably hastened the end by a few days; the third (Case 10) died without operation.

CASE 8.—J. M., male aged 36, mechanic, consulted his company physician on Sept. 15th, 1933, complaining of fever, slight cough, and profuse sweating which had come on acutely. His temperature was 101·5° F. The next day he felt a tightness over the lower part of the sternum. X ray examination showed an enlarged heart shadow and a provisional diagnosis of pericardial effusion was made. There was no story of rheumatic fever. He entered the local hospital and remained there three months with an oscillating temperature. A right chest tap brought fluid. He was discharged home from the hospital in December, 1933, where he remained on very restricted activity for six or seven weeks, but then he began to develop abdominal enlargement and œdema of the lower legs. He returned to the hospital on Jan. 18th, 1934. A persistence of his œdema and ascites caused his transfer to the Massachusetts General Hospital for consideration of pericardial resection for constrictive pericarditis. There was no important illness in his past history. His family history was excellent.

Physical examination on Feb. 15th, 1934, showed a very ill man with little dyspnœa but cyanosis of the lips and cold cyanotic extremities. The heart dullness was slightly increased as determined by percussion, and there was no shift on change of position. There was no visible or palpable cardiac impulse. The heart action was rapid (104), regular, with muffled sounds at the apex. There were no murmurs. The pulses were small, and faded out markedly during inspiration (a high degress of "paradoxical" pulse). The blood pressure was 106 systolic and 90 diastolic. There was evidence of right hydrothorax. The abdomen was enlarged with a considerable amount of fluid, and the liver was enlarged and tender, the edge being felt about half-way between the costal border and the umbilicus. There was no œdema of the legs while in bed. He remained under observation in the hospital from Feb. 15th until April 2nd, when he was transferred to the surgical side for operation. During this interval of six weeks there was slight fever, usually about 100° F. rectal in the evening, rarely reaching 101.° An abdominal paracentesis was done four times; the first time 5728 c.cm. of greenish-yellow fluid were obtained, the second time 5376 c.cm., the third time 1536 c.cm., the fourth time 6144 c.cm. The specific gravity of the fluid ranged from 1·010 to 1·012. The urine showed slight albuminuria. The blood showed slight leukocytosis. The blood-serum protein varied from 7·4 to 4·96. The Hinton reaction was negative. The liver function test showed 4 per cent. of the dye retained. X ray examination showed a heart shadow area somewhat greater than normal, with especial increase in the region of the great vessels, more on the right. The borders of the heart were irregular. The pulsations were weak. There was evidence of some fluid in both pleural cavities. His condition was essentially unchanged during his six weeks in the hospital, and on April 2nd, 1934, an attempt was made to decorticate the heart. The electrocardiogram showed normal rhythm, and low voltage with flat T waves in Lead I. and inverted T waves in Leads II. and III.

An extensively thickened pericardium was exposed overlying the heart which was barely pulsating; a part of it was resected. His condition became critical at the beginning of the operation and he died while still under the influence of the anæsthetic. There was no autopsy.

Examination of the pericardium that was removed showed a thickness of 1 cm. Between the surfaces, on which there were tubercles, there was a large mass of irregular friable soft yellowish fibrinous material.

CASE 9.—J. B., male aged 23, a labourer. Previously in excellent health, he began to notice easy fatiguability and weakness in the summer of 1930. These symptoms were sufficient to cause him to change his work from that of a mover to that of an errand boy. In the fall of 1930 he began to notice generalised œdema, first in his neck (his collars became too tight), then in his waist (his trousers became too tight), and soon all over, including his extremities and face. In November, 1930, he had to stop work entirely because of the generalised swelling and increasing dyspnœa and weakness. Shortly after this he had a head cold, and entered a local hospital. There the swelling largely abated, but on his return home recurred to a high degree and continued until his entrance into the Massachusetts General Hospital for study on Jan. 5th, 1931. Other symptoms were a dry and unproductive cough and hoarseness which had developed in the fortnight before admission.

Physical examination on Jan. 5th showed extensive anasarca involving face, neck, trunk, and legs. There were extensive cyanosis and marked dyspnœa and orthopnœa, with hoarse voice. The throat and tonsils were œdematous. The heart showed slight increase in percussion dullness, both to the right and to the left. The heart sounds were distant and poorly heard. There were no murmurs. There was a high degree of "paradoxical" character to the pulse. The blood pressure was 120 systolic and 100 diastolic. The pulse-rate was 90 to 100, and the rhythm was regular. There was emphysematous breathing, and sibilant râles were heard in both lungs. The abdomen was tense, and there was a marked fluid wave. On six successive days paracentesis was performed, first of the abdomen on Jan. 5th when a small amount of yellow, turbid fluid with a specific gravity of 1·022 was obtained. On Jan. 6th his pericardium was tapped and 105 c.cm. of fluid was withdrawn. There was a slightly turbid character to this fluid, and the specific gravity was 1·024. On Jan. 7th his chest was tapped on the right side, but no fluid was obtained. On Jan. 8th the abdomen was tapped again with the same result as on the 5th. On Jan. 9th the pericardium was tapped again and 95 c.cm. of cloudy yellow fluid were obtained, which later gave a positive test for tubercle bacilli after inoculation in a guinea-pig. On Jan. 10th the abdomen was tapped and 100 c.cm. of cloudy fluid, negative for tuberculosis by guinea-pig test, were removed. Finally, on Jan. 13th the chest was tapped once more and 900 c.cm. of bright yellow fluid were withdrawn. The urine showed no abnormalities. The blood examination was also normal. The sputum showed no tubercle bacilli. The Hinton reaction was negative. The venous blood pressure was 32 c.cm. on Jan. 14th.

Because of the seriousness of his illness and the failure to obtain relief by any medical measures, pericardial resection was decided upon, and on Jan. 14th, 1931, this was done by Dr. Churchill.

When the surface of the pericardium was exposed no pulsation of the heart was evident. The pericardium was much thickened (5 mm.), and when incised there was an escape of about 130 c.cm. of thin straw-coloured fluid under pressure. The inner aspect of the pericardium was covered with tubercles. The heart was small, and in no place in contact with or adherent to the parietal pericardium. An oval window approximately 3 in. in diameter was removed from the anterior surface of the parietal pericardium and a V-shaped line of resection was continued on to the diaphragmatic pericardium. The inflammatory process apparently extended around the roots of the great vessels. The heart did not dilate, either due to persistence of constriction of the venæ cavæ or to thickened epicardium.

The patient died with little or no change in his condition on Jan. 15th. There was no autopsy.

CASE 10.—Mrs. A. G., housewife aged 31, began to be troubled in the summer of 1933, by paroxysms of tachycardia, lasting from one to six hours each, associated with fatigue which had followed the birth of her son five months before. Two months after the paroxysmal tachycardia began she consulted her physician who found no abnormalities except for a slight increase in cardiac percussion dullness and a pericardial friction rub. Shortly after this a slight fever was discovered and she was sent to bed. Two weeks later she developed an unproductive cough. The fever and friction rub persisted, and she was admitted to a hospital near her home, and remained there for three months. Blood culture and Wassermann reactions were negative. There was a slight secondary anæmia. She improved somewhat and was sent home. The pericardial friction rub had finally disappeared after persisting for several weeks.

On Jan. 15th, 1934, she began to be breathless and cyanotic and on examination showed marked jugular engorgement, enlarged liver, and ascites. She was readmitted to the hospital on Feb. 1st, and fluid was found on both pleural cavities which were tapped. The pleural fluid showed a specific gravity of 1·020. The tapping on one occasion was followed by a severe attack of pulmonary œdema. On March 8th peritoneal fluid was withdrawn, showing a specific gravity of 1·020. She was discharged home in April, 1934, after having had a favourable diuresis from the use of salyrgan. During the spring and summer of 1934 she was in a rather poor state of health with gradually increasing weight due to increase in the degree of dropsy. Abdominal paracentesis was carried out twice. Salyrgan was injected once or twice a week with varying response, and Southey tubes were inserted early in October. She had been in bed most of the time with increasing dyspnœa as well as œdema.

She was admitted to the Massachusetts General Hospital on Oct. 18th, 1934, for consideration of pericardial resection. At that time she was quite ill, breathing rapidly and shallowly, with marked distension of the neck veins. The heart was little if at all enlarged, without murmurs, but with an accentuated pulmonary second sound. The rhythm was regular. The pulse was small and markedly "paradoxical." The blood pressure was 95 mm. systolic and 70 diastolic. There was evidence of fluid in both pleural cavities and there was marked ascites with great enlargement of the liver, the edge of which was felt, slightly tender, midway between the costal border and the umbilicus. There was œdema of the legs and lower back. Her urine showed very slight albumin, but no sugar or bile. The blood showed very slight secondary anæmia and a white count ranging from 9400 to 12,700.

The abdominal fluid gave a specific gravity of 1·012. Guinea-pig inoculation was negative for tuberculosis. The chest fluid was heavily blood-tinged. On one occasion when 2000 c.cm. were removed from the left pleural cavity there was severe collapse with pulmonary œdema.

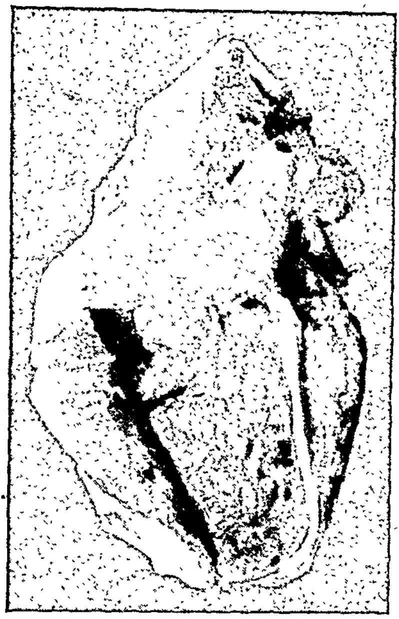

FIG. 5.—(Case 10). Heart and pericardium, showing very thick callous pericardial sac completely encasing the heart.

X ray examination showed the lower two-thirds of the heart shadow obscured by fluid in the pleural cavities, more on the left than on the right. There was no evidence of cardiac pulsation; the heart area seemed somewhat increased. The electrocardiogram showed sino-auricular tachycardia at a rate of 110 with slight left axis deviation, flat T waves in all leads, and slightly prolonged P–R interval, 0·22 second. An effort was made by paracentesis and the use of salyrgan and other measures to get her into condition for operation, but this effort was unsuccessful, and she died Nov. 15th, 1934.

Autopsy showed a markedly thickened and toughened cartilaginous pericardium, 3 to 5 mm. thick, everywhere closely adherent to the heart. A line of cleavage split off the thicker constricting parietal pericardium, but underneath the heart was still closely encased in fibrous epicardium. (See Fig. 5.) The œsophagus was involved, and the trachea also, in dense fibrous tissue continuous with the pericardium. The bronchial glands were surrounded by tough fibrous tissue. The diaphragm was adherent but not itself involved. The orifices of the great arteries and veins were not constricted. The heart itself was normal, weighing 250 g., without any disease of myocardium, valves, or coronary arteries. The aorta, pulmonary artery, and venæ cavæ were normal. The lungs were nearly collapsed and intensely congested. There was no evidence of pneumonia or tuberculosis. Each pleural cavity contained 1 litre of thin, pale yellow, slightly cloudy fluid. There was no pleuritis of any moment; there were a few thin fibrous threads. The peritoneal cavity contained about 1 litre of slightly turbid fluid, but the peritoneum was not involved. The liver showed some cirrhosis, and weighed 1500 g. The capsule was not thickened. The spleen was normal. The kidneys were congested.

We believe that this case would have been curable had we taken her on a few months earlier.

(*To be concluded*)

ILFORD MATERNITY HOME.—As many as 95 cases had to be turned away from this home last year because of lack of room. Fees ranged from £5 5*s*. to 10*s*. a week, and 474 women were admitted with only one maternal death.

OBSERVATIONS ON ANÆMIA IN THE CHRONIC RHEUMATIC DISEASES

By DOUGLAS H. COLLINS, M.D. Liverp.

RHEUMATISM RESEARCH FELLOW OF THE UNIVERSITY OF LEEDS AT THE ROYAL BATH HOSPITAL, HARROGATE

THE frequency with which sufferers from chronic rheumatism present the appearance of anæmia is a commonplace with clinical observers. Llewellyn Jones in 1909 [1] reviewed the results of early laboratory observations and expressed surprise that the blood changes found were so inconstant. Twenty years later, Pemberton [2] writes that "the tendency to anæmia is very definite in the 'infectious' varieties of arthritis" and suggests the importance of the condition of the blood in influencing the metabolic processes in the affected extremities. Pemberton also notes [2 3] that improvement in the arthritis, including relief from pain, often coincides with improvement in the hæmoglobin and red cell content of the blood.

Anæmia, as a symptom or as a complication of the rheumatic diseases, is important. I have repeatedly observed that anæmic patients suffer more from their disabilities than those whose blood condition is normal or nearly so. Such patients complain more of pain, general lassitude, and muscular weakness, and successful treatment of the anæmic state, even though it may be merely "symptomatic treatment," is a definite step in the alleviation of their sufferings. Unfortunately the usual methods of therapeutic attack upon secondary or "chlorotic" anæmias frequently fail in these cases. Thus of 12 patients with chronic rheumatism and a severe or moderate anæmia who were given massive doses of iron, and observed for periods up to 21 days, seven totally failed to respond and only two showed any marked improvement.

The efficiency of various therapeutic measures is at the present time being investigated. The purpose of the present paper is to record the results of certain investigations into the frequency and the nature of anæmia in rheumatic subjects, and the factors which influence its development. Kahlmeter [4] mentions that achylia is probably of no importance in the production of this anæmia; this has been reinvestigated in view of the occurrence of achlorhydria in hypochromic anæmia, as shown by Witts [5] and others. Attention has also been paid to the possibility of dietary deficiencies influencing the blood picture.

TECHNIQUE

One hundred and ninety-six in-patients of the Harrogate Royal Bath Hospital formed the subjects of this investigation. Full examination of the blood has been made on 110 patients and gastric analyses in 100 cases. Hæmoglobin has been estimated on a Sahli-Hellige hæmoglobinometer with accurate coloured glass standards; the method is probably as accurate as any other of equal simplicity. The results are recorded, for comparison with other methods, as grammes of hæmoglobin per 100 c.cm. of blood. Blood was taken from the lobe of the ear of patients three hours after a meal and never immediately after measures of physical therapy. Gastric analysis was made by means of the fractional test-meal. The meal of oatmeal was administered after withdrawal of the resting-juice and after washing out the stomach with water.

INCIDENCE OF HÆMOGLOBIN DEFICIENCY

The hæmoglobin content of the blood was determined in 124 patients (62 male and 62 female). No selection of cases was made and these cases constituted the total number of in-patients of the hospital at a certain time. It was hoped that this small number of cases would constitute a fair sample of the rheumatic population, but it differs from the far larger sample dealt with in the Ministry of Health 1924 Report,[6] in that there is a higher proportion of arthritis and especially of atrophic (infective or rheumatoid) arthritis, which constitutes 41·9 per cent. of our cases. The results of this preliminary investigation are shown in Table I. :—

TABLE I

Hæmoglobin Content of the Blood in 124 Unselected Rheumatic Subjects

—	Hæmoglobin, grammes per 100 c.cm.							
	16–17	15–16	14–15	13–14	12–13	11–12	10–11	<10
Male	6	4	16	16	16	3	1	–
Female ..	–	3	11	21	17	4	4	2
Total ..	6	7	27	37	33	7	5	2

If we accept 14 g. Hb. per cent. as the lower limit of normality, we find that 58 per cent. of the men and 77·5 per cent. of the women have hæmoglobin below this level, and 6·5 per cent. of the men and 16·2 per cent. of the women have a moderate or severe hæmoglobin deficiency (below 12 g. per cent.). This incidence of hæmoglobin deficiency is rather greater than Pemberton and Peirce [7] found to be the case among 700 army and civilian patients: an occurrence possibly explained by the higher proportion of arthritis and of severe cases in my series.

RED CELL COUNT, COLOUR-INDEX, ETC.

The red cell count in rheumatic patients is much less affected than the hæmoglobin. In no case was a hyperchromic anæmia (colour-index more than unity) encountered, and in only 24 out of 75 females and 2 out of 25 males was the total red cell count below 5,000,000. The colour-index of 100 cases varied between 0·96 and 0·49. Nucleated red cells were not met with, and reticulocytes averaged 0·5 to 1·5 per cent. of the red blood-cells. The fragility of the red corpuscles was found to be normal in six cases so examined.

ANÆMIA AND THE TYPE OF RHEUMATIC DISEASE

In order to determine whether anæmia is commoner in any particular type of chronic rheumatism, 170 cases have been classified (Table II.) according to diagnosis and the hæmoglobin content of the blood. Careful consideration has been given to the diagnosis of each case, and cases of doubtful diagnosis have not been included in this Table. The diagnostic classification adopted is given below; it follows, in the main, the more recent classifications of the American and English schools.

Group A. Atrophic arthritis of unknown ætiology, including (1) typical "rheumatoid" polyarthritis. (2) "Rheumatoid" or "infective" arthritis affecting one or more large joints. (3) Ankylosing spondylitis—Marie-Strümpell type.

Group B. Osteo- (hypertrophic or "degenerative") *arthritis.*

Group C. Non-articular rheumatism, including fibrositis, muscular rheumatism, and sciatica.

Two important points are confirmed in this Table. (*a*) Anæmia is far more common among female than among male patients, six times as many females as males having hæmoglobin below 12 g. per cent. This finding may, of course, be due in part to the lower hæmoglobin content and red cell count of the blood in normal women. (*b*) The severer grades of anæmia occur (with an incidence of pathological significance) only in the atrophic arthritis group.

TABLE II

Hæmoglobin Content of the Blood in 170 Cases of Chronic Rheumatic Disease

Hæmoglobin grammes per 100 c.cm.	Atrophic (rheumatoid) arthritis.			Osteo-arthritis.			Non-articular rheumatism.		
	M	F	M + F and p.c.	M	F	M + F and p.c.	M	F	M + F and p.c.
16–17 ..	1	–	1 (1·1)	3	–	3 (13·0)	1	–	1 (1·8)
15–16 ..	–	–	–	2	1	3 (13·0)	3	3	6 (11·0)
14–15 ..	8	8	16 (17·4)	1	4	5 (21·8)	10	6	16 (29·1)
13–14 ..	5	19	24 (26·1)	3	4	7 (30·4)	6	7	13 (23·6)
12–13 ..	7	20	27 (29·3)	3	1	4 (17·4)	7	9	16 (29·1)
11–12 ..	2	10	12 (13·0)	–	–	–	1	1	2 (3·6)
10–11 ..	1	9	10 (10·9)	–	–	–	–	1	1 (1·8)

TABLE III

Males.	Total number of cases with—							
	No free HCl.		Hypochlorhydria.		Normal.		Hyperchlorhydria.	
	M.	F.	M.	F.	M.	F.	M.	F.
(*a*) Atrophic arthritis ..	3	23	–	5	11	23	2	2
(*b*) Osteo-arthritis ..	–	–	–	1	3	5	1	1
(*c*) Non-articular rheumatism ..	–	1	–	1	4	12	1	1

M = male. F = female.

GASTRIC ANACIDITY AND ANÆMIA

Analysis of the gastric contents by the fractional test-meal was performed on 100 cases (Table III.), on which, also, full blood examinations were made. Histamine injections were not given, but the stomach was washed out with water after the withdrawal of the resting juice.

The high incidence of anacidity among the female cases of Group A led me to investigate the influence of this upon the blood picture, and I found anæmia to be most frequent and most severe in this particular group.

It is clear from the figures in Table IV. that achylia is not a constant feature in the anæmia accompanying atrophic arthritis, and that severe anæmia may develop in this disease even in the presence of a normal acid gastric secretion.

CLINICAL SIGNS; HISTORY; DIET

A pallid or sallow complexion is common among arthritic patients, and is not always an index of the state of the blood. It is surprising how often the blood picture will be found normal, or nearly so, in such cases. Definite glossitis was present in only two anæmic patients. Painful and brittle fingernails, a common accompaniment of idiopathic hypochromic anæmia [8] is also commonly met with in atrophic (rheumatoid) arthritis, and cannot be accepted as evidence of a primary anæmic state.

TABLE IV

Hæmoglobin Content and Colour-Index in relation to Gastric Function in 53 Female Cases of Atrophic Arthritis

(Figures are total numbers of cases)

Fractional test-meal.	Hæmoglobin, grammes per cent.							
	15–16	14–15	13–14	12–13	11–12	10–11	9–10	9
Achlorhydria	–	2	10	5	5	1	–	–

—	Colour-index (100 % Hb.=15·57 grammes per cent.).							
	0·90 or more	0·85 to 0·89	0·80 to 0·84	0·75 to 0·79	0·70 to 0·74	0·65 to 0·69	0·60 to 0·64	Less than 0·60
Achlorhydria	1	6	8	5	3	–	–	–
Hypochlorhydria ..	–	–	3	1	–	–	1	–
Normal ..	3	7	4	3	3	–	2	1
Hyperchlorhydria ..	1	1	–	–	–	–	–	–

The age of the patient has no influence on the anæmia. It would appear, however, that the duration of the disease is a factor in increasing the degree of anæmia. Two cases of polyarthritis, one male and one female, were admitted to the hospital within a few months of the onset of the disease and, at that time, showed a blood hæmoglobin of 94 and 90 per cent. respectively. Two and a half years later the disease was still active and the hæmoglobin had fallen to 70 in the male and 56 in the female. There was nothing in the histories to suggest a cause, other than the arthritic process, for this anæmia. It is the view of most authorities, and I agree with this, that the anæmia is secondary to the arthritis, and does not usually precede its onset.

For many years it has been customary for sufferers from rheumatic complaints to restrict or modify their diet. Many of our patients have, therefore, been asked in detail about their diet, but in only two cases with severe anæmia might this have been due to dietary deficiency. It is interesting to note that these two cases were two of the three patients with non-articular rheumatism and less than 12 g. per cent. hæmoglobin, and that both eventually responded to simple iron therapy. In both, meat had been excluded from the diet and green vegetables had been restricted for some years.

CONCLUSIONS

1. Anæmia, due to a diminished hæmoglobin content of the blood with a relatively insignificant fall in the red cell count, is common among patients with chronic rheumatic conditions.

2. Such an anæmia is far more common amongst female patients.

3. The severer degrees of anæmia are practically only encountered in cases of atrophic (rheumatoid or "infective") arthritis.

4. Although anacidity was frequently found among female patients with atrophic arthritis, deficient gastric secretion is not a constant factor in the production of anæmia in these cases. Anæmia of equal severity is encountered in cases with normal fractional test-meal curves, as in cases with deficient acid secretion.

5. There is no specific anæmia accompanying the chronic rheumatic conditions. The anæmia is a simple hypochromic anæmia secondary to the disease process.

SIMPLE ULCER OF THE LARGE BOWEL

By R. A. KERR, M.C., M.B. Belf., F.R.C.S. Eng.

SENIOR ASSISTANT SURGEON, NATIONAL TEMPERANCE HOSPITAL

ABOUT fifty cases of simple ulcer of the colon or other parts of the large bowel have been described by various writers, and some of them—e.g., Quénu and Duval, Soupault, Levy, and Barron—have added to reports of patients whom they themselves had observed an analysis of collected cases. From these accounts it is clear that the cases present themselves in two chief groups, the majority with symptoms of perforation into the peritoneal cavity, the minority with no perforation. The perforating ulcer either develops acutely (like the P.G.U. of hospital conversation) or progresses more slowly to abscess formation. The non-perforating ulcer produces symptoms and signs often not unlike those of neoplasm of the large bowel, for which indeed it has been mistaken. I propose to illustrate these groups with an account of one proved case of non-perforating ulcer and briefer mention of two probable cases of the perforating type, all personally observed. The condition has been defined by Quénu and Duval (quoted by Soupault) as "une groupe des lésions ulcéreuses ne relevant de l'action d'aucun microbe specifique, ni de l'action locale d'aucun agent chimique, et qui ne sont pas secondaire à une lésion initiale (ulcération audessus d'un rétrécissement, ulcérations du tumeurs)." In these days of advancing biochemistry the term "agent chimique" may be found too sweeping; presumably the authors meant it to apply to such chemical bodies as acids, alkalis, metals and their salts which have a caustic action.

Non-Perforating Ulcer

A single woman of 37 years had suffered for years from pains in the sacral region and all over the abdomen. During the past few months these were worse in the right lower quadrant. At the age of 18 years she had "ulceration of the stomach," and from time to time there were recurrent attacks of similar pain.

DIAGNOSIS

On March 18th, 1925, her pain began to be more severe than usual. It was felt around the waist at first and then tended to settle in the right lower abdomen though felt generally. It was described as sharp in character above and griping in the lower abdomen. Vomiting did not occur. The bowels were usually constipated, but there was an action on the day of onset of present trouble and pain had followed. Some frequency of micturition was reported. Her doctor noted a swelling in the right abdomen, and I was asked to see her on March 18th.

At my first examination, the patient moved freely in bed and did not appear to be very ill. The temperature was 100° F.; the pulse varied between 100 and 108, being of fair volume and tension. The tongue was slightly furred and moist, and no abnormality was noted in the throat or chest. The skin of the abdomen was pigmented from the frequent application of hot-water bottles. The wall moved readily on respiration but became resistant upon palpation. A tender swelling about the size of a hen's egg was made out in the line of the ascending colon, and it appeared to me to be fixed, though the patient's doctor had noted its mobility. There was a mobile retroverted uterus with cervical discharge but no other pelvic abnormality. The urine was normal on routine examination.

The patient was removed to hospital with a provisional diagnosis of appendicitis and an enema was given followed by considerable relief. The swelling, though unaltered in size, became less tender and more mobile. The temperature fell to 97° F. and the pulse-rate to 80. A barium enema was found to pass readily to a point just proximal to the hepatic flexure. A barium meal showed narrowing at the site of the swelling. A white cell count gave the following result: total 11,200; polymorphs. 69 per cent., eosinophils 1 per cent., lymphocytes 24 per cent., and large mononuclears 6 per cent. The swelling became smaller, apparently because of release of bowel contents since bowel action was fairly good. The diagnosis was, revised to that of carcinoma of the ascending colon and operation was advised.

THE OPERATION

On March 25th the abdomen was opened under gas, oxygen, and spinal (stovaine) anæsthesia. General examination having revealed no other lesion, ablation of the cæcum, ascending colon, and hepatic flexure was carried out for what appeared to be a carcinoma of the ascending colon. It was noted that the "growth" involved the inner aspect of the bowel only, and did not completely encircle it. The surface was irregular and pinkish-yellow in colour. There was little or no involvement of the lymph glands of the area. No special difficulty was met with except in the separation of the mass from the second part of the duodenum. An anastomosis between the ileum and the proximal transverse colon was made and the peritoneum adjusted over the bare area. The abdominal wall was closed in layers. After a very stormy convalescence, the patient eventually made a good recovery. During the first year following the operation she suffered occasionally from colicky pain. She has reported to me from time to time up to the present with indefinite indigestion, vague "rheumatic" pains in the body generally, such as had often been felt before the operation, and painful breasts. There is still a tendency to constipation.

PATHOLOGY

The specimen was examined after hardening in formalin. Two irregularly rounded ulcers were seen side by side on the medial wall of the colon separated by a strip of intact mucosa. The diameter of each was rather less than ½ in. The edges were sharply defined, steep, and not nodular. The base was smooth and its external surface (i.e., that away from the lumen) was irregular. Section of the ulcer showed an outline closely resembling that of a chronic ulcer of the stomach. There was a thick deposit of yellowish tissue forming the base, which thinned gradually in a centrifugal direction.

Microscopic examination showed at the edge of the ulcer an abrupt loss of the epithelium, which was infolded toward the base. The cell nuclei of the surface epithelium and mucous glands close to the edge did *not* stain well. There was much infiltration of the mucosa and submucous layer with round cells. The muscularis mucosæ disappeared close to the edge and the muscle coat was thickly infiltrated with round cells and broken up toward the ulcer. Everywhere close to the ulcer margin, polymorphonuclear and plasma cells were plentiful. In the muscular coat, a considerable number of vessels were undergoing obliterative endarteritis but the majority appeared to be quite healthy. Several had a surrounding cloud of round cells. The base of the ulcer was formed of granulation tissue, very thickly infiltrated with round cells but with relatively fewer polymorphonuclear and plasma cells.

Perforating Ulcers

(1) ACUTE TYPE

A woman 50 years, married twice (in spite of congenital absence of the uterus), suffered from colicky pain in the lower abdomen for three days. The bowel acted after castor-oil with relief to the pain, but there was a recurrence in a day or so, and the character of the pain changed. It was now severe, constant and referred to the epigastrium. More castor oil was followed by vomiting as well as purging, and the bowel acted daily afterwards though the usual habit was costive. The pain persisted and was especially bad during defæcation.

Ten days after the onset, she was admitted to hospital on the advice of my friend and colleague, Mr. James McClure. The temperature was 99·4° F. The pulse-rate 126. The patient, a stout woman, breathed with difficulty and showed obvious signs of bronchitis. The abdomen was distended, especially in left iliac fossa and left flank, and the wall was rigid. No defined mass was palpable. There was great tenderness. The external genitalia were well formed and pelvic examination confirmed the absence of the uterus. There was much tenderness in the pelvis.

The abdomen was opened by a left paramedian incision and a large quantity of purulent fluid came away from the pelvis. The appendix was merely injected externally. Coils of small intestine were matted together at the lower end of the pelvic colon and some thickening was felt in the mesentery of the latter, but no definite perforation was made out. The abdomen was closed, drainage being provided by a large rubber tube into the pelvis.

Death took place in a few days with no improvement, and a limited post-mortem examination disclosed a perforation in the lower end of the pelvic colon at first into the mesentery and then into the peritoneal cavity. The internal genitalia were apparently absent.

No microscopic examination of the affected part was made. There may be some doubt as to a single perforated diverticulum being the explanation. No other diverticula were noted and they are usually multiple.

(2) SLOWLY PERFORATING TYPE

A woman 73 years, was admitted to hospital on May 19th, 1929. On May 17th she began to suffer from pain generalised around the abdomen, settling later in the right side, where it remained. It was described as a constant dull ache, made worse by walking. There were loss of appetite, headache, and malaise, and on day of onset nausea and vomiting. The vomit was undigested food. The bowels, which usually acted only with medicine, had opened on 19th and no blood or slime had been noticed. Micturition was normal. There was slight cough with some spit.

The patient was pale. Her temperature was 100·4° F., pulse-rate 96. The tongue was dry and slightly furred. No abnormality was noted in the chest or in the nervous system. The urine was normal. A bulging was seen in the right lower abdomen, which moved well on respiration. There was slight general distension but no rigidity was made out. There was a tender fixed mass about 2½ in. by 1½ in. inside the anterior superior iliac spine, extending upwards into right loin. It was irregular in outline. No abnormality was made out in the pelvis. The urine was normal on routine examination. There was a past history of "influenza and inflammation of the bladder" three months previous to present illness. Since then there had been slight pain in the right side of the abdomen and more constipation than usual.

Upon a diagnosis of appendix abscess, a muscle-splitting incision was made over the most prominent part of the swelling and about three ounces of brownish foul-smelling pus evacuated. There was a necrotic patch on the antero-external wall of the ascending colon with a perforation in the centre. The appendices epiploicæ adjoining were swollen and œdematous. *The appendix was not anywhere visible in the abscess wall.* The perforation was infolded with catgut sutures and the abdominal wall closed around a rubber drain.

A fæcal fistula developed after several days and slowly closed. An abscess in the left parotid gland was evacuated on May 24th. The patient was discharged from hospital on July 21st. She has reported from time to time since, having developed a ventral hernia in the scar. Apart from the hernia, which is not easily controlled by a belt, the patient has since enjoyed fairly good health for her age.

There is in this case the natural doubt about the appendix having been the cause of the abscess and the operation having taken place at a time when it was about to burst into the ascending colon. A careful though not exhaustive search was made for the appendix which was not seen or felt in the abscess wall. No stercolith was discovered. There has been no sign of appendicitis since. I am, surgically speaking, reasonably satisfied that the case was one of ulcer, wanting though it may have been in the pathological or legal standard of proof.

Comment

The symptomatology is sufficiently illustrated in the above accounts. In none of the reported cases has a correct preoperative diagnosis been made. In the perforating type, the symptoms are usually ascribed to appendicitis, perforation of ulcer of the duodenum or stomach, or to diverticulitis. It may be very difficult even at operation or post-mortem examination definitely to exclude the last. There are often no symptoms previous to the acute onset of grave illness caused by the perforation, though in the abscess cases the evolution is slower. Sometimes recurrent attacks of colicky pain and abdominal distension with constipation occur and the attacks pass off with diarrhœa; perforation then takes place in a more severe attack than usual.

In the non-perforating type there is often a palpable and mobile swelling, which is diagnosed as a growth of the bowel. In Landqvist's case, however, no swelling was palpable, and in such appendicitis will probably be the favoured diagnosis with right-sided symptoms and diverticulitis with left. It is to be noted that palpable mobile swellings have usually been detected on the right side. In Mintz's case, the ulcer was situated at the apex of an intussusception of rather chronic course, which was the immediate indication for operation.

At operation, the perforating ulcer discloses itself by signs similar to those seen in *perforating ulcers* of the duodenum or stomach. The non-perforating is recognised by an area of induration and injection, covered with lymph or perhaps tending to necrosis, with a depressed centre corresponding to the ulcer crater. On the other hand it may closely resemble a carcinoma of the bowel wall, especially where there is a considerable deposit of fibrous tissue. This was the condition in Morel and Seycheron's case and in my own. In both, however, closer examination revealed that only a portion of the circumference of the wall was involved, and it is unusual at operation to find a carcinoma thus limited. The simple ulcer is often rounded, but if oval tends to spread transversely across the bowel.

Simple ulcer affects males more than females and is commonest between 40–50 years of age. It occurs chiefly in the cæcum and ascending colon, and in the pelvic colon, though any part of the large bowel including the rectum may be affected. Its size varies up to the diameter of a five shilling piece. Various suggestions have been made as to its ætiology, which has been given as inflammatory, bacterial, neurogenic or trophic, digestive or peptic, mechanical, and circulatory (from arterio-sclerosis, thrombosis, or embolus). The one common point in the great majority of the patients is habitual constipation. This, if sufficiently bad, might give rise to an ulcer mechanically by trauma, the persistence and spread being helped by bacterial action from the prolific intestinal flora. If the digestive juices survive the ileocæcal valve, there would be ample opportunity in the constipated person for their action in an acid medium in the cæcum—and the discharge from a cæcostomy in those cases where I have tested it with litmus paper has been acid. It is difficult to fit in the neurogenic or trophic factor. It may apply to the "visceroptotic" patient, but many of the subjects of simple ulcer are not of this type. In Landqvist's case there was thrombosis in the veins at the base of the ulcer; in Morel and Seycheron's and in my own, endarteritis obliterans was noted in several small vessels. The endarteritis has seemed to me to be secondary to the progress of the ulceration, and not to initiate or precede it, though Quénu and Duval express the opposite view. At present it would seem that no one ætiological view can be proved—or disproved.

The prognosis is not good, as might be expected in a condition where the usual manifestation is soiling of the peritoneum from the cæcal or sigmoid cesspool. The post-operative mortality has been as high as 50 per cent.

Surgical treatment has varied from drainage of the peritoneum, stitching and local excision of the ulcer up to extensive ablation of the bowel. It has depended upon the degree of accuracy of diagnosis at operation and the state of the peritoneum. The ideal treatment in the non-perforated case would be excision of the ulcer or of the ulcer bearing segment of the bowel with repair and proximal provision for gas escape. Closure of the opening and drainage of the peritoneum are necessities in the perforated type. Determination of the procedure to be adopted should be founded on the "safety first" principle, based upon a consideration of the local findings and the patient's general condition.

It is a pleasant duty to acknowledge my indebtedness to Dr. H. H. Sanguinetti, who was responsible for the pathological examination in Case 1, and to Mr. James McClure, assisted by whose advice I operated upon Case 2.

OBSERVATIONS ON CHOREA

THE ENVIRONMENTAL FACTOR

By G. F. Walker, M.D. Leeds, M.R.C.P. Lond.

HON. PHYSICIAN, SUNDERLAND ROYAL INFIRMARY, SUNDERLAND CHILDREN'S HOSPITAL, AND DARLINGTON MEMORIAL HOSPITAL; CONSULTING PHYSICIAN, SUNDERLAND MUNICIPAL HOSPITAL

Late last summer I found myself in possession of clinical notes of over 200 cases of chorea, personally observed in hospital or private practice. I was greatly depressed by the severity and chronicity of this disease and by our ignorance of its cause and cure. When I began to reflect upon its incidence several generalisations became clear:—

1. Chorea has always been common in Sunderland, but it is quite rare in the airy uplands to the south and west of the town. And it is distinctly rare in the lovely grassy valleys to the south and west of Darlington.
2. There appears to be a definite relationship between population-density and chorea.
3. Chorea is quite uncommon in Children's Homes and similar institutions where sound wholesome food, regular meals, and punctual hours of sleep prevail.

I have been able to trace 188 patients and make complete inquiries, on a formal plan, respecting medical and social states, diet, housing, environment, temperament, and a good many similar matters. The children for the most part were typical specimens of what Vining[1] calls the "debilitated child," but most of them were pleasant and gentle. All except 7 came from lowly homes. Boys numbered 62 and girls 126, and the age-incidence rose steeply to a maximum at eight years, afterwards falling slowly, with a small secondary peak about puberty. The onset of chorea was maximal in December and January and minimal in July, August, and September.

My inquiries into the present state of the patients gave the following results:—

Dead from endocarditis	3
Found to have organic heart disease	21
Subject to a single recurrence of chorea ..	28
Subject to several recurrences	17
Subject to residual restlessness	16
Total	85

Many others were found to be in indifferent health of one sort or another, to which irrelevant factors contributed.

CAUSATION

I agree with other writers that there is no physical criterion of a liability to chorea; but the following information bearing on causation was obtained.

Previous definite and considerable disease of the tonsils	29
Excessive carbohydrate in the diet	39
Provocative illness, such as scarlet fever ..	10
Imitation, alleged on good grounds	1
Family history of chorea	6

There is one ætiological factor which I cannot reduce to statistical form; but from discussions with the parents and from domiciliary visits made by my helpers I am sure it should be emphasised. That factor is a lack of fresh milk in the child's diet. I came to this conclusion before I was aware of the work of Stephens,[2] Warner,[3] and Mutch[4] on calcium deficiency in this disease. Another highly important factor is previous prolonged general poor health and catarrh.

As regards social environment the following facts may be noted. In 60 cases the patient came from a family in which there were six or more children. In 19 cases one parent was dead or otherwise missing, and in a further 23 one parent was odd, eccentric, or invalid in some way. Damp and draughts were conspicuous in the homes of 40 children, and in 44 cases reports of serious noise were sifted and checked, e.g.—

"In the tenement flat above are 10 children."
"Neighbours very noisy all night. Much fighting."
"Neighbours upstairs hold prayer-meetings every night."
"Very noisy street swarming with children."
"House very noisy until 1 A.M."
"Lives over a wireless shop."

In 31 cases serious and astonishing overcrowding was found, e.g.—

"Six persons living in one room with two beds."
"Three rooms, all below street level."
"One lavatory for 30 persons."
"Family of 9, four rooms; dark, damp, and verminous."
"Two rooms for family of 9. Lying low near the river."
"One lavatory and one tap for 25 persons."

In 65 cases the patient came from a family living seriously below the level of subsistence when food, rent, and transport are taken into account. Here is a selection of family budgets:—

No. in family.	Total income.	Rent.	No. in family.	Total income.	Rent.
6	34/–	8/3	7	30/–	6/–
4	35/6	11/6	6	32/–	6/–
8	37/3	13/10	6	32/–	6/9
6	37/–	4/9	5	42/–	8/6
4	35/–	6/–	8	45/–	12/6
3	18/–	4/6	4	22/6	8/3
6	34/–	13/–			

Emotional factors were investigated, but the figures probably are low because all information was rejected if it could not be checked independently.

Serious and prolonged deprivation of sleep ..	37
Exposure to a premature religiosity	9
Exposure to inordinate affection	19
Exposure to notorious and prolonged family jars	6
Personal and peculiar anxiety or fear	10

There are other emotional factors of which I feel convinced but which I cannot present in statistics. Thus I believe that chorea is apt to occur in a child upon whom family and domestic responsibilities are prematurely thrust.

For one cause or another the patients of this review were long victims of generally lowered bodily health and obvious debility, anorexia, and catarrh. As a rule the parents could not attribute the onset of the disease to any single event; but a few records were secured, as follows, in which the onset seemed to bear a close relationship to particular events or stresses.

(*a*) Physical injury on trauma .. .. (e.g., scald, lacerated scalp, injuries in a fire, severe caning at school, and dog-bite.)	26
(*b*) Emotional strain .. .. (e.g., excitement of getting work as a maid, fright in the swimming baths (3 cases), "too much education" (3 cases), scholarship attempts (2 cases), suddenly startled by noise, and aroused out of sleep-walking.)	16

These figures are very much smaller than I would have expected.

CLINICAL SIGNS AND TREATMENT

I am aware of sundry classifications of chorea but I venture to suggest a further description of the types as follows: (1) "Always fidgeting." (2) "Makes faces." (3) "Keeps dropping things." (4) "Gone off her feet." (5) "Won't talk." (6) "Keeps wriggling about." (7) "Right bad with her nerves."

The only treatment I found effective was quiet and rest in hospital with competent sympathetic nursing. I am no believer in treating choreic children by stern seclusion behind screens. On the contrary I am quite sure that these patients sigh and pine for a good deal of attention. Chorea makes a child touchy and unstable, and the illness may be prolonged if she feels she is in any way of less importance than the others in the ward.

My patients were almost uniformly obedient, passive and quietly content in hospital. They appeared to have good appetites but were prone to constipation. I think severe cases recovered more quickly than mild cases but this is an impression which I have not been able to confirm.

I am much indebted to Miss W. H. Redmond, formerly house physician in the Sunderland Children's Hospital, and also to Miss McPherson, lady almoner, for valuable help.

Clinical and Laboratory Notes

BLACKWATER FEVER IN A NEGRO CHILD

BY CLEMENT C. CHESTERMAN, O.B.E., M.D., M.R.C.P. Lond.

OF THE BAPTIST MISSION HOSPITAL, YAKUSU, BELGIAN CONGO

IN a hyperendemic malarial region such as the Central Congo Forest native children either die of malignant malaria or gradually reach the condition called *prémunition* by Edmond Sergent—more generally known as "tolerance" by English malariologists. This progressively acquired freedom from febrile attacks, although parasites are still present in the blood and are frequently reinoculated by mosquitoes, goes hand in hand with an immunity from blackwater fever.

That natives from non-malarial regions are subject to severe fevers and blackwater when removed to endemic zones is well known, but among those who have acquired tolerance from childhood non-susceptibility to blackwater fever has until lately been regarded as almost absolute. Recent evidence has shown, however, that under certain conditions this protection may break down, and the following case with which I can find no parallel in my experience or in available records is an instance of this breakdown.

The patient was a boy, aged 2½, of full-blooded negro stock. For first eighteen months of life he attended the infant welfare clinic at Yakusu Hospital, and received the routine weekly dose of 0·04 to 0·10 gramme of quinine hydrochloride in solution. He had further quinine intermittently during and after this time when feverish.

Attack of hæmoglobinuria.—After two days' fever at his village he was brought to hospital on Feb. 5th, 1935, and was given a dose of 0·08 g. of quinine. Next day he passed normal urine at 6 A.M. and went with his mother to the market, where the passage of dark red urine was noticed. The parents had the sense to collect about 75 c.cm. in a tin and bring it to hospital. The child's condition was good: the temperature was 37·5° C. and the spleen three fingers-breadth below the costal margin. The urine was dark red and acid, and contained 0·7 per cent. of albumin; the deposit showed very scanty red cells and numerous granular and epithelial casts. Chemical tests for hæmoglobin positive. The blood showed malarial pigment in monocytes but no parasites.

Treatment and progress.—Copious drinks of 2½ per cent. solution of sodium bicarbonate were given. The next passage of urine was practically normal and next morning only a trace of albumin was left. On the third day a similar dose of 0·08 g. of quinine was given without untoward results. A week later scanty schizonts of *Plasmodium falciparum* were found in the blood. Two months later the child was well, the spleen now being only one fingers-breadth below the costal margin.

It is difficult to escape the conclusion that in this case hæmoglobinuria was definitely precipitated by the dose of quinine, given during a febrile period, to a child whose tolerance to malaria had been retarded by frequent quinine medication. *P. falciparum* and *P. malariæ* are the commonest parasites, *P. vivax* and *P. ovale* also occur in this region. The splenic index in the neighbourhood is 100 at the age of 2–3. Infant mortality is computed at about 500 per 1000, and is mainly due to pneumonia or diarrhœa complicating the frequent malarial attacks of the first two years. Intense infection with *P. falciparum* is often responsible for sudden death.

Mortality among the clinic babies is less than 150 per 1000 and we attribute this result mainly to the assistance of the regular weekly (occasionally more frequent) dose of quinine, which helps them to tide over the dangers attending the acquisition of tolerance. In the last ten years over 1000 babies have attended the clinic and this is the only case in which hæmoglobinuria has been observed. The disease is of course unknown to local inhabitants.

From the Katanga copper mining areas Leclef[1] and de Decker[2] have reported 28 cases of blackwater fever with 3 deaths among natives whom they state came from regions where malaria is endemic. Leclef attributed his cases to the unaccustomed dose of 1 to 2 g. of quinine, and in de Decker's 17 cases quinine had been given to his knowledge in all but 4 before the onset of the blackwater. He considers however that liability to blackwater was due to the predisposing causes of debility among bush natives working in industrial conditions.

There seems to be little doubt therefore that, both in adults and children of the negro race, the irregular use of quinine, especially in moderate or large doses during a febrile period, can precipitate hæmoglobinuria, just as it does among Europeans and Asiatics. There is no indication however that the generally accepted opinion as to the value of regular prophylactic quinine in assisting the acquisition of tolerance to malaria should be modified. That it may retard it, both among blacks and whites living in bush conditions in endemic areas, is quite possible. But the attendant dangers of pernicious attacks and later of blackwater fever are much diminished by its use.

ANURIA TREATED WITH SPINAL ANÆSTHESIA

BY D. S. HAYES, M.R.C.S. Eng.

LATE RESIDENT MEDICAL OFFICER, HOSPITAL ST. CROSS, RUGBY; AND

R. H. PARAMORE, F.R.C.S. Eng.

HON. GYNÆCOLOGICAL SURGEON TO THE HOSPITAL

IN the following case a young man had signs of intestinal obstruction after appendicectomy and subsequently developed anuria. The latter was relieved by spinal anæsthesia, and the case is reported because it may throw light on anuria occurring in other conditions—e.g., after labour or prostatectomy.

A well-made young farmer of 25, after his third attack of appendicitis, had his appendix removed on May 29th, 1932. Battle's incision was chosen, and the operation was difficult. The cæcum could not be delivered, and the base of the appendix was displayed only after enlarging the wound. The appendix passed over the brim into the pelvis, to the wall of which it was adherent: it ended in an indurated mass, thought to be an enlarged gland, with which it was removed. A rubber tube was inserted and the wound closed. The distal mass consisted of coils of the appendix; and from a raw area present it seemed that the tip had been left behind.

---

[1] Leclef: Ann. Soc. belge de méd. trop., 1931, xi., 293.

[2] de Decker: Ibid., 1932, xii., 213.

The next day (May 30th) the abdomen was fuller than expected, and there was a good deal of hæmorrhagic discharge from the wound. On the 31st the abdomen was distended and tender; vomiting occurred; enemata were ineffective. The drainage-tube was replaced by a larger one under spinal anæsthesia; it was hoped this would relieve the abdominal distension, but an enema given later produced little result. On June 1st the bowels were well opened, but the abdomen remained distended, though the vomiting had stopped. The hæmorrhagic discharge from the wound increased; chlorine dressings were applied; there was no suppuration.

On June 2nd the wound was irrigated with dilute chlorine solution, and the irrigation was repeated several times—possibly under pressure, which had not been desired. In any case the condition of the abdomen got worse, and on June 4th it was explored medianly. The small intestines in the lower abdomen were found matted together and covered with a thin layer of blood; there was no adhesion to the parietal peritoneum. Douglas's pouch was cleaned out, necrotic material being removed. No attempt was made to unravel the agglutinated intestines; a large drainage-tube was inserted and the wound closed. On the 6th both tubes—the median and the lateral—were removed, reliance being placed on fomentations, radiant heat, and general nursing.

During the next ten days the patient passed through a critical time. The abdomen was very distended and tense, vomiting frequent, and enemata of little effect. The distension became so great that the wounds began to give way and coils of intestine appeared at both of them; thick pus was now freely discharging from the lateral wound, where the cæcum came to view. As a result of treatment the vomiting diminished, fæces and flatus were passed in small quantities, and the abdominal distension gradually became less, but not uniformly. The prominence of the lower right quadrant of the abdomen proved on palpation to be an indefinite mass, consisting of dilated and adherent small intestines. On June 15th the patient was so improved that a little solid food was allowed. The next day an injection of pituitrin followed by an enema produced a good fæcal result. On the 20th the abdomen was flaccid except in the right ilio-umbilical region, where the prominence persisted. The urine was free of albumin and slightly acid; it had a specific gravity of 1014.

Improvement continued slowly, pain and distension recurring occasionally. On July 12th the patient was allowed out in a spinal carriage. The same evening he vomited and complained of abdominal pain, but passed a good night. On the 13th abdominal pain persisted all day, getting gradually worse (4 P.M.). He vomited twice. Twelve ounces of urine were passed in the morning, difficulty and frequency of micturition appeared, and from 2 P.M. to 8 P.M. only one ounce of urine was passed. Heat was applied to the abdomen without advantage. At 8 P.M. the temperature was 100° F.; the patient was very restless and looked ill. Pain, flatulence, and vomiting prevented sleep until 2.45 A.M., though atropine gr. 1/100 and omnopon 0·5 c.cm. had been given at 11 P.M. Up to 8 A.M. no urine had been passed.

During the morning (July 14th) vomiting of green material persisted, but in the afternoon the patient slept. Heat to the body continued. At 6 P.M. the temperature was 101°; an enema without result. One ounce of urine was passed during the day, and on boiling it became solid. At 10 P.M. the blood pressure was 145 systolic, 105 diastolic. Spinal anæsthesia was induced, 1·9 c.cm. of tropacocaine being injected after some cerebro-spinal fluid had dribbled away. Sims's position, foot of bed on blocks. Fluid intake limited to three pints per 24 hours. At 2.45 A.M. a castor oil and turpentine enema, followed by a simple one, caused a good deal of flatus to pass. At 3 A.M. abdominal pain still present; atropine and omnopon repeated.

At 8 A.M. the next day (July 15th) the patient's condition appeared slightly improved; but the anuria persisting, the spinal anæsthesia was repeated (9.15 A.M.). The result was magical. At noon two ounces of urine were passed, containing much albumin (Esbach, 4·75), and at 3.30 P.M. a further thirteen ounces. This latter was of amber colour, clear, specific gravity 1010, showed only a trace of albumin, the Esbach being nil. At 5.45 P.M. three more ounces were passed, but at 9.45 P.M. only three drachms. During the afternoon nearly a pint of water with glucose had been taken; an enema had given only a slight fæcal result, and for the first time a fæcal leak appeared at the lateral wound. The night was more comfortable. No vomiting, but no urine. Bowels not opened, but a good deal of fæcal matter was discharged from the lateral wound.

The next day (July 16th) was one of anxiety; happily the blood pressure gradually fell; at 8.40 P.M., 136/98. At 1.20 P.M. an enema gave no result but mucus; there was considerable pain in lower abdomen, and hot bottles were still applied to abdomen and feet. Up to 8 P.M. no urine had been passed, but at 8.20 P.M. ten ounces were voided. During the night seventy-two ounces of urine were passed (12 hours), although there had been no obvious œdema.

From this time on the patient steadily improved. On July 17th the blood pressure was 135/98. There was still abdominal pain. Enemas were given four-hourly. At 7 P.M. there was a good fæcal result; fæces were still coming from the lateral wound, but gradually diminished. During the twenty-four hours 106 ounces of urine were passed. On the 18th the temperature was 100°. Barium was injected into the sinus of the lateral wound under some pressure and the abdomen radiographed. A large barium-filled space in the pelvis with divarications appeared, the barium being apparently mostly extra-intestinal. An enema at 7 P.M. produced formed fæces. Urine 30 ounces. Abdomen not distended. Blood pressure 130/98.

The further progress of the case was uneventful. There was no more vomiting. The bowels were opened naturally; a normal amount of urine, free from albumin, was passed. By July 25th the original wound had granulated over and the midline wound was healed. On August 26th the patient was discharged. The abdomen was flat, though there was occasional leakage from the lateral wound. A Curtis abdominal support was fitted after a few days. Three months later the patient looked extremely well and had gained two stones in weight. The urine was normal.

On May 9th, 1934, he was leading an active life as a milk roundsman. The median scar was in good condition; the lateral scar was considerably stretched, but there was no hernia, though a weakness could be felt on coughing. He wears his Curtis belt all the time. Urine again normal.

REMARKS

1. If at the start this man's abdomen had been opened in the middle line all the troubles which ensued would have been avoided. 2. Unfortunately, plastic peritonitis, limited to the right lower quadrant of the abdomen, with acute intestinal obstruction developed. 3. As a result of the straining and vomiting a block in the renal circulation occurred, producing anuria. 4. This was attributed to a congestion of the medulla of the kidneys, mechanically caused. 5. The choice of treatment for this condition is between decapsulation of the kidney, venesection, and the exhibition of some drug which greatly lowers the blood pressure. 6. Spinal anæsthesia was chosen for two reasons. First, it greatly lowers the blood pressure, and would thus relieve congestion of the renal medulla and allow the cortical activity to begin again. Secondly, it increases peristalsis, by which it was hoped the obstruction would be overcome—at least temporarily. 7. Put to the test, it more than met our expectations. Although but two injections, separated by twelve hours, were given, both the anuria and the gut obstruction were overcome. A recurrence of the anuria indeed looked likely, and perhaps it would have been better to have given a third injection after a further twelve

hours. The renal function however became fully re-established. The intestinal obstruction was completely and permanently overcome. One can only believe that the barrier was somehow broken down, a short circuit perhaps being produced: only in such way can one explain the absolute cure of this condition. 8. Suppression of urine in man is too often fatal. To restrict the fluid intake is easy; to induce a spinal anæsthesia requires but little skill. It is evident that in combination they may be capable of relieving anuria provided it is not due to long-standing disease or to blockage of the ureters.

AURICULAR FIBRILLATION AFTER EMETINE INJECTION

By Ibrahim Abdel Sayid, M.D. Cairo
MEDICAL SPECIALIST, BANI-SUEF HOSPITAL, EGYPT

Emetine injected into a vein weakens the heart's action and induces a fall of blood pressure, but when it is injected subcutaneously or given by the mouth the heart is not affected directly. In his "Pharmacology and Therapeutics," Cushny states that in the frog emetine causes a slowly advancing central paralysis; the contractions of the heart are rendered weak and irregular, and eventually cease from paralysis of the cardiac muscle. In the two following cases the drug appeared to induce auricular fibrillation on subcutaneous injection.

Case 1.—A woman, aged 40, had suffered from amœbic dysentery for two months. A year previously she had had acute rheumatic fever, complicated by endocarditis, and on examination she was found to have an organic systolic murmur over the mitral area, with moderate reduplication of the second pulmonary sound; the left border of the heart was at the nipple line. Pulse-rate 82; blood pressure 120/80. The heart was fairly compensated. She was given emetine hydrochloride 0·02 gramme with strychnine, subcutaneously, each day for six days. Two days after the last injection the auricles fibrillated. Her condition was very bad, but the heart was restored to normal rhythm with digitalis in ten days. Later the treatment of dysentery was completed with Yatren and emetine-bismuth-iodide pills.

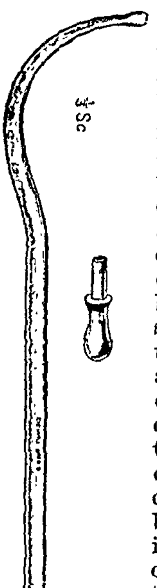
Case 2.—The patient, a man aged 50, had chronic amœbic dysentery. When examined on Sept. 24th, 1934, he showed no signs of cardiac lesions. He was given one grain of emetine hydrochloride plus one milligramme of strychnine daily for six injections; then a course of yatren pills and enemata for ten days; and finally six more injections of emetine. He developed a very bad attack of auricular fibrillation. Normal rhythm was restored with digitalis and quinidine sulphate, but the patient was in bed for about three months, and when I last saw him, in February, the pulse-rate was over 100 and there were signs of myocardial degeneration.

I have observed palpitation and dyspnœa in other cases after emetine, and though the use of this drug is almost indispensable in amœbic dysentery its depressant action on the cardiac muscle is far from negligible. It should therefore be given with great care and only under strict medical supervision.

NEW INVENTIONS

A COMBINED URETHRAL DILATING BOUGIE AND CATHETER

The bougies here illustrated have the shape of the well-known Lister's bougies and in addition each bougie has a narrow tubular channel running through its long axis; they are made in three sizes, 4/7, 6/9, 8/11 Eng. gauge. The bougies are made of brass, nickel-plated, and are designed to obviate the necessity for a metal catheter, in dealing with that common surgical emergency, acute retention of the urine from a urethral stricture. As every surgeon knows, the passage of a bougie through a stricture is much easier than the passage of a metal catheter, even though the stricture has been first dilated by the bougie. The slow emptying of the bladder through the narrow channel in the bougie is an added advantage in this type of case. To the comparatively inexperienced worker, the flow of urine through the channel in the bougie is welcome confirmation of the successful passage of the bougie into the bladder. The bougies have proved very satisfactory in practice, as they are passed more easily than a metal catheter owing to the greater weight, better balance, and their bulbous ends, and I also prefer to use them instead of a metal catheter in cases of enlarged prostate, where occasionally it is necessary to use a metal catheter to relieve acute retention.

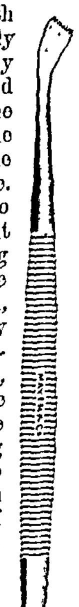


The set of bougies was made to my design by Messrs. Down Bros., London.

Milroy Paul, F.R.C.S. Eng.

A NEW TONSIL DISSECTOR

The dissector, here illustrated, designed for the enucleation of tonsils, has certain advantages, and has demonstrated its usefulness in routine hospital practice during the last year. The smooth tapered end is orthodox, being slightly curved, with semi-sharp edges, used solely for the purpose of incising the reflected mucous membrane of the tonsil, freeing the anterior pillar, the upper pole, and the posterior pillar in turn, preserving the pillars intact, and displaying the capsule. The reversed end is flattened and also slightly curved, terminating in a straight row of very fine serrations, the sides being smooth and semi-sharp. The serrated edge rests on, and is kept close to the tonsil, using it to separate the tonsillar bed gently away from the tonsil. Trauma and subsequent after-pain is reduced to a minimum, as it is impossible to injure the bed of the tonsil, and each movement that is made accomplishes its object, especially avoiding as far as possible repeated attempts to overcome the tough fibrous tissue in adults, who have had several attacks of inflammation, or quinsies. Also, incidentally, the length of anæsthesia is shortened. Hæmorrhage rapidly ceases, in most cases without ligaturing, and a smooth tonsillar bed remains. The dissection of tonsils in children is rapid and easy, with freedom from shock and post-operative bleeding.



Messrs. Mayer and Phelps, of New Cavendish-street, W., have kindly made this dissector for me.

E. Gwynne-Evans, M.B., B.S. Lond.

REVIEWS AND NOTICES OF BOOKS

Principles and Practice of Preventive Medicine

Edited by C. W. HUTT, M.A., M.D., M.R.C.P., D.P.H., Medical Officer of Health, Borough of Holborn; and H. HYSLOP THOMSON, M.D., D.P.H., Medical Officer of Health, County of Hertford. London: Methuen and Co., Ltd. 1935. Two vols. Pp. 1688. £3 13*s.* 6*d.*

THE publication of a comprehensive and authoritative work on preventive medicine from the British standpoint has been long overdue, and the two volumes edited by Dr. Hyslop Thomson and the late Dr. Hutt will not disappoint those who have been eagerly awaiting such an event. While the whole field of medicine and surgery is in one sense preventive, the term "preventive medicine" in the present book is restricted to what is commonly known as public health and hygiene, with the additions which a widening view has tended recently to include. Thus the older practitioners of public health might feel astonished at finding chapters on malignant disease, electricity and radiology, town and country planning, heredity, and hygiene in aviation in a book on preventive medicine, yet, with the possible exception of the 25 pages on electricity and radiology, no one would now cavil at their inclusion.

The book consists of 50 chapters, each on a distinct aspect of preventive medicine, contributed by 47 authorities on their respective subjects. It has been well coördinated by the editors and does not give that impression of diversity of aim and lack of balance so often found in composite books. The law dealing with each subject is collated at the end of its section and main references for further study follow each chapter. With a single exception (the ventilating fan on page 983) all the illustrations are good and to the point. Noteworthy chapters are those on infection, epidemiology, and immunity, by E. H. R. Harries—although perhaps the subject of bacteriophage is given undue prominence; on water and particularly on the hygiene of swimming baths, by Prof. J. W. Wilson; on refuse disposal, by G. Clark Trotter; on heredity, by Prof. F. A. E. Crew and Fraser Roberts; on insects and vermin, personal hygiene, and popular education in health, by the editors.

There are few omissions and still fewer misstatements. No mention seems to have been made of electric fires in the section on heating, nor has the importance of excluding "totters" and other trespassers from refuse dumps been alluded to in discussing refuse disposal. The paragraphs on the domiciliary treatment of poor-law patients might have explained more fully the various terms of service under which district medical officers work, and the maternal mortality-rate is not mentioned in the chapter on vital statistics nor is it defined, or the possible fallacies in it discussed, in the otherwise excellent chapter on maternal welfare. It is unfortunately not yet true that "*most* local supervising authorities provide post-graduate classes for midwives free of charge." Slips in proof-reading are remarkably few. The index, which occupies 109 pages of small print, makes reference both pleasant and easy.

This book will take its place as a standard textbook on public health and no medical officer of health can afford to be without it. To those whose appetite may have been stimulated by the lectures on the preventive aspects of medicine at King's College Hospital, which appeared in our columns for the greater part of a year (Oct., 1933–June, 1934) and were later published in book form, it will provide a most satisfying meal.

The Crippled and the Disabled

Rehabilitation of the Physically Handicapped in the United States. By H. H. KESSLER. Columbia University Press. London: Humphrey Milford, Oxford University Press. 1935. Pp. 337. 20*s.*

Dr. Kessler, though it does not appear on the title-page, is medical adviser to the New Jersey Rehabilitation Commission and to the Workmen's Compensation Bureau, and his book is a much more comprehensive survey than its title suggests. It attempts to outline critically the methods of dealing with all types of the physically and mentally unfit which have developed in modern times both in the United States and in Europe. The subject is divided into groups of the disabled—children, the industrially disabled, the chronically disabled (that is, those suffering from chronic disease), the war cripples, and the group of defects of special senses, and in each group the development of methods of treatment and of "rehabilitation" is studied in detail. There is a wealth of material which has been laboriously collected and ably presented, while the legislative details for the various States given in an appendix will greatly help the student.

The book condemns the social prejudice against the disabled. The term "disabled," Dr. Kessler writes, "is used to designate several groups of persons who are definitely handicapped in their effort to make a living because of physical disabilities of one sort or another." And he claims that we are all under a false impression as to what constitutes disability. "There is no such entity as a normal person, and many persons who are looked upon as disabled are by no means less capable of meeting the economic and social requirements of life than many apparently healthy persons." If this is meant to imply that because functional capacity does not prove organic health (which is admitted) organic disablement therefore does not prove functional limitation, we think the logic is faulty and unlikely to provide a satisfactory basis on which to work out large schemes for the disabled. While we are all in sympathy with the suggestion that it is the duty of the able-bodied to care for the well-being of those less fortunate, we cannot think that it is either economically possible or socially desirable, especially at the present crisis, that the disabled should be provided with work at the expense of those who are physically fitter. Work is no doubt the best stimulus, physical and mental, to the partially incapacitated; their morale suffers if they feel they are handicapped by the fact of disease or disablement, and they tend to develop (to use an Adlerian term) an "organ inferiority." But where it is a question of competition, it may be even worse to deprive an able-bodied man of his job; he is just as liable to feel inferior if he has no work, especially if replaced by one obviously less "fit" than himself. In particular does this apply to elderly people with chronic disease, who have had their good days, and to those suffering from incurable and progressive conditions. We may regret their disability, and yet feel that the needs of the community are better served by caring for and protecting these people rather than by allowing them to compete in the open market. In contrast to this no one will fail to approve all the measures described as existing, or suggested as possible, for bettering the condition of the child cripple. Here the ultimate goal is the production of self-supporting citizens, and this can only be achieved by the combination of careful physical treatment, special education facilities, vocational training, and (last and most important) the "placement facilities and a method of close follow-up" which Dr. Kessler finds in London and not nearer home.

An interesting comparison is drawn by the author between the methods of dealing with the disabled. In the U.S.A. there is a wealth of legislation, the law and the State provide for the industrially or war disabled all along the line; he passes out of the hospital ward at an early stage into a congeries of other centres and agencies. The haphazard measures of this country are dismissed by the author in the sentence "The compensation laws of Great Britain contain no provision for rehabilitation. Such activities are carried on by private and philanthropic schemes," and he remarks "The United Kingdom does not have a compulsory employment act for disabled workers." It is true enough that services of this type have developed here on voluntary lines, but they are not any the worse for the element of personal service. The U.S.A. may be congratulated too on such voluntary associations as the Goodwill Industries which started in Boston from small beginnings and has developed far-reaching and self-supporting workshops which provide employment for many disabled. Similar to it is work of the Winifred Masterson Burke Relief Foundation, whose eleventh biennial report, just received, is testimony to the completeness of its equipment.

Medical Annual, 1935

Edited by H. LETHEBY TIDY, M.D., F.R.C.P., and A. RENDLE SHORT, M.D., F.R.C.S. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. *Pp. 596. 20s.*

Medical Annual General Index and Review, 1925-34

Same publishers. Pp. 450. 12s. 6d.

THE "Medical Annual" is too familiar to need description and too good to need recommendation. It succeeds extraordinarily well in presenting the new things of practical interest and value sorted out from the welter of the year's literature, and it does so with just enough discrimination, just enough detail, and just enough comment and synthesis from its able and experienced contributors, to make it invaluable to any doctor who wishes to be up to date in more than the narrowest of specialties. Five new names appear in this year's list of reviewers: Dr. Ivor Davies succeeds the late Vincent Coates in the section on rheumatic diseases; Dr. L. S. T. Burrell deals with pulmonary tuberculosis; and Mr. K. H. Pridie with orthopædic subjects. Dr. L. P. Lockhart writes a special article on medicine in an industrial state, and Mr. D. Harcourt Kitchin another on medico-legal problems and recent legal decisions. The editors have the impression that the progress of medical knowledge is speeding up; if so, the value of their Annual, which is a credit both to the English profession and to English medical publishing, is increasing.

This year there also appears the decennial general index, which, in addition to indexing all the headings in the last ten annuals, has a short finger-post article by each of the 30 reviewers, surveying his field and pointing to the spots where growth and development have been most active.

Triple Challenge

Or War, Whirligigs and Windmills. A Doctor's Memoirs of the years 1914 to 1929. By HUGH WANSEY BAYLY, M.C. London: Hutchinson and Co., Ltd. 1935. Pp. 396. 18s.

THE sub-title of this book, though not very definite, gives a good idea of the generous hotch-potch ladled out by Mr. Wansey Bayly. He has plenty of material, especially in his account of the war years, to make an intensely interesting book; but like many historians he cannot bear to discard the personal implications of his narrative, so that a sense of proportion is lost. For instance, he may describe how he lost his hat with as much circumstance as he does the Dogger Bank action. Those who can pardon these irrelevancies, however, will find the war chapters full of valuable information, as well as of stimulating writing. The author's patriotism takes a form which many will approve of and many will not—a fact that may rouse a spirit of controversy in the reader and sustain his interest in the political excursions. The closing chapters of the book deal with the attempt made after the war to provide facilities for educating the public in the prevention of venereal disease, and Mr. Bayly writes with inside knowledge of movements in which he took a prominent part, never disguising his own strong views.

The book is embellished with war pictures, one of which is a photograph of the hull of the *Blücher*, crowded with men, within a few moments of her sinking. The episode will give for some a sufficiently appalling answer to an appeal to ready militarism; on others a different impression may be produced.

Furneaux's Human Physiology

Revised by WILLIAM A. M. SMART, M.B., B.Sc. Lond., F.Z.S., Senior Demonstrator of Physiology; Lecturer in Pharmacology and Toxicology, London Hospital Medical College. London: Longmans, Green and Co., Ltd. 1935. Pp. 348. 4s.

FEW books contain so much in a small space as this excellent little manual, which includes a great deal of anatomy as well as physiology. The present edition is completely revised and intended primarily for the use of nurses. An account is given of all the systems of the body, and the exposition is brief, dogmatic, and to the point, all kinds and sizes of print being used for emphasis and the introduction of new words. An attractive feature is the inclusion in parentheses of Greek and Latin roots with their original meanings, and "the consideration of the evolutionary, comparative, and philosophical aspects of the subject." This quotation from the preface is a little ambitious considering the size of the book, but a praiseworthy attempt has been made to make it an introduction to biology as well as a text-book, and culture has not been entirely neglected in the cause of instruction. No secret is made of this as the main object however, and there is a summary at the end of each chapter and examination questions at the end of the book. As the book is designed for nurses (a special edition for schools exists, without the chapter on reproduction), it might perhaps have dealt a little more fully with the principles of dietetics and temperature control, though the author would be entitled to retort that to extend its scope further might be injudicious. Controversial points are, of course, treated rather cavalierly, and the purist might quarrel with one or two statements, but actual mistakes are few. One is the reference to *œstrin* as the active agent in the Aschheim-Zondek test for pregnancy.

THE LANCET

LONDON: SATURDAY, SEPTEMBER 7, 1935

BOTULISM

AFTER an interval of almost exactly thirteen years the public have been startled by the occurrence of another group of deaths due to botulism. Since the Loch Maree tragedy in August, 1922, when eight persons died within a week in the West Highlands of Scotland, there have been no cases in this country officially certified as such, though several times suspicion has arisen. In Scotland there is no such thing as a coroner's inquest, but the Scottish Board of Health instructed two of its medical officers to make an extensive investigation, the results of which were later published in a book[1] which has remained the classical account of the disease. The poisoned food in the Loch Maree case was wild-duck paste in a glass container; the four persons whose death was investigated by the St. Pancras coroner last month (see p. 584) had eaten nut brawn, a vegetarian product made in London, also from a glass container. In neither case was there any indication that the food was abnormal or unfit for consumption, and in both of them the verdict acquitted the manufacturer of any neglect. In closing the inquest on August 23rd the coroner said there was no suggestion that food in bottles was any more dangerous than food in tins. The closing of the inquest, he added, would not mark the end of the attempt to find where the infection came from; three separate investigations are in hand and it will necessarily be some time before they are complete.

Botulism may be described as infection by a specific microbe, the *Bacillus botulinus*, which gains access to a mass of food material, and there, under very definite and special conditions, produces by multiplication and growth its deadly toxin. This toxin is consumed with the food and is responsible for the characteristic symptoms. The mere consumption of the organism itself is not sufficient to cause botulism; the ordinary conditions of the alimentary tract are not those in which it flourishes. The brilliant researches of K. F. MEYER and his colleagues in California established the fact that the *B. botulinus* is widely distributed in the soil. They analysed 1533 soils of various kinds—335 virgin soils, 274 cultivated soils, 142 garden soils, 161 soil and manure, 51 pasture soils, 570 from vegetables and feeds. Virgin soil, that is, soil unconnected with human habitation, domestic animals, or any form of cultivation, yielded the greatest number of positive results, no less than 37 per cent. containing the organism. Some of these were from mountains 12,000 feet high. Garden soils gave 41 positive out of the 142; soil and manure from animal yards, 20 out of 161; pastures, 19 out of 51; and of the 570 samples of soils under the heading of vegetables and feeds 134 were contaminated. The organism is thus most common in pasture, virgin, and vegetable soil; it is least common in cultivated, garden, and manured soil. Soils from many countries have since been examined, including England, Scotland, Denmark, Holland, Switzerland, Hawaii, and China, with similar results. The *B. botulinus* is apparently present in the soil everywhere. The resistance to heat of the spores from various strains of the organism varies considerably, but MEYER gave the maximum resistance to moist heat of the spores obtained from foods concerned in 26 human outbreaks as follows: 4 minutes at 120° C., 10 minutes at 115° C., 33 minutes at 110° C., 100 minutes at 105° C., and 330 minutes at 100° C.

The clinical picture of an acute case of botulism in man is characteristic and very terrible. There is no well-defined incubation stage. The patient may show no symptoms until he suddenly complains of double vision, caused by commencing paralysis of the muscles of the eyeball. Some have abdominal discomfort before this and there may be vomiting. Then follows more or less complete paralysis of the eyelids, producing ptosis. The patient will lift up his eyelids to see. Then the speech becomes blurred and indistinct. The pupils may or may not be dilated. In attempting to walk dizziness is shown by a staggering gait. Pain is absent at this or any other stage, but there is great discomfort and increasing distress. As a rule constipation is obstinate. There is no rise of temperature and no headache. Further paralytic symptoms soon follow. Difficulty of swallowing supervenes along with other signs of throat paralysis. The larynx is affected and speech becomes impossible. The patient, however, remains in full possession of his mental faculties and conscious of his own state and surroundings. He can even communicate freely by writing, though not by speech. Later air-hunger comes on, partly due to accumulation of mucus which cannot be swallowed or expelled, the various respiratory muscles weaken, including the diaphragm, and finally paralysis of the heart sets in, death occurring 36–72 hours after the onset. It will be noted from the symptoms that the toxin attacks mainly those cranial nerves which supply muscles, while those of special senses, such as hearing, seeing, smelling, are not involved. The mortality is very high. MEYER records 249 deaths in 396 cases, a rate of 62·8 per cent. It may be 100 per cent. in some outbreaks.

In spite, however, of the fact that *B. botulinus* is found in soils all over the world, botulism is one of the rarest of diseases in human beings. It is relatively more common in parts of the continent and in America than in this country for reasons well understood and connected with the national food habits of the people. In Germany the majority of the outbreaks have been associated with the eating of foodstuffs, such as sausages, which have not been thoroughly cooked, but only smoked. In America a number of cases have been associated with the canning or preserving at home of fruits and vegetables. Some of these home-preserved foods are consumed raw, as they come from the container—e.g., spinach and asparagus. American authorities are of opinion that the heating of preserved foods to a temperature of 80° C. is sufficient to destroy the toxin, and therefore to prevent botulism. Thus, it is to be noted, although the spores of the bacillus are highly resistant to heat, the deadly toxin is readily destroyed by temperatures commonly used in preparing foods. These and other facts, which have been worked out by bacteriologists and those concerned in canning processes, are now well known and duly provided for. The temperatures used by manufacturers of tinned foods are well above those necessary to destroy the toxin, and designed to kill the spores as well. They are, of course, far above any temperatures reached in domestic methods. The result is that, despite the millions of tins of food manufactured and consumed all over the world, botulism remains a rare condition, and, it is safe to say, will always remain so. Perhaps because of its rarity an outbreak causes concern and alarm out of all proportion to its prevalence.

THE BIRTH OF MEDICAL DEFENCE

This is the jubilee year of the Medical Defence Union and the annual report issued to its 18,000 members tells the story of its origin. In the year 1883 two Dulwich practitioners, Dr. Edmund Bower and Dr. W. Cooper Keates were prosecuted first for negligence and then for manslaughter in consequence of their treatment of a child. It was a case of diphtheria with increasing obstruction in which the two doctors performed a tracheotomy and the father was asked to remove the obstruction by oral suction, which he did. Unfortunately he contracted diphtheria and to compensate himself against suffering and pecuniary loss he brought an action for negligence against the doctors. This failed and he then brought an action for manslaughter which was dismissed by the magistrate, without calling upon counsel for defence, with the remark that the case was one of persecution not prosecution. But the two doctors were by this time more than £1000 out of pocket, and this was felt by their fellow practitioners to be so unfair that a meeting was called at which Sir William Jenner presided and considerably more than that sum was raised by public appeal. At this meeting a resolution was passed asking the Royal Colleges to press the Home Office to make some arrangement by which the public prosecutor might obtain the assistance of skilled advisers when called on to proceed against medical practitioners. A leading article in our columns at the time complained that the director of criminal prosecutions had "lent the weight and sanction of his great authority to the parading in a court of justice of such matters as the merest tyro in forensic medicine would have grasped and settled in a trice."

At that time the only medical defence association was a small affair which had never ventured to defend a medical practitioner in a court of law. The British Medical Association was therefore pressed by many of its branches to provide individual medical defence for members, but the Association was advised by counsel that its funds could not legally be used for that purpose. Hence it was that on Oct. 23rd, 1885, a Mr. C. F. Rideal and six other laymen registered the Medical Defence Union as a company limited by guarantee under the Companies Act of 1862 with offices at 16, Bedford-row, London. The early years of the union were difficult. It enlisted the support of that forceful but wayward personality, Mr. Lawson Tait, who became president of the union in 1887; but in the same year the union was nearly wrecked by the perfidy of one of its own staff, and its office was transferred to Birmingham, where Dr. Leslie Phillips was one of the joint honorary secretaries, Dr. A. G. Bateman remaining in London as the other. Both were hard workers and many cases in which medical men were threatened with legal proceedings were withdrawn, although it was not actually until 1889 that an action was fought in the courts, when damages were recovered from the Great Western Railway Provident Society for the wrongful dismissal of a surgeon. In the next year the framework of the union was revised with a view to ensure more continuity of method, but there were some among its members who feared the change and set up the London and Counties Medical Protection Society, with Dr. Hugh Woods as one of its secretaries. The question of amalgamation was raised again and again, but nothing came of it, and now that the two societies have worked for so long side by side, with competition acting as a healthy stimulus to progress, it is perhaps no longer needful to regret these early quarrels. In 1893 Lawson Tait was succeeded in the presidential chair by Sir Victor Horsley who found there another outlet for his brilliant powers of organisation. Again in the following year a rift was threatened within the union, for many members resented the council's decision to defend one of their number against his former assistant, who was also a member of the union. The dispute was however settled by the adoption of the principle that the union would not ordinarily defend or support an action between members of the medical profession and that disputes between members of the union involving a breach of contract should be referred to arbitration. That was the last growing pain before the union entered on its maturity, interrupted only by a momentary tremor in 1903 when the British Medical Association reconsidered its decision not to provide individual medical defence for its members, but again turned it down.

The ideals of the Medical Defence Union, as the report indicates, are now happily expressed in its telegraphic address "Damocles" and in its motto "Dextra Dare." The union expects each of its members to pay his subscription as a personal insurance premium to avert the stroke of the sword; but it also expects him to give it with his right hand, or in other words, with the same sympathetic motive of help to his brother practitioners which inspired the medical profession when it came so magnificently to the assistance of Dr. Bower and Dr. Keates. It is in this respect that the work of the union differs fundamentally from that of an ordinary insurance society. In the face of a substantial claim the directorate of an insurance society naturally considers every possible way of avoiding it, the object being to exclude as many claims as possible; the council of the union does its best in every case to bring the applicant within the union's sphere of action, the members of the council putting themselves in the position of the applicant in trouble. To this difference in practice Mr. Oswald Hempson, speaking at a jubilee dinner of the council, ascribed a large part of the union's success; it was this, he said, that had made his work as solicitor to the union, and that of his father before him, seem so well worth doing.

INSULIN IN MALNUTRITION AND INFECTION

The use of insulin apart from diabetes has never found much favour in this country, but elsewhere this remedy—so powerful in its own place—has been declared valuable in a variety of diseases. It was not unreasonable at least to hope that it might rectify some of the metabolic disturbances associated with acute infections, and Schwentker and Noel[1] have in fact recorded excellent results from its administration, with glucose, in hypertoxic diphtheria. Their results were so startling that the work was repeated in this country by Benn and co-workers.[2] But though these reported favourably on the effect of such treatment, they could record no such remarkable successes; and N. D. Begg's recent investigations[3] suggest it is the dextrose, not the insulin, that is helpful in diphtheria. A second suggestion, that insulin should be prescribed for undernourished patients, finds support in the demonstration by Okada and others that insulin increases alimentary secretion; from which it might be expected that assimilation of food would be accelerated. Joslin[4] believes that thin undernourished people whose emaciation is due to poor appetite can be induced by insulin to take more food, and speaks of its use in non-diabetic cases of tuberculosis. Its mode of action, he admits, is not entirely clear. Freyberg,[5] for his part, leans to the view that the rise of weight sometimes obtained is wholly a result of increased ingestion of food, due to insulin causing contractions of the stomach, and even hunger pains. But most patients do not seem to have such gastric contractions and we are left without full explanation of the remarkably good results obtained by Falta and some others who have used insulin for malnutrition in adults.

Freyberg's own investigations now reported lead him to doubt whether insulin is valuable to the undernourished, and he remarks that "the number of satisfactorily controlled investigations of the value of insulin in undernutrition is conspicuously small." His studies are divided into two parts. The first concerns a group of 9 thin patients, 5 of whom were suffering from afebrile pulmonary tuberculosis, while the other 4 were psychoneurotic. Precautions were taken to prevent their knowing that they were receiving insulin and that an increase in appetite or hunger might be expected. The average duration of the experiments was twenty days and the average amount of insulin per patient was roughly 35 units daily. Of the 9 patients studied, 7 showed no increase in appetite, food-consumption, or rate of gain in weight—indeed 5 of them actually lost weight—and only 1 showed a weight increase. In the second part of the investigation an attempt was made to fatten patients and measure separately the effects of (1) a high caloric diet, (2) the diet plus injection of a placebo, and (3) the diet plus insulin. Of 11 patients studied in this way only 3 showed a response that could be attributed to insulin; in one of these, moreover, a high caloric diet was just as effectual, and in another it was found impossible to reproduce the beneficial effect when a second course of insulin was given. In all, therefore, only 2 patients out of 20 showed any improvement attributable to insulin, and it has to be recorded also that in 2 cases a placebo was apparently more effective than insulin in raising weight. Freyberg's data show clearly a close correlation between caloric intake and weight changes, and he believes that only when insulin produces hunger pains can an increased caloric intake be anticipated. Unfortunately one may have hypoglycæmia without hunger pains, and this leaves an opening for serious risk. Joslin refers to another danger when he points out that "individualisation of the dosage should be emphasised especially in cases in which tuberculosis of the adrenals or liver is present."

The last word on this subject has certainly not yet been said, but Freyberg's investigation is justified, if only because it shows what can be achieved in the treatment of undernutrition by suggestion.

St. Bartholomew's Hospital Extension.—A special block for paying patients is to be built at this hospital, probably on the opposite side of Little Britain from the hospital itself. The funds for this block must come from outside sources, not from general funds, and from 90 to 100 beds are to be provided at a cost of something like £140,000. Thirty per cent. of the accommodation will be set aside for patients able to make some, but not full, payment, and this deficit may be made up out of the general fund.

ANNOTATIONS

ECONOMIC CATERING

THE Nutrition Committee of the British Medical Association issued its first report in 1933, as a supplement to the *British Medical Journal* of Nov. 25th. The committee had been appointed six months previously, its terms of reference being "to determine the minimum weekly expenditure on foodstuffs which must be incurred by families of varying size if health and working capacity are to be maintained, and to construct specimen diets." Our readers will remember the reasons set out for choosing 3400 calories instead of 3000 calories (Cathcart and Murray) as the standard man-value requirement, and the controversy which followed the difference between the estimates made by the committee on this basis and those made by a committee of the Ministry of Health. The B.M.A. committee obtained food prices from two sources: (1) some very detailed records available from Stockton-on-Tees, where inquiries had been made weekly over a period of two years from 16 grocers and 9 butchers patronised by working-class families; (2) lists supplied by certain medical officers of health of the prices current in their areas during two weeks in the summer of 1933. Using the mean of each of these sets of prices, 16 specimen weekly diets were compiled showing for each item its quantity, its price according to each standard, its content in protein, fat, and carbohydrate, and its caloric value. There remained the need to convince the public that such diets could actually be procured in the market at something like the estimated cost, and when prepared for consumption would give satisfaction to the families concerned. At the time no attempt was made to work out menus or to give advice on the cooking and preparation of meals, although the committee believed such a measure to be practicable and desirable if the housewife was to make full use of the information supplied in the report. They have now, in response to many requests, issued practical instructions which paraphrase their general scheme in terms of foodstuffs to be bought in the market, with detailed menus and recipes.

A pamphlet on family meals and catering which begins with a Sunday dinner of roast beef, Yorkshire pudding, green vegetables and potatoes, followed by rice pudding, disarms at least one common criticism against diets planned to the greatest economical advantage—that they are often composed of ingredients unfamiliar or unpalatable to the British public. The cold beef for Monday's dinner, followed by shepherd's pie on Tuesday, in the first week's menu is indeed so stereotyped in our homes that at first sight it may seem that the housewife will learn little that she does not already know. But the implied assurance from an influential quarter that on the whole she is already making the best of her resources, and the fact that the recipes are for the most part comparable with those already available in simple cookery books will encourage her to examine the differences and to take full advantage of those suggested on economic grounds. The diet chosen for exemplification is No. 16, designed to meet the requirements of a family consisting of a man and wife with three children, aged 6–8, 10–12, and 12–14. The items of this diet, according to the original Nutrition Committee report, represented a total caloric value of 97,863, the daily quantity of calories per man being 3385. The total first-class protein worked out to 1420 grammes and the daily first-class protein per man to 49 grammes. The cost of the food per man per week was *53·6d.* (Stockton mean) and *65·5d.* (B.M.A. mean), and the minimum weekly cost of the family's food *18s. 5¼d. or 22s. 6½d.*, according to which set of food prices was accepted. The items detailed, in the same quantities, are now set out in shopping lists for three consecutive weeks, with menus for midday dinner and high tea or supper for each of the 21 days. The shopping lists include certain items, such as kippers and corned beef, which do not appear in the menus and are presumably used for breakfast, while the fact that more oatmeal is bought each week than is used in the recipes suggests that the modern fear of porridge as a rickets-favouring article of diet is not shared by members of this committee. The fact that only 3 eggs are bought in each of the first two weeks and only 6 in the third week (where 4 fried eggs and onions figure on the menu of an evening meal from which the youngest child is apparently excluded) directs attention to such items as potato omelette and to the custard which presents an appetising suggestion for two of the Saturdays; it emerges that the "omelette" contains no eggs and that the custard is derived from custard powder.

It would be improper to cavil at the fact that throughout this pamphlet there is no mention of the cost of any items except such vegetables or fruits as may be bought in pennyworths—the amount allocated to these being *2s.* each week. We may assume that the shopping list has been tested by actual trial in appropriate districts, and that the price of the ingredients has been found to correspond roughly with the sum allocated to food for this family in the report. Precision in specifying actual prices in named districts would, of course, have been of considerable interest; and the further omission of any hints for the planning of an adequate breakfast has the disadvantage that the housewife is left without guidance to the proportion of her budget to be allowed for this meal. The reason given for not stating prices is that they vary so much from place to place and from time to time. This has always been the contention of those who hold that any attempt to give advice in terms of actual purchases must fail, and the omissions in this beautifully produced pamphlet may serve to confirm their scepticism. On the other hand, the table of quantities of each of the foodstuffs named in recipes and the notes, for the use of teachers of domestic science, of their food values in terms of content of protein, fat, and carbohydrate, and of their caloric value per lb. will be generally appreciated. The pictorial arrangement of each main meal, daintily set out in casseroles or well-matched china on a spotless tablecloth, suggests the comparative leisure of a cookery student rather than that of a harassed housewife; and the attractive plates are in fact coloured reproductions of dishes cooked according to the recipes by students of the National Training College of Domestic Science in London in their second term.

This pamphlet will have a permanent value in providing schools of domestic science for working-class people with standards which are applicable in the homes of the pupils without modification. It can be obtained by such schools at *3s. the dozen* copies, that is, at half the price of the separate copies, on application to the financial secretary of the British Medical Association.

OBSTETRICS IN DUBLIN

THE reputation of Dublin as one of the leading obstetric schools of the world has been maintained not only by the enthusiasm of successive generations of students and practitioners grateful for its practical teaching, but also by the clarity with which the clinical results obtained at the three maternity hospitals are every year correlated and presented. In the London hospitals no doubt the amount of supervised obstetric work is much larger, but most of this work is recorded and laboriously tabulated by the obstetric registrars, to little purpose. The medical reports from the three maternity hospitals of Dublin are presented to the section of obstetrics of the Irish Royal Academy of Medicine where the fruits of their discussion may be even more instructive than the reports on which it turns. Under its new master, Dr. Andrew Davidson, no drastic change has been made at the Rotunda in the methods and principles which have proved of value in the past. The maternal mortality remains at a commendably low level: in 1934 it was only 0·83 per cent. with a morbidity-rate of 4·2 per cent., despite the large number of complicated cases admitted. In the past 15 years this institution has been responsible for the supervision of some 57,000 confinements with 267 deaths, the percentage mortality being 0·46.

This year discussion at the section was concerned chiefly with some aspects of midwifery which are at the moment much in the public eye. Breech presentations, it seems, present no terrors to the Rotunda staff. External cephalic version was performed successfully in 19 cases, 18 infants being born alive. The fœtal mortality was however even less when the breech presentation was uncorrected, for then there were only 2 dead infants out of a total of 62. Such a record reflects the greatest credit upon the conduct of these cases. None of the reports throws much light on uterine inertia, which is by far the most ticklish problem that faces the obstetrician to-day. Dr. Davidson hopes that hormone therapy may provide the solution. Dr. Gibbon FitzGibbon simply asks that each case of this nature should be reported in detail. The treatment of 23 cases of placenta prævia was varied; last year's excellent results were not repeated. The vexed question of disproportion claims most attention in the reports. The master of the Rotunda condemns routine induction of labour by puncture of the membranes in such cases, but he believes it has its place. In the past however labour had certainly been induced unnecessarily; greater knowledge was needed of the conditions under which it should be done. The masters of the Coombe and of the National Maternity Hospital both appeared to concur, but several who took part in the discussion questioned whether induction of premature labour for supposed disproportion was ever justifiable in the primipara. Dr. Davidson thinks that external pelvimetry will often draw attention to cases of contracted pelvis, and that internal pelvimetry, combined with an estimate of the weight of the infant, will help materially to strengthen the judgment regarding the prognosis for delivery. There is much difference in the recourse to Cæsarean section at the three hospitals. It was done 26 times at the Coombe, 2·2 per cent. of all deliveries; 41 times at the Rotunda, 0·6 per cent. The master of the Rotunda would have it resorted to only when the indications are absolutely clear; under the very best possible circumstances the risk is at least three times greater than that of vaginal delivery under the worst possible circumstances—a very pointed warning. Eclampsia was treated upon the lines that have long been advocated in Dublin and the mortality remained at about the level of 10 per cent. At the Coombe the practice continues of allowing delivery without any attempt to save the perineum.

A YEAR'S SURVEY OF CRIME

OFFICIAL figures about crime are generally soothing. If the tables register decreases, we can share in the credit due to a better world. On the other hand if crime is going up, we can still believe that things are not really worse—it is only that our excellent police are more alert in bringing rascals to justice. Part of the soporific effect produced by official statistics may be due to other causes. The annual volume for England and Wales, just published (Cmd. 4977, 3*s.* 6*d.*), gives us the figures for 1933—a receding period in which our interest is diminishing; will the Home Office never manage to catch up this twelve months of arrears? There is something unexhilarating too about the way in which the information is presented. An introduction of 13 pages is all too short and too jejune. The speculative comments which were prefaced to these annual volumes a few years ago have apparently been cut down in the interests of economy. We could better have spared the tedious 40 pages which tabulate all the possible crimes we can commit; the curious can cull this information from the statute-book or from manuals on the criminal law. The very figures themselves refuse to be sensational. Take, for instance, the steadiness of inquest statistics. In 1928 (the first full year after the amending Act of 1926) there was a total of 31,553; in 1933 it was almost unchanged at 31,669. Here, however, one fact of interest can be extracted. The post-mortem examination without inquest, made possible by the 1926 Act, is proving its value. For every six such cases in 1928 there were eight in 1933. There has been no conspicuous rise in non-jury inquests in the same period.

Crime as a whole fell in 1933 below the figures for 1932 which was in some ways a peak year. If the experts rightly relate this improvement in part to the decrease in unemployment, it is yet notable that attempted suicide is still going up. Last year's figure was a record for this offence. In the volume for 1930 we were officially told that in recent years it was not the practice to prosecute for attempted suicide unless special reason existed—e.g., to keep the offender in custody for his own protection. Since 1925 a person charged with this offence can be dealt with summarily instead of being sent for trial. This change may have increased the number of cases brought to the knowledge of the police. We observe that the only other offence where discretionary latitude exists is that of Sunday trading. Over 30,000 persons were found guilty of it in 1933, but a footnote to the table tells us that in most districts it is not the practice to prosecute for Sunday trading: in the exceptional areas, it seems, a few traders cheerfully run the risk of repeated fines. The murder figures are, as usual, steady. Of the 58 persons arrested on this charge in 1933 one committed suicide on arrest and another before trial; one was certified insane before trial; five were found insane on arraignment, and sixteen were found "guilty but insane." We get a hint here of the price we pay for the defects in our system of diagnosing and treating mental disease. If we turn to the figures of criminal lunatics detained on Dec. 31st, 1933, we find that 439 were so detained where the charge was murder; no fewer than 104 of these had then been in institutions like

Broadmoor for 20 years and over. The corresponding figures for attempted murder, felonious or malicious wounding, rape, indecent assault, and other offences make equally lamentable reading.

The criminal statistics of the year as a whole must be correlated with the changes of population. If juvenile delinquency is increasing, it must be remembered that there were more boys and girls between the ages of 10 and 14 to commit offences. Even when this allowance is made, it is sad to find that children and young persons are becoming more ill-behaved. If the year 1933 is compared with the year 1911 and the number of indictable offences is adjusted to the relative totals of population, we find that a figure of 288 (per 100,000) for boys and girls under 16 charged with indictable offences has leapt up to 370 in 1933, whereas the corresponding figure for older persons has dropped from 232 in 1911 to 189 in 1933. In part this increase may be due to the development of juvenile courts and to the growing recognition of the fact that the treatment of the juvenile offender is dominated by regard for his own best interests. The increase in young persons' offences is largely connected with charges of larceny, which may often be trivial enough. There is also an increase in sexual offences committed by young persons from the age of 16 to 21. One happy feature repeats itself in 1933—namely, the comparative good behaviour of the female sex. Whether it be due to natural virtue or to the sheltered life, the proportion of offenders is nearly eight times higher among males than among females.

ECLAMPSIA AS AN ENDOCRINE DISORDER

IN spite of a vast and ever-swelling literature, the cause of eclampsia and the pre-eclamptic toxæmia of pregnancy remains obscure. This is not for lack of speculation. "Theories" of eclampsia and appropriate régimes of treatment are numerous enough, though none can yet hold its own on a basis of direct evidence. In particular, attempts to demonstrate that the disease is an expression of disturbed endocrine balance have multiplied of late years, and attention has been directed naturally to the pituitary. Evidence for and against the idea of an over-secretion of the pressor hormone of the posterior lobe was summarised in these columns just a year ago,[1] when we concluded that the hypothesis must at present be regarded as unproven. More recently attention has been transferred to the anterior lobe of the gland and some observations of G. Van S. Smith and O. W. Smith[2] deserve careful attention. These workers have investigated the distribution of prolan and œstrin in various tissues and fluids during normal and abnormal pregnancy. In normal pregnancy, they say, the prolan content of blood and urine rises during the early months, falls sharply at the fourth month, and thereafter remains fairly constant; whereas in toxæmia the level remains high even when symptoms do not develop until the sixth or seventh month. The œstrin content of the blood and urine, on the other hand, displays a steady rise throughout normal pregnancy, reaching a peak at term, and in cases of toxæmia the rise is often delayed. The next step in the Smiths' investigation was to analyse the placenta for the same hormones. Here also they find that there is an excess of prolan and a paucity of œstrin in cases of toxæmia. And they conclude that it is the placenta rather than the pituitary which produces the extra prolan.

The immediate value of these experiments lies in the fact that they suggest a means of detecting toxæmia before clinical symptoms appear, though it remains to be seen whether such a test will prove a practical proposition. The underlying significance of the observations is another matter, and it is not likely to become apparent until more is known about the nature and functions of the various hormones concerned. So far at least six factors—namely, prolan A, prolan B, œstrin, progestin (corpus luteum principle), oxytocin, and vasopressin—are known to play some part in the sexual cycle and pregnancy. Even if no further principles are discovered an equation involving six factors, none of which is constant, is not easily solved. The present observations will no doubt be tested and extended in due course, but meanwhile they strengthen the suspicion that eclampsia may one day be recognised as an endocrine disorder.

THE CALCUTTA TROPICAL SCHOOL

Lieut.-Colonel R. N. Chopra's report for 1934 of the Calcutta School of Tropical Medicine records the retirement of several European officers who have served the school well. Lieut.-Colonel H. W. Acton has since died after a long illness, and his death excites the keener regret for the reason that his fertile brain was still young and vigorous. He had been director since 1928, rendering services of equal distinction as teacher, administrator, and research worker. He has left as a legacy to the school the one and only department of medical mycology in India. The imperial serologist, Lieut.-Colonel R. B. Lloyd, has also retired and Dr. Ernest Muir has severed an association of fifteen years long during which his unselfish and painstaking work on leprosy has achieved a large measure of success. His latest work on the leprolin tests has shown it to be of importance in prognosis and treatment. The report contains a running record of special investigation in many directions. The epidemic dropsy which has been so fatal in Bengal and Bihar during this century seems to be yielding up its secret, for a gram-positive spore-forming bacillus, isolated from the stools in many cases, has been found to agglutinate in high dilution with the sera of convalescent patients. Similar organisms have been recovered from diseased rice, and it is more than probable that the toxic products are elaborated mainly in the rice or in the presence of rice. In Colonel Chopra's department a further study has been made of carbarsone,[1] an organic arsenical preparation which is non-toxic and renders the stools free from amœbæ in three to four days. A similar drug prepared in India and called amibiarson has given almost as good results in 40 cases,[2] the ratio of probable cures to failures being 5 to 1. The action of atebrin on monkeys infected with malaria has been further studied and some light on the transmission of kala-azar has been thrown by the observation that hamsters infected through the bite of the sandfly may not show evidence of infection for eighteen months or more. There is a wide demand from hospitals in Calcutta for various bacteriophages prepared in the school; the perplexing thing about choleraphage is that one year it may agglutinate most of the strains of vibrio isolated and another year may not. It seems that her the cholera vibrio or bacteriophage must be educated" to act one upon the other, and its true lue awaits the next epidemic season. The report a milestone in the progress of tropical research hich can be obtained gratis from the superintendent the Government Press at Alipore, Bengal.

THE PROGRESS OF CREMATION

It is now just fifty years since the first public ematorium in this country was opened at Woking, rgely owing to the enthusiasm of Sir Henry Thomp- n who acquired in 1878 the ground on which it ands. There are now 28 crematoria in this country. uring the year 1934 the municipalities of Birken- ad, Newcastle-on-Tyne, Plymouth, and Stockport pened their own crematoria, Blackpool has since ne the same, while Kent has acquired a suitable te of twelve acres at Charing. But progress is ow and the total number of cremations during 1934 as only 8337, an increase of 866 on the previous ear. An important new move has now been made y the Cremation Society which obtained legal thority on July 8th last to conduct the business industrial assurance. In Sweden, Czecho-Slovakia, nd Germany, where cremation is more popular an it yet is here, a scheme of insurance has helped create a cremation-mindedness among the com- munity. Following this example a small weekly ontribution over a period of years will qualify for ssociate membership of the society with the right cremation at death anywhere in Great Britain. he weekly contribution is only 4*d.* for five years the proposer is under 45, and 3*d.* if he is under 18. n associate may insure further against funeral xpenses up to a maximum of £20. The Cremation ociety is also promoting the formation of a National ouncil for the Disposition of the Dead which has ow come into being and is making its first objective he State registration of undertakers which will ave the way to the revision and codification of he law of burial. The Cremation Society would ke to remove the popular impression that cremation s expensive. Life membership of the society costs ve guineas and covers the cost of cremation at eath at any crematorium in Great Britain. The ddress of the society is 23, Nottingham-place, ondon, W.1.

DANGEROUS DRUGS TRAFFIC AT HOME

The annual report of H.M. Government to the eague of Nations for the year 1934 on the traffic in pium and other dangerous drugs deals with the uestion from a national rather than an international oint of view. It is accordingly largely negative in nuch that it has to relate. No opium, coca, or ndian hemp are cultivated in Great Britain or Northern Ireland. There has been nothing new in egislation or administration nor any official publica- ion during the year under review, except that a ranch of the Home Office has been set up to deal with all matters relating to dangerous drugs. It is again reiterated that addiction to narcotics is not prevalent in the United Kingdom, no difficulty has been encountered in applying the Hague and Geneva Conventions, and no important cases of illicit traffic have come to light. The limitation of the internal manufacture of narcotic drugs has been applied in accordance with the Convention of 1931, though some difficulties have been encountered in securing compliance from countries outside the British Empire in regard to requests for the export to their governments of heroin. Five firms only are licensed for the manufacture of medicinal opium in Great Britain, two only for morphine and heroin, both in Scotland, and one for cocaine at Dagenham (Essex). Prepared (or smoking) opium, which is still exported from India and consumed in British colonies in the Far East, is a prohibited possession in this country and its detection punished by heavy fine or imprisonment, while the seized contraband is destroyed. During 1934, 86 persons were proceeded against under the Dangerous Drugs Acts; in the case of 69 convicted 41 were fined, in 13 cases more than £5, and 28 were sentenced to imprisonment, two of them to penal servitude for three years.

Much information may be gleaned from the statistical tables appended to the report. More than 50,000 lb. of raw opium were imported in the year, mostly from Asiatic and European Turkey. The chief import of cocaine was from the Straits Settlements. 28,844 lb. of raw opium were exported, chiefly to the United States. Of morphine, its salts and preparations, 14,317 oz. left this country, chiefly for Canada, Australia, and India; the consignment to China was only 781 oz., or more than 200 oz. less than in 1933. The total exports of heroin were less, 2099 oz. in all, chiefly destined for Australia, Canada, and South Africa. Of cocaine again exports were less than in 1933, Canada, Australia, South Africa, and India being the chief recipients. Of 71,868 oz. of morphine produced in the licensed factories 24,519 oz. were used for conversion into codeine and 12,651 oz. in the preparation of heroin.

CHANGES IN GERMAN CRIMINAL LAW

In Germany criminal law is changing rather rapidly under the Nazi régime with its bent towards racial improvement, and Dr. V. Müller-Hess, who is director of the Berlin Institute for Legal and Social Medicine, has been at pains to set out[1] how these changes are likely to affect medical practitioners. Operations with the patient's consent are legal provided morality is not offended. Abortion is now a criminal offence and anyone advertising or displaying abortifacients to the general public is liable to two years' imprisonment, a provision which does not apply to abortifacient preparations advertised in medical journals. Where a crime is suspected and an operation is considered necessary to verify the facts it may be performed even against the patient's will—e.g., a blood-alcohol test (Widmark) in proof of drunkenness of the driver in a motor accident, curettage in post-abortion or post-partum cases. Where a person is held to be not responsible for a criminal act through insanity or the effects of alcohol or drugs the punishment is mitigated but he is detained in an institution if the public safety demands it. This plea is therefore no longer put forward for the defence as if the prisoner be acquitted it might lead to his detention. As a measure for reducing the number of persons of low moral standard from whom criminals are to a large extent recruited sterilisation is now recommended. Thus a man of 21 years or over can be castrated if his offence shows him to be a dangerous moral criminal; should sexual perversion lead to homicidal risk castration becomes a means of ensuring the public safety. Dr. Müller-Hess and his colleague, Prof. F. Wiethold, admit that to decide whether castration should be done is a difficult and involved problem; many doctors hesitate to give their opinion on this, for like the death sentence it is final. The whole science of sex must, they argue, be brought into consideration as the secretions of ductless glands other than the testes are responsible for the sexual impulse. The excitable and unbridled moral criminal becomes phlegmatic and peaceful after castration—half of those castrated are said to be cured of their criminal inclinations—but the ability for work is diminished. Castration should not be applied to sexual offences committed under the influence of alcohol. Moral offenders, it is believed, stand in great fear of castration, and the new law is acting as a deterrent. The position has been made a little easier for German practitioners by a resolution passed a fortnight ago at the eleventh International Penal and Penitentiary Congress held in Berlin. This resolution called attention to the "favourable preventive-therapeutic results" achieved in cases with a criminal tendency and recommended an amendment of the laws of all countries so as to facilitate castration upon demand or with the consent of the person concerned. This resolution is naturally more binding on the German than on the foreign delegates, who were in a minority, especially as the president of the congress refused a request for voting by nation. Another resolution, which has received less notice in the German press, was passed disapproving the application to the sterilisation of criminals of principles different from those of eugenic sterilisation in general.

HYPOTHALAMIC FUNCTION

OF late years no part of the brain has attracted more attention than the hypothalamus. While it has long been known that stimulation of this part of the nervous system evokes pupillary dilatation, rise of blood pressure and contraction of the bladder, the more precise delimitation of the centres responsible for such reactions has awaited the evolution of a more delicate method of exploration than those formerly employed. Such a method is provided by the Horsley-Clarke apparatus. This is essentially a rigid frame that is fitted to the animal's head and supplied with graduated bars so arranged that the precise site in the brain of a delicate needle-like electrode can be determined. Using this apparatus on cats under Nembutal anæsthesia, Ranson, Kabat, and Morgan[1] have systematically explored the hypothalamic region. They obtained a pronounced sympathetic response on stimulating

> "the lateral part of the hypothalamus in the region occupied by the medial forebrain bundle even up to the edge of the internal capsule. . . . Posteriorly the reactive field is concentrated in a narrow zone dorsolateral to the mammillary body and across the midline in the supramammillary decussation. From this point the reactive column can be traced back into the mesencephalon. We believe that an important pathway descending from the hypothalamus runs caudalward through this region close to the mammillary body and undergoes a partial crossing in the supramammillary decussation."

Stimulation of this area inhibited intestinal peristalsis, and in no part of the hypothalamus could a converse effect be produced. They could get no evidence of a parasympathetic centre in the hypothalamus, and here they differ from J. Beattie who holds that such a function is exerted by the "supra-optic-posterior pituitary-tuber cinereum complex."

Elsewhere Dr. Ranson[2] reports that he and his collaborators have found in addition that lesions placed so as to interrupt the continuity of the hypothalamico-hypophyseal tracts, which pass from the supra-optic nuclei to the posterior lobe of the pituitary, will produce symptoms of diabetes insipidus. But it is essential that the lesions should be bilateral and symmetrical. Post-mortem investigation showed atrophy in both supra-optic nuclei and posterior lobe in all the 10 cats studied. It is noteworthy that these workers were not able to produce the picture of Fröhlich's syndrome by experimental hypothalamic lesions. A further point of interest is their observation that extensive injury to the region of the mammillary bodies causes catalepsy and somnolence. This work is being repeated on monkeys, and it will be interesting to see if similar results should be obtainable in an animal so much more closely related to man.

FOOD STORAGE

THE report[1] of the Food Investigation Board for 1934 deals chiefly with how to preserve foods brought from long distances. The discovery that beef can be stored for 60 to 70 days in a chilled state by enriching the air of the store with carbon dioxide has made it practicable to bring beef to this country from Australia and New Zealand, and the first shipment has arrived here in good condition. The interests of the home producer are being cared for by a further development of gas storage for the preservation of apples; there is now storage capacity for about 400,000 bushels. The herring industry is being promoted by experiments at the Torry Research Station, which have shown that herrings frozen at the usual temperature of minus 5° F. would still make good kippers after at least five months' storage at that temperature. Home-caught fish may thus be available all the year round. Certain kinds of fruit have been found to keep free from mould for a longer period if wrapped in iodised paper; some varieties however resent this treatment. The use of iodised wrappers is accordingly being tested under commercial conditions. Those who retain the juvenile habit of eating apples, peel and all, may claim a scientific warrant for so doing, as it has been found that in Bramley's seedling the vitamin-C content increases as the skin is approached, and is six times as great in the peel as in the core. The vitamin potency of rosy apples is more than twice that of green ones. Apples, it seems, do not lose vitamin potency either on storage or when canned. Experiments on the addition of artificial vitamin C to foods such as runner beans and other vegetables which do not naturally contain it may lead to the production of useful antiscorbutic foods. The report contains much else of interest. To the work of the Board is largely due the varied selection of foods which we now enjoy at all times of year.

THE King has appointed Mr. James Learmonth, regius professor of surgery in the University of Aberdeen, to be one of the honorary surgeons to His Majesty in Scotland, in succession to Sir John Marnoch, who has been appointed an extra surgeon to His Majesty in Scotland.

Dr. M. Abdy Collins, medical superintendent of the Kent County Mental Hospital, Chartham, has been elected president of the Royal Medico-Psychological Association, in succession to Dr. Reginald Worth. He takes office next July when the Association holds its annual meeting at Folkestone.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXVII.—PROGNOSIS OF MALOCCLUSION OF THE TEETH

MALOCCLUSION of the teeth includes a wide variety of conditions differing greatly in their type, their effect on facial appearance, and their causation. Our knowledge of the ætiology of many forms of malocclusion is still conjectural, so that a correct prognosis is often difficult to make. The following factors, among others, must be considered by the dental surgeon undertaking the treatment of malocclusion of the teeth.

(*a*) If the child is seen at an early age, is the malocclusion likely to decrease with the eruption of the permanent teeth or will it become accentuated ?

(*b*) If the malocclusion is associated with habits such as thumb-sucking or some pathological condition like post-nasal obstruction, does the success of the dental treatment depend on the removal of the associated condition ?

(*c*) Where alternative methods of treatment appear possible, can a forecast be made of the results of either ? For practical purposes this involves a decision between retaining all the teeth and making room by expanding the jaws or providing space by extraction of one or more permanent teeth. A sound judgment is here of fundamental importance, for a method of treatment once embarked upon cannot easily be abandoned if the results prove unsatisfactory. If all the teeth are retained and room made by expansion, a subsequent relapse may be irremediable. If teeth are extracted as a means of making space, this method of treatment is equally irrevocable. Furthermore, the treatment may involve several stages differing in their objects, each of which is contingent on the success of the preceding stage. It is desirable, therefore, to be able to forecast the result of each stage as an essential link in the chain of treatment.

(*d*) If the teeth have been brought into satisfactory alignment, will the corrected occlusion remain stable, or is there any risk of relapse ?

Natural History of Malocclusion

In order to be able to answer these questions, even with reserve, it is essential to be familiar with what may be called the natural history of malocclusion : the onset of the various types and the changes in form or degree which may occur during the growth of the jaws and teeth. Generalised forms of malocclusion affecting many teeth and involving an abnormal relationship of the dental arches to each other, are dependent on abnormal bone growth. Modern investigations have shown that the factors responsible occur in early life and that they express themselves in the form of an abnormal dentition correspondingly early. Minor forms of malocclusion affecting a few teeth may be due to purely local factors such as the persistence of some habit ; the presence of supernumerary teeth ; injury of disease of a deciduous tooth affecting its permanent successor, and so forth. But these forms of malocclusion are of lesser importance, and the fact that their cause is obvious makes the prognosis comparatively easy. Limiting consideration to serious types of malocclusion affecting the jaws as a whole, we can divide their progress into five stages.

4–6 *years*.—At about the age of four to five the spacing of the deciduous incisors normally takes place. This is due to bone growth, and it allows room for the eruption of the larger permanent incisors. If this spacing does not occur, although the milk teeth may be evenly aligned, there will be insufficient room for the permanent incisors, and thus a potential irregularity exists. Some bone growth may occur later but more frequently a progressive crowding of the permanent teeth takes place during their eruption. If the milk teeth themselves are crowded, even if the crowding be slight, then a marked degree of irregularity of the successional teeth may confidently be predicted. Malocclusion involving an abnormal arch relationship, such as protrusion or retrusion of the upper or lower jaw, may be present in the deciduous dentition. Such a condition will undoubtedly be perpetuated in the permanent dentition in an aggravated form. Here we have the answer to the first question. Malocclusion, whether actual or potential, in the deciduous dentition if left untreated will not as a rule improve but rather progress with the eruption of the permanent teeth. The condition of open bite (an elliptical gap between the upper and lower incisors) is not uncommon in the deciduous dentition, and is often, though not invariably, associated with thumb-sucking or the use of a dummy comforter. In the permanent dentition this gap tends to disappear, but the associated protrusion of the upper incisors will probably be perpetuated. It cannot be said that the correction of thumb-sucking or mouth-breathing will in itself effect a cure of the associated irregularity of the teeth, but it will remove one of the adverse factors and thus improve the prognosis.

6–9 *years*.—During the eruption of the permanent incisors which takes place between the sixth and ninth years, these teeth must take the place formerly occupied by the smaller milk teeth. If spacing has not occurred a malocclusion faintly foreshadowed in the temporary dentition will become a definite irregularity.

11–12 *years*.—The degree and character of malocclusion affecting the permanent incisors may undergo a change for the worse during the period of eruptive activity of the canines, which normally occurs between the ages of 11 and 12 years. It is probable that the first premolars will be present Thus the canines must erupt into a gap between the incisors and first premolars. If the arch is narrow or there is crowding of the incisors there will not be enough room for the canines. These teeth may be forced outwards to resemble miniature tusks ; alternatively, their development and movement in the bone prior to eruption may cause them to press on the lateral incisors and tilt these teeth outwards.

12–13 *years*.—The active development of the second or twelve-year-old molars exerts a pressure on the end of the arch which may push forward the anterior teeth. Any degree of crowding present may thus be made worse. Sometimes a slight degree of crowding not previously severe enough to warrant treatment may be turned into a positive irregularity by the eruptive force of the second molars. If treatment has been carried out with apparently satisfactory results by means of an expansion appliance, relapse may occur at this stage. If, on the other hand, treatment has not been instituted on the grounds that the previous condition did not warrant intervention, then the most favourable period for commencing treatment has been passed and the chances of producing a satisfactory result will be correspondingly lessened. In deciding how long retention of a corrected occlusion should be maintained, attention must be paid to this factor, and any appliance used for retaining the teeth in place should always be worn until the second molars are well in position.

From 17 *years onwards*.—The time of eruption of the third molars or wisdom teeth is very variable. But from about 17 years they are in active growth and their eruption may occur at any period after this age. It is only recently that the third molars have been recognised as factors in orthodontics. In the past many treated cases have relapsed because of the pressure of the wisdom teeth. Before giving a prognosis on the probable progress of malocclusion or on the permanence of the effect to be anticipated from treatment, radiograms should always be taken to ascertain the presence and position of the wisdom teeth. In estimating the amount of room required to accommodate irregular incisors and canines, the dental surgeon must always remember the increasing pressure from behind, consequent on the development and eruption of both the second and third molars, as a factor of fundamental importance which affects the choice of treatment and the ultimate stability of the results obtainable. Similarly, a slight degree of crowding in a child of ten or twelve with its dentition complete for that age—i.e., with the permanent canines and second molars present—may become a marked irregularity a few years later when the third molars begin to approach their eruptive stage. Failure to recognise this possibility at an age when treatment is possible means that when the malocclusion becomes actual and obvious the child has passed the age when treatment is likely to be effective. On all grounds, therefore, it is of cardinal importance to ascertain the position of the third molars and to take this factor into account in making a prognosis both of the development of malocclusion and the results of orthodontic treatment

Results of Treatment

There are many different forms of malocclusion, but speaking broadly the choice of method resolves itself on a decision to move the misplaced teeth by various types of appliances or else to make room by the extraction of one or more permanent teeth. The problems of prognosis of the results of treatment may conveniently be illustrated by taking three characteristic forms of malocclusion.

1. *Superior protrusion,* where the deformity affects mainly the upper arch, and shows itself by a narrow arch, high palate, and prominent front teeth.
2. *Inferior retrusion,* in which the lower jaw is under-developed, the chin is receding, and there is an associated prominence of the upper incisors.
3. *Inferior protrusion,* in which the lower jaw is over-developed and the upper front teeth lie inside the lower incisors instead of overlapping them.

SUPERIOR PROTRUSION

Here the jaw is narrow; the front teeth slope forwards and the lower lip tends to lie behind them, thus making their prominence worse. The essential element in treatment is to push back the upper incisors and canines. In order to create the necessary space the upper arch must either be expanded by an appliance or else a pair of teeth, usually the first premolars, must be extracted. Both methods have their advocates, but it must be borne in mind that the real crowding in these cases is in the region of the roots of the teeth. Expansion is not really a bodily movement of the teeth, but rather a tilting of the crowns, with a relatively slight degree of movement in the all-important apical region. It is not difficult to push out the crowns by means of an appliance and to obtain what looks like a satisfactory result. But since the treatment rarely stimulates bone growth there is a risk that the teeth, though evenly aligned, may look a size too large for the face. Furthermore, the pressure from behind of the second and third molars, already referred to, may cause relapse in later life. There is a place for the treatment of these cases by expansion, but in my opinion it should be the method of choice only where the amount of room required is small, say 3 to 5 mm. If the space required is greater than this, then extraction of a pair of permanent teeth may give a better and more stable result. The removal of the first premolars allows the canines to fall back into place, and thus permits the retraction of the prominent incisors to be carried out easily. An additional benefit is that a gap is thus created in the chain of pressure from behind due to the development and eruption of the second and third molars, and one of the most potent causes of relapse is obviated. It is often wise to commence by expansion at about the age of 7 or 8, to see how the jaw develops and later on to extract the premolars when the canines are approaching eruption.

INFERIOR RETRUSION

In this condition, which appears to be getting more common, the defect is primarily in the mandible, which is under-developed. The method of choice is to try to bring the lower jaw forwards by means of a plate in the upper jaw, the front of which forms an inclined plane so that when the child bites the lower incisors impinge on the plane and the mandible is thrust forwards. The molars probably erupt more and come into a fresh occlusal relationship, thus stabilising the bite in the new position so that the forward position of the lower jaw, which is thus induced, becomes anatomically fixed. Another method which finds favour with many dentists is intermaxillary traction. This consists of arches fixed to the upper and lower jaws by bands cemented to the molars so that it cannot be removed by the patient. Elastic rings are fixed to the arches so that when the mouth is opened the tension of the elastics tends to pull the upper teeth back and the lower teeth forwards. Prognosis should be guarded. The treatment, though often effective, is to some extent empirical, and in a certain proportion of cases the lower jaw fails to come forwards and though the appearance of the chin is improved so long as the appliance is worn, when it is left out the condition relapses. If treatment is commenced at 8 years, and by the age of 11 years the lower jaw has failed to move forwards, it is improbable that the retrusion of the mandible will be corrected. This does not mean, however, that orthodontic treatment has failed completely. The associated protrusion of the upper incisors, which always exists in this condition, can be treated on the lines already described. There will be a material improvement even though the mandibular retrusion still remains. But while extraction of a pair of maxillary teeth is often an integral part of the treatment, extraction of lower teeth should never be done. Since the lower jaw is developmentally too small it would be a grave error to make it still smaller by the extraction of permanent teeth.

INFERIOR PROTRUSION

This condition is relatively rare. It is often inherited. It is, perhaps, the most difficult of all forms of malocclusion to treat; but in its severe forms it is so marked a deformity that an attempt should always be made to treat it, especially in a girl. The earlier the treatment is commenced the better is the prognosis. While the defect is primarily in the mandible it is not possible to diminish the size of the jaw except by surgical measures, which involve a serious operation. The surgical correction of inferior protrusion has been practised in America by Kazanjian, and in France by Dufourmentel, with satisfactory results. The possibility of utilising this method might be considered in exceptionally severe cases, but it can scarcely be regarded as a normal part of orthodontic treatment at the present time. The essential part of treatment is to push out the upper incisor teeth so that they lie outside the lower incisors, as in the normal jaw. Once this is done the lower incisors will retain the upper ones in place, while the latter will limit the possibility of the lower incisors moving still more forwards and thus increasing the malocclusion. A reduction in size of the lower arch should then be attempted by extraction of an incisor or a pair of premolars combined with the use of an appliance to retract the lower front teeth. The best time to commence treatment is when the upper incisors begin to erupt, for a slight degree of force will then suffice to guide them into a normal alignment. The prognosis is reasonably good both as regards the actual treatment and the liability to relapse and it is usually possible to obtain an improvement, though a restoration to an anatomically normal relationship of the arches is unlikely. In some cases, however, the unknown factor which has led to an over-development of the mandible seems to be progressive, and despite all treatment the condition persists and gets worse. For this reason the prognosis should be cautious.

Orthodontic Appliances

Orthodontic appliances may be divided broadly into *fixed* and *removable* ones. The former cannot be removed by the patient and depend for their retention on bands cemented to various teeth. The latter are like dentures which can be removed at will and are held in place by bands or wires round teeth. Their efficiency depends on a good anchorage and effective leverage. Practically all movements of misplaced teeth can be effected by either fixed or removable appliances provided they are properly constructed. In some cases a fixed appliance is better as affording a more effective application of force to the teeth to be moved. In others, a removable appliance may be preferable; in many cases it may matter little which type is employed. Fixed appliances call for a higher degree of technical skill in their construction and are often more expensive. They are sometimes criticised on the grounds that their presence interferes with the hygiene of the mouth. But if they are properly made, and a reasonable degree of coöperation on the part of the patient can be assured, it is doubtful if a fixed appliance is inherently less cleanly than a removable one.

In complicated cases of malocclusion where movements of individual teeth are required, a fixed appliance, which gives a firm anchorage and allows of an accurate apposition of force to the teeth to be moved, is often better than a plate which is less secure and more liable to move. But fixed appliances are delicate and easily broken, while their repair may be difficult. Since it often happens that children undergoing treatment spend a large part of their life at boarding-schools, the dentist may find it wise to use the simpler method of a removable plate as less likely to be broken, though possibly less mechanically effective. The choice of appliance must always be left to the dental surgeon in charge of the case, for he alone can decide on the method of treatment and adopt the apparatus most likely to bring about the desired result. Provided that the dental surgeon possesses the experience and skill to justify him in undertaking orthodontic treatment, the prognosis should not be materially affected by the particular type of appliance he employs.

Prognosis in Treated Cases

Orthodontic treatment is likely to be tedious; moreover, it involves a considerable interference with a child's life, may clash seriously with its education, and is often costly. Treatment is usually sought because of the ugly appearance of irregular teeth; in a girl the æsthetic defect may attract little attention until adolescence. Then it may be a serious blemish, though at that age little can be hoped from treatment. Early diagnosis is essential and involves recognition of the ultimate progress of the condition if left untreated. The ideal age to commence treatment is about eight, when the permanent dentition is making its appearance and the child is old enough to give the necessary coöperation. The parent has a right to know and the dental surgeon will be expected to say whether there is a good prospect that treatment apparently successful at the age of 12 will remain so in later life. It is not always easy to prophesy, and even the most experienced practitioner may find cases which relapse unaccountably. But the dental surgeon who selects carefully his method of treatment, with due regard to what the various appliances can accomplish and remembers that it is the position of the roots in the bone which matters rather than the crowns of the teeth, should be able to make a reasonably sound prognosis. If he visualises the changes likely to occur during the phases of growth and plans his treatment with the idea that room must be made not merely for those teeth which are irregular, but also for the entire dentition, he will not run the risk of finding a "good" result relapsing through subsequent growth changes. Much orthodontic treatment has failed in the past, and doubtless will continue to fail, because operators have not realised that while it is comparatively easy to move teeth with the delicate but powerful appliances now available, relapse is almost inevitable if there still remains a condition of crowding in that part of the jaws which contains the roots of the teeth.

A. T. PITTS, D.S.O., M.R.C.S., L.D.S.,
Dental Surgeon to the Royal Dental Hospital and Middlesex Hospital.

PEPTIC ULCER OF MECKEL'S DIVERTICULUM

THIS rare cause of severe intestinal hæmorrhage is discussed in a paper by Crols and Van Hasselt in the *Nederlandsch tijdschrift voor geneeskunde* (1935, lxxix., 3637).

Their own patient was a boy aged 3½, and the history was that four days previously he had complained of abdominal pain, which passed off after the bowels had moved. The next day there was another similar attack of pain, followed on this occasion by the passage of a large quantity of dark red blood, and later of a further quantity of tarry blood. On admission to hospital the child was very pale, with a small and rapid pulse. Nothing abnormal was found on abdominal examination except a slightly tender spot to the right of the umbilicus. The rectum was full of blood clot; no polyp or intussusception could be felt. As profuse bleeding continued, immediate operation was performed, and a Meckel's diverticulum, distended with blood, was removed. It was found, on microscopical examination, that the mucous membrane lining the distal part of the diverticulum was of a similar type to that of the fundus of the stomach, including many oxyntic cells. The ulcer from which the bleeding had come was situated in the basal part of the diverticulum—i.e., in the part lined with mucosa of intestinal type. It measured about 4 mm. across, and an open vessel could be seen in the base, which was formed by fibrous tissue infiltrated with round cells, the muscularis having completely disappeared. The patient made a good recovery.

The authors point out that a number of similar cases of ectopic fundus epithelium in Meckel's diverticulum have now been described; they compare the occurrence of a peptic ulcer here to that of a gastrojejunal ulcer after gastro-enterostomy. Cases of hæmorrhage from, or perforation of, the ulcer have been reported, mostly in young children, and almost always in males. The differential diagnosis must be made from intussusception, rectal polyp, and blood diseases such as purpura and the like; in cases with perforation, from acute appendicitis. If, as sometimes happens, perforation is preceded by hæmorrhage, this should suggest the possibility of an ulcer of Meckel's diverticulum. Intussusception is ordinarily seen at an earlier age than the much rarer peptic ulcer of the diverticulum.

WEIL'S DISEASE AMONG COAL-MINERS

IN NORTHUMBERLAND AND DURHAM

BY W. G. A. SWAN, M.B. Durh., M.R.C.P. Lond.

LEPTOSPIRAL infection is probably commoner in the British Isles than might be supposed from the number of cases on record. Since Manson-Bahr's[1] case in 1922 there have been only three satisfactory accounts of outbreaks in this country. Buchanan[2] in 1927 described 31 cases in the Edinburgh area of which 17 were miners. The mortality in his series was 25 per cent. He found virulent leptospiræ in the slime and water in coal-mines and he was able to demonstrate leptospiral infection in about 37 per cent. of wild rats. Hamilton Fairley[3] in 1934 described 2 fatal cases of Weil's disease in London sewer-workers and obtained positive agglutination reactions from 8 other sewer-workers who had suffered from jaundice from seven months to twelve and a half years previously. Davidson[4] and others in 1934 reported a series of 19 cases from Aberdeen, 12 of the patients being fish-workers; the mortality was 31·6 per cent. Halsted[5] described another case in a London sewer-worker and Wolstencroft[6] an isolated case in a canal-worker. Alston and Brown have recently attempted to determine the degree of exposure to risk of sewer-workers and to explore the possibility of prevention by vaccination and other methods.[13]

The best recent account of Weil's disease is that of Schüffner[7] who describes 452 cases from Holland. Most of them occurred in bargemen, fishermen, and slaughterhouse workers; others followed immersion in canals. The mortality in this series was only 10·2 per cent. This low figure is accounted for by the large number of proved cases (60 per cent.) which showed no jaundice and none of which died. The mortality among jaundiced cases was roughly 25 per cent., a figure which is directly comparable with those of the British workers who dealt only with jaundiced cases.

It is generally agreed that leptospiral infection in man is a result of contact with fresh water which has become contaminated by the excreta of infected rats. The portal of entry of the leptospira is probably through small abrasions, and Schüffner[7] from experiments with guinea-pigs showed that the organism has difficulty in penetrating the intact epidermis. He also mentions an epidemic in Lisbon which was spread by drinking water. Man-to-man infection is so rare as to be negligible. Estimates of the carrier-rate for leptospiræ in rats vary. Coles[8] found infection in 9 per cent. of rats from Bournemouth, Foulerton[9] obtained 4 positive results from 101 London rats, while Stevenson[10] also working with London rats found leptospiræ in 30 per cent. Cookson[11] has found leptospiræ in one rat from a Northern colliery in which cases of jaundice had occurred.

The heavy mortality of the more severe form of Weil's disease makes it necessary that more attention should be paid to preventive measures directed against rats and moisture in places where there is danger of incurring infection.

The Present Series

During the last two years we have observed 12 cases of severe jaundice occurring in miners in Northumberland and Durham, in 9 of which we have been able to establish the diagnosis of Weil's disease either by guinea-pig inoculation of blood and urine or by the agglutination reaction which Schüffner[7] considers to be proof positive. Four patients died, giving a mortality of 33 per cent. We have not seen in hospital any cases of Weil's disease without jaundice, but we think it not unreasonable to assume in view of Schüffner's 60 per cent. of unjaundiced cases that many mild attacks of the disease must have escaped notice.

CLINICAL FEATURES

Incubation period.—Schüffner[7] found an average incubation period of 10·3 days. As all our patients were working up to the day of onset and with one exception gave a history of working daily in wet seams it was impossible to determine the date of infection.

Mode of onset.—Lassitude and malaise were present at the onset in all cases. Vomiting occurred in 9 and headache in 7 cases. Abdominal pain was present in 5 and pains in the joints and back in 4. Two patients complained of shivering, 4 were constipated, and 2 had diarrhœa. One patient became deaf and complained of dimness of vision. In one case (No. X.) anuria preceded the appearance of jaundice.

Jaundice appeared 2–9 days after the onset, the average interval being 5 days.

Hæmorrhages.—Except in two cases there was some form of bleeding. (See Table.)

Fever was very variable. Six cases were apyrexial throughout and four of these were fatal. Primary and secondary fever occurred in two cases and in each case the secondary fever was accompanied by rigors. One other case which had no fever on admission exhibited a typical secondary rise while in hospital. Three other cases showed primary fever only. The highest temperature recorded was 103° F.

Renal findings.—A striking feature of three of our cases (Nos. X.–XII.) was a very high blood-urea. Case X. had suppression of urine for 36 hours and in Case XI. there was said to have been some diminution of urinary output before admission. No history of anuria was obtained in Case XII., but the patient passed only 10 oz. of urine in the twenty-four hours between admission and death. In no other case was any diminution of urinary output noted. Albuminuria was present in 10 cases but was heavy in only 6. It is worthy of note that in Cases XI. and XII., which showed very high blood-urea figures, only a trace of albumin was found. For further details the reader is referred to the individual case reports.

Uræmia in Weil's disease has long been recognised on the Continent. Georgopoulos[12] in 1933 reviewed the prevailing opinions on the subject. He quotes the French writers as laying great stress on increased urea-production, but considers that there must be considerable impairment of renal function in addition in spite of the well-known fact that the renal lesions

Lep. = leptospiræ. * g.p. died with jaundice but no leptospiræ found.

in Weil's disease are often comparatively trivial and mainly consist of degenerative changes in the collecting tubules. This view seems to us to be reasonable and is supported in our Cases X. and XII. by definite impairment of water-excretion. In Case XI. at a time when the blood-urea stood at 630 mg. per 100 c.cm. the concentration of urea in the urine was 1·64 per cent.

In no case was there any œdema or rise of blood pressure.

Cerebro-spinal fluid.—In two cases (Nos. IV. and XI.) lumbar puncture was performed and the cerebro-spinal fluid showed, in addition to bile staining, a slight increase in protein and a considerable lymphocytosis. No leptospiræ were found. We have found no record of changes in the cerebro-spinal fluid in the literature of Weil's disease.

CASE RECORDS

I

Colliery A. A. B., aged 27. Admitted July 7th, 1933; discharged August 5th. Eight days before admission he complained of chill, headache, and lassitude. Jaundice appeared on the seventh day and was accompanied by dimness of vision and slight deafness. Also complained of epigastric pain and vomited twice. Worked in damp rat-infested seam.

Admission state.—Temp., 97·9° F.; pulse-rate, 72; intensely jaundiced and drowsy; papular non-hæmorrhagic rash generally; tenderness and rigidity below right control margin; spleen not palpable; blood pressure, 128/78. Urine: specific growth, 1010; acid; bile +; no albumin. Wassermann reaction negative. Van den Bergh reaction: 50 units; direct. Phosphatase: 9·4 units. Fæces: occult blood present.

Progress.—On July 9th there was severe epistaxis. The temperature remained normal until the 17th when there was a secondary rise which lasted until the 25th. Thereafter convalescence was uneventful. Urinary output 70–80 oz. daily.

Bacteriological findings.—No leptospiræ found in urine. Agglutination for *Leptospira icterohæmorrhagiæ* positive up to 1/300 two years after illness.

II

Colliery A. C. D., aged 34. Admitted Nov. 25th, 1933 discharged Jan. 16th, 1934. Three days before admission developed pain in the back and joints, shivering and vomiting. Fellow-worker of A. B. (Case I.).

Admission state.—Temp., 101·6°; pulse, 88; no jaundice on admission, but this appeared on the following day and rapidly deepened to an intense orange yellow; abdomen tender below right costal margin; liver palpable for 1½ in.; no splenomegaly. Urine: sp. g., 1018; acid; bile, +; albumin, +; granular casts. Van den Bergh reaction: 52 units; direct. Phosphatase: 5·5 units.

Progress.—The temperature swung for nine days and then remained normal until Dec. 8th when it was 99°. Next day there was a rigor with severe pain over the liver. The liver was palpable for 2 in. and tender and the temperature was 100·5°. The secondary fever lasted ten days and thereafter convalescence was uneventful. The urine output was from 40–70 oz. daily.

Bacteriological findings.—No leptospiræ in urine. Urine obtained on the nineteenth day of illness failed to produce the disease in two guinea-pigs. Agglutination for *L. icterohæmorrhagiæ* positive up to 1/300 19 months after illness.

III

Colliery A. E. F., aged 26. Admitted Dec. 29th, 1933; discharged Jan. 20th, 1934. Illness began 14 days before admission with weakness, abdominal pain, and vomiting. He had been "working wet" in the pit. In three days jaundice was noticeable. A generalised erythema developed which lasted for 4 or 5 days. No bleeding.

On admission.—Temp., 97·5°; pulse, 110; general condition good; bright golden jaundice; nothing abnormal detected in heart, lungs, or abdomen; blotchy petechial rash over the trunk. Urine: sp. g., 1020; neutral; trace of albumin; bile, ++; no leptospiræ found. Fæces: clay-coloured; occult blood test negative. Van den Bergh reaction: total bilirubin, 22·5 units; direct reaction. Phosphatase: 8·7 units.

Course.—The patient was never seriously ill and there was no fever after admission. Recovery was uneventful.

Bacteriological findings.—Two guinea-pigs were inoculated intraperitoneally with 1 c.cm. of centrifuged urine obtained on Jan. 3rd (nineteenth day of illness). One died on Jan. 15th and the other was ill and was killed. Both showed jaundice, slight hæmorrhages and mottled lungs. Only a few dead leptospiræ were seen on dark-ground examination of material from the liver. A further sample of urine was obtained on Jan. 10th and a guinea-pig inoculated. It became ill and was killed on Jan. 24th. It showed jaundice, hæmorrhages in the intestine, and mottled lungs. Typical active *L. icterohæmorrhagiæ* were present in the liver on dark-ground illumination.

IV

Colliery A. G. H., aged 36. Admitted March 1st, 1934; discharged March 17th. Illness began six days before admission with pain in the neck, which he attributed to water dripping on him in the pit. Jaundice was noted on the following day. There was abdominal discomfort and he vomited several times. There was said to have been blood in the vomitus on one occasion. The bowels became constipated.

Admission state.—Not acutely ill; temp., 98°; pulse, 84; slight jaundice; no rash; nothing abnormal in lungs or heart; slight upper abdominal rigidity. Urine: sp. g., 1020; acid; no albumin; bile, +. Van den Bergh reaction: direct reaction positive; 16 units bilirubin. Cerebro-spinal fluid; bile-stained; total cell count, 136 per c.mm.; lymphocytes, 93 per cent.; polymorphs, 7 per cent.; protein, 0·12 per cent. Wassermann reaction positive.

Course.—There was slight pyrexia up to 101° for the first three days, after which the temperature fell to normal. Recovery was uneventful.

Bacteriological findings.—Blood, urine, and cerebro-spinal fluid all failed to produce illness in guinea-pigs. Agglutination of *L. icterohæmorrhagiæ*. Positive up to 1/300 16 months after illness.

V

Colliery A. J. K., aged 38. Admitted Oct. 27th, 1934; died Oct. 28th. Seven days before admission he complained of faintness and severe headache. Four days later he became jaundiced and vomited blood-stained material. Appetite lost and bowels constipated.

Admission state.—Temp., 97°; pulse, 104; very ill; intense jaundice and generalised petechial hæmorrhages; tongue dry and furred; abdomen tender and liver palpable for three inches. Urine: sp. g., 1015; acid; albumin and bile present. Fæces: occult blood present. Death occurred on the day after admission.

Post-mortem findings (Dr. J. G. Thomson).—Hæmorrhages and necrosis of upper third of rectus abdominis muscle. Lungs: very marked pulmonary œdema and small subpleural hæmorrhages; blood in trachea. Heart: petechiæ in pericardium and endocardium; stomach contained blood-stained fluid and showed four acute ulcers near the pylorus; small acute ulcer in the œsophagus 1½ in. from the cardia; numerous petechiæ and erosions in stomach. Liver: slightly enlarged; no striking lesions present. Kidneys: slightly enlarged; cortex swollen and pale and showed tiny petechial hæmorrhages; mucosa of pelves extremely hæmorrhagic. Intestines: a few petechial hæmorrhages.

Microscopical findings.—Kidney: much hyperæmia; intense cloudy swelling of tubules with debris in their lumen; glomeruli normal but proliferation of Bowman's capsule and debris in the capsular spaces. Liver: very marked cloudy swelling of the parenchyma cells generally with poor nuclear staining but no actual necrosis; the normal lobular structure had disappeared. No leptospiræ were found in Levaditi preparations of liver and kidney.

VI

Colliery C. L. M., aged 52. Admitted Oct. 30th, 1934; died Nov. 6th. Illness began ten days previously with headaches and malaise. Seven days later he became jaundiced. The headaches became less but the jaundice deepened and there appeared in all parts marks like bruises. The appetite became poor. Bowels were very constipated, but the fæces were never pale.

Admission state.—Temp., 97·8°; pulse, 88; general condition poor; drowsy and depressed. Intense orange jaundice; petechial hæmorrhages generalised; large contusion (said to be due to slight accidental blow) over left eye; hæmorrhagic labial herpes, and hæmorrhagic spots on tongue and uvula; tongue red and dry. Abdomen: liver edge extended to three inches below the costal margin; no tenderness or rigidity; spleen not palpable. Urine: sp. g., 1020; acid; albumin and bile present. Fæces: occult blood and bile present. Van den Bergh reaction: serum bilirubin 115 units; phosphatase: 8 units. Bile present in all specimens of urine until death.

Progress.—Patient became steadily worse. On Oct. 31st he passed 72 oz. of urine, and thereafter 10–20 oz. daily. He died on Nov. 6th.

Bacteriological data.—Blood was obtained immediately on admission and inoculated intraperitoneally into two guinea-pigs. Both remained healthy. They were killed and nothing abnormal was demonstrated. No leptospiræ were found in the urine.

Post-mortem findings (Dr. Thomson).—The pleural cavities contained a considerable amount of blood-stained fluid. Trachea and bronchi showed congestion. The right lung had in the upper lobe, posteriorly, two small wedge-shaped areas, each ½ in. in diameter, abutting on the pleura, which suggested recent infarcts. The heart showed extensive fresh hæmorrhages under the endocardium of the papillary muscles. The stomach contained much fluid blood and some small blood clots; petechial erosions numerous, especially near cardia; no gross ulceration. Duodenum normal; bile-ducts patent; pancreas normal. Gall-bladder distended with dark bile; mucosa dark red, suggesting some small hæmorrhages. Liver: slightly enlarged, with smooth capsule; dark olive green on section and friable. Kidneys: both considerably enlarged, weighing 19½ oz.; dark chocolate brown on section and cortex much broadened; glomeruli projected from the cut surface, and some diffuse hæmorrhages could be seen at the junction of cortex and medulla; small pale infarct 6 mm. in diameter in one kidney; pelves of both kidneys distended with blood clot.

Microscopical findings.—Kidney: glomerular tufts not ischæmic; proliferation of Bowman's capsule; tubules showed intense cloudy swelling and round-cell infiltration in places. Infarct in the cortex with an extensive hæmorrhage at its apex. A few hyalinised glomeruli. Liver: bile stasis; moderate cloudy swelling but no necrosis. No spirochætes were found in sections of liver and kidney stained by *Levaditi's method*.

VII

Colliery A. N. O., aged 51. Admitted Feb. 21st, 1935; discharged March 21st. Illness began seven days before admission with feeling of shakiness. Bleeding from nose four days before admission and on two occasions since. Shivered, sweated, and felt weak. Jaundice noticed three days before admission.

Admission state.—Temp., 99°; pulse, 92; bright yellow jaundice; hæmorrhagic labial herpes; tongue dry; no abnormality detected in heart, lungs, or abdomen. Blood pressure 140/70. Blood count: red cells, 3,900,000; hæmoglobin, 80 per cent.; white cells, 19,300 (polymorphs 78 per cent., eosinophils 1 per cent., lymphocytes 19 per cent., monocytes 2 per cent.) Urine: sp. g., 1015; acid; albumin +; bile, +. Fæces: occult blood, ++ on Feb. 25th: negative on March 6th. Van den Bergh reaction: bilirubin 40 units; direct reaction. Phosphatase: 8·2 units.

Progress.—The temperature was very erratic and never went higher than 100°. The urine showed steadily decreasing amounts of bile and albumin and was free from both by March 18th. The jaundice steadily diminished and was scarcely noticeable on discharge. There were no further hæmorrhages after admission.

Bacteriological data.—Blood obtained immediately after admission was inoculated intraperitoneally into two guinea-pigs. Both remained healthy. One was killed on March 5th and no leptospiræ could be demonstrated in any of the organs. Urine obtained on Feb. 22nd (about eleventh day of illness) failed to produce the disease in both the guinea-pigs into which it was injected. Agglutination for *L. icterohæmorrhagiæ* positive up to 1/1000 six months after illness.

VIII

Colliery B. P. Q., aged 36. Admitted April 2nd, 1935; discharged May 13th. Six days before admission he came home from work feeling well. He went to bed and woke up next morning feeling dizzy. He went back to bed and on that day was seized with severe pain especially in head, back, and legs. The pain lasted 2-3 days. On the day of admission he coughed up (?) some clots of blood. The bowels were loose. No jaundice noticed. He had been working as a coal-hewer in a wet part of the pit and his hair showed staining caused by the dye of his cap running, due to water trickling on to his head.

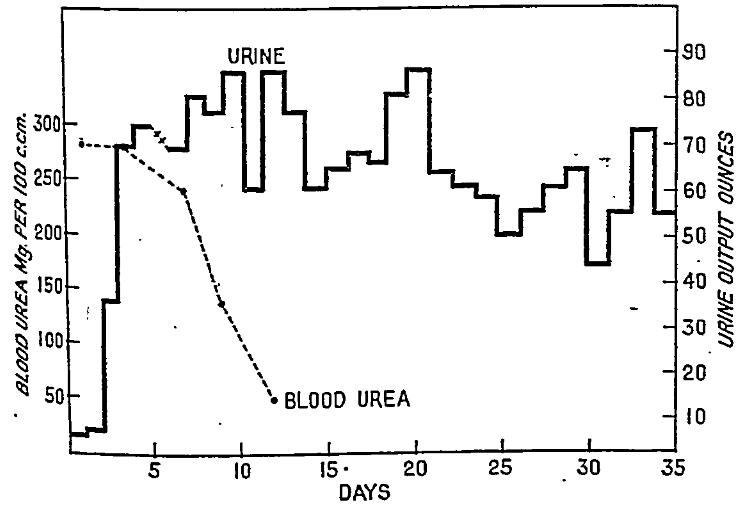

FIG. 1 (Case 10).—Chart of urinary output and blood-urea.

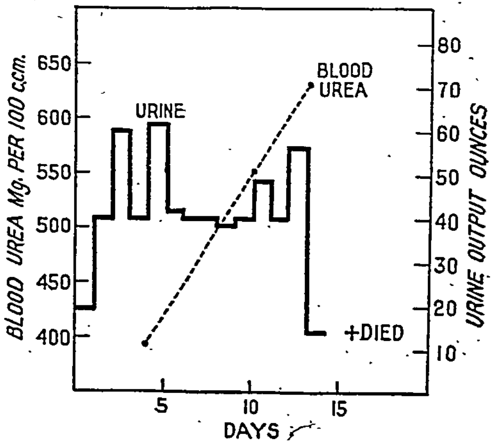

FIG. 2.—Urinary output and blood-urea in Case 11.

Admission state.—Temp., 101°; pulse, 112; very toxic, tongue brown-coated, clots of blood in nares; moderate jaundice; punctate petechial rash over left side of chest and abdomen; no abnormality in heart, lungs, or abdomen. Urine: sp. g., 1020; alkaline; albumin, +; bile, ++. Blood picture: red cells, 3,875,000; hæmoglobin, 84 per cent.; white cells, 10,600 (total neutrophils 95 per cent., lymphocytes 4 per cent., monocytes 1 per cent.). Fæces: occult blood, +. Wassermann reaction negative.

Progress.—At first he became worse. There was severe epistaxis on the day of admission and on the next day. On April 5th there was another severe epistaxis. The jaundice had become deeper. On the 12th he passed a melæna stool. From now onwards he slowly improved, the jaundice gradually faded, and bile and albumin were absent from the urine on discharge. The temperature fell to normal after the first day and never exceeded 99°. The pulse ranged from 70 to 100. When the jaundice had faded he appeared anæmic and a blood count on May 3rd showed red cells, 2,350,000; white cells, 7000; and hæmoglobin, 62 per cent.

Bacteriological findings.—Blood was taken on the day of admission (sixth day of illness) and two guinea-pigs were injected intraperitoneally, No. 1 receiving 2 c.cm. and No. 2 1 c.cm. of blood. No. 1 died 11 days, and No. 2 12 days later. Both animals were wasted and jaundiced. There were subcutaneous and peritoneal hæmorrhages and the lungs showed numerous hæmorrhages. Leptospiræ were present in the liver and kidneys of both animals. Urine was obtained on the thirteenth day of the illness and 2 c.cm. were injected intraperitoneally into a guinea-pig. It died 13 days later. The changes were similar to those in the animals injected with blood and leptospiræ were demonstrable.

IX

Colliery B. R. S., aged 29. Admitted May 2nd, 1935; discharged July 18th. Seven days before admission he complained of general malaise, severe headache, and sweating. Three days later he began to vomit and became jaundiced. The vomit was bright red. Epistaxis began on the third day. Bowels were not opened for five days. Pain in back of legs.

Admission state.—Temp., 99°; pulse, 100; ill and listless; moderate jaundice; blood pressure, 100/70; tongue coated; blood clots in nares; nothing abnormal in heart or lungs. Abdomen distended; tenderness in right hypochondrium; spleen not palpable. Urine: trace of albumin; bile, +; a few pus cells and red blood-cells; no casts. Blood-urea: 85 mg. per 100 c.cm. (June 24th). Fæces: occult blood ++ twice.

Progress.—For the first week he remained rather ill. The temperature reached 101°. There was further slight epistaxis. During the second to the seventh week improvement was slow with occasional evening pyrexia. The liver became palpable and felt hard. The jaundice became much fainter but never quite disappeared. On June 14th the temperature rose to 101°, but subsided on the next day. On the 18th it rose to 99·5° and the jaundice was more obvious. Antileptospiral serum (10 c.cm.) was given. On the 21st and 24th he had rigors. Circumcorneal injection was noted on the 22nd. Antileptospiral serum was again given on June 22nd, 29th, and on July 6th. The temperature reached normal on June 29th and remained there. Convalescence was uneventful.

Bacteriological findings.—Blood obtained on May 3rd (eighth day) failed to produce the disease in a guinea-pig. Urine obtained on May 9th (fourteenth day) was inoculated intraperitoneally into a guinea-pig. The animal died in two days; there was an icteric tinge of the intestines with slight injection; no mottling of lungs; dark-ground examination of liver for leptospiræ was negative. Another guinea-pig inoculated with an emulsion of liver died the next day. A second specimen of urine obtained during the relapse (June 20th) failed to produce disease in two guinea-pigs. Agglutination for *L. icterohæmorrhagiæ* positive up to 1/1000 on July 18th (two and a half months after onset).

X

Colliery D. T. U., aged 32. Admitted May 27th, 1935; discharged June 29th. Illness began seven days before admission with diarrhœa and dull abdominal pain. The diarrhœa lasted for four days and was followed by complete constipation. Passed very little urine and his doctor found solid albuminuria. For 36 hours before admission had passed no urine. Vomited several times and complained of headache and pain in back. The colliery in which he worked had recently been reopened and was very damp. His clothes were often soaked through. No serious illness previously.

Admission state (May 28th, eighth day).—Temp., 97·5°; pulse, 60; very ill and drowsy; tongue brown and dry, breath urinous; no obvious jaundice; Chvostek's sign positive; blood pressure, 90/70. Nothing abnormal found in heart, lungs, abdomen, or central nervous system. Fundi normal. Urine (3½ oz.) withdrawn by catheter was highly coloured but contained no bile; it was "solid" with albumin and contained numerous red and white blood-cells and granular casts. Blood-urea: 285 mg. per 100 c.cm.

Progress and further investigations.—Next day he was less drowsy. Slight jaundice now present; marked conjunctival injection. Urine passed (4 oz.) still solid with albumin, but now giving a faintly positive Gmelin's test for bile-pigments. Blood pressure 110/80.

On the 30th (tenth day) jaundice was well marked, a general golden yellow; copious epistaxis; 34 oz. of urine passed; albumin, ++. Blood-urea: 280 mg. per 100 c.cm. Van den Bergh: direct positive 18 units. Phosphatase 10·6 units.

On the 31st jaundice was more intense; heavy epistaxis; liver palpable two fingers-breadths; occult blood positive 20 seconds. Blood count: red cells, 3,420,000; hæmoglobin, 67 per cent.; white cells, 13,250 (polymorphs 76 per cent., metamyelocytes 3 per cent., myeloblasts 1 per cent., lymphocytes 14 per cent., monocytes 4 per cent., eosinophils 2 per cent.). Antileptospiral serum (10 c.cm.) given intravenously. Patient passed 74 oz. of urine containing only a trace of albumin and moderately bile-stained. From now onwards there was steady improvement. Antileptospiral serum (10 c.cm.) was repeated on June 1st and 4th. The jaundice steadily faded and had disappeared within three weeks from the onset. The urine output never fell below 40 oz. daily and albumin had disappeared on the seventeenth day of illness. The blood-urea fell slowly, being 240 mg. on June 3rd, 135 mg. on the 5th, and 49 mg. on the 8th. At no time did the temperature rise above 99° or the pulse above 90. During convalescence anæmia was noticeable and on June 11th (21 days from onset) the blood picture was: red cells 3,020,000; hæmoglobin, 55 per cent.; white cells, 14,400 (polymorphs 85 per cent.—no immature forms—lymphocytes 12 per cent., monocytes 1 per cent., eosinophils 2 per cent.).

Bacteriological findings.—Guinea-pigs inoculated intraperitoneally with blood obtained on the eighth day of illness and urine obtained during the first and second week remained in perfect health. Agglutination for *L. icterohæmorrhagiæ* positive up to 1/3000 one month from onset.

XI

Colliery A. V. W., aged 56. Admitted June 8th, 1935; died June 24th. Eight days previously illness began with generalised vague pains. On the seventh day abdominal pain commenced, and during the next 24 hours was intense and accompanied by vomiting and hiccup with a tinge of jaundice. The urine had been scanty and bile-stained. Some of the vomit contained blood-stained material.

Admission state.—Temp., 97·8°; pulse, 96; bright orange jaundice; small petechial hæmorrhages over thorax and root of neck; slight itching of the skin; tenderness below the right costal margin, but neither gall-bladder, liver, or spleen palpably enlarged; no rigidity. Blood pressure, 100/56. Urine: sp. g., 1012; acid; bile present; trace of albumin. Fæces: occult blood present. Van den Bergh: direct reaction intense positive; total bilirubin 40 units.

Progress.—On June 10th patient had severe epistaxis and complained of pains in back and legs. Temperature had never been above normal since admission. Testes were painful and extremely tender, but not swollen. Antileptospiral serum (10 c.cm.) given. Next day he was passing very little urine; bowels constipated. Blood-urea: 387 mg. per 100 c.cm. (Fig. 2). Cerebro-spinal fluid: bile-stained fluid under no increase of pressure; colour due to bilirubin, giving direct van den Bergh reaction; protein 0·08 per cent., sugar slightly diminished, chlorides 0·72 per cent., total cell count 64 per c.mm. (all lymphocytes). A further 10 c.cm. serum given and again on the 12th.

On the 14th the jaundice was more intense. More urine was being passed (40–60 oz.), but still intensely bile-stained. Albumin a trace. Complained of pains generally in body and limbs, but especially in the back. Another severe epistaxis. Generalised conjunctival suffusion. Serum (10 c.cm.) was again given. A blood count showed:—

Red cells	3,020,000	Polymorphs	85%
White cells ..	10,625	Lymphocytes	11%
Hb...	63%	Monocytes	3%
Colour-index ..	1	Eosinophils	1%
Reticulocytes ..	1·6%		
Platelets	100,000		

The patient continued to receive 10 c.cm. of antileptospiral serum daily. He was intensely jaundiced and drowsy, passing about 40 oz. of urine per day. Temp., 97°; pulse, 80 (June 17th). Blood pressure, 90/50; blood-urea, 550 mg. per 100 c.cm. On the 18th the urine (40 oz. in all) contained only a little bile; sp. g., 1012; trace of albumin; urea-concentration, 1·62 per cent.; a few leucocytes, no casts seen. Intravenous glucose 200 c.cm. given. On the 19th the liver edge was palpable about an inch below costal margin; spleen not palpable. Blood-urea: 630 mg. per 100 c.cm. On the 21st the blood pressure was 100/60. Urea-concentration 1·64 per cent. Jaundice rather less: no purpura remained. Blood transfusion of 8 oz. given and made up to 10 oz. with 25 per cent. intravenous glucose solution. Antiserum and intravenous glucose continued daily. On June 22nd at 12.30 A.M. the patient was very restless and crying out at intervals. During that day the urea-concentration was 1·58 per cent. in urine. A few red cells and leucocytes were to be seen with granular and epithelial casts. He died on the 24th.

Bacteriological data.—Leptospiræ were found in urine on June 14th. Urine obtained on the 12th (twelfth day) was inoculated intraperitoneally into a guinea-pig and the animal was killed on July 1st. The post-mortem was negative. Blood was inoculated intraperitoneally into a guinea-pig on the 12th and on July 1st it was found that the liver was jaundiced, a few leptospiræ being detected in smears. A portion of liver was inoculated into another guinea-pig on the same day and this animal was killed on July 31st. The findings were: great wasting; a few striated hæmorrhages in lungs; a few infarcts in the kidneys; a few leptospiræ in smears from liver and kidney.

Post-mortem findings (Dr. G. E. Stephenson).—Heart: normal. Lungs: emphysema and chronic bronchitis; some broncho-pneumonia in right upper lobe and recent hæmorrhagic infarct in lower lobe. Spleen: small; no gross abnormality. Liver: average size; dark olive green on section with lobular outline distinct. Gall-bladder contained 1½ oz. light golden yellow bile and debris; no calculi. Kidneys: swollen and soft; capsule thin and stripped easily; surface smooth; cortex swollen and bile-stained; submucosal hæmorrhages in the pelvis. Stomach: numerous submucosal petechial hæmorrhages at fundus and pyloric end. Duodenum and intestines showed no pathological changes. Brain: swollen and œdematous; small subarachnoid hæmorrhage at vertex of right cerebral hemisphere.

Microscopical findings.—Liver: biliary stasis marked; cloudy swelling moderate; no necrosis and no inflammatory cells seen; normal lobular structure well preserved; no leptospiræ found in sections stained by Levaditi's method. Kidneys: much hyperæmia; glomeruli generally healthy though a few showed early sclerotic changes; patches of round-cell infiltration in cortex, and tubules showed well-marked cloudy swelling; no leptospiræ found.

XII

Colliery E. X. Y., aged 46. Admitted June 24th, 1935; died June 25th. Illness began seven days before admission with headache, malaise, and nasal catarrh. Profuse sweating but no pyrexia. Four days later jaundice appeared and quickly deepened. Became delirious and vomited. A hewer in the pit and had "worked wet." There was said to have been another case of jaundice from the same pit.

Admission state.—Temp., 98°; pulse, 96; blood pressure, 90/65; deeply jaundiced; petechiæ scattered over body, most obvious on forearms; circumcorneal injection; Chvostek's sign positive. Heart normal. Lungs: basal râles. Abdomen retracted; liver not palpable. Urine: 10 oz. drawn off by catheter; acid; sp. g., 1019; urea, 1·9 per cent.; trace of albumin; bile, ++; red cells, ++; occasional casts and pus cells. Blood-urea: 567 mg. per 100 c.cm. whole blood. Blood protein: 7·23 mg. per 100 c.cm. serum. Blood calcium: 9·1 mg. per 100 c.cm. serum. Van den Bergh reaction: direct positive; 46 units.

Progress.—Antileptospiral serum (10 c.cm.) given on June 25th. Patient died the same evening.

Bacteriological findings.—Blood was inoculated intraperitoneally into a guinea-pig on June 25th (eighth day). The animal was killed on July 18th; post-mortem negative.

Post-mortem findings (Dr. Stephenson).—Heart: a few subpericardial hæmorrhages; muscle soft and friable; subendocardial hæmorrhages at bases of papillary muscles. Lungs: congestion and œdema; no pneumonia. Spleen: not enlarged; congested. Liver: not enlarged; lobular outline distinct. Gall-bladder: healthy. Left kidney: atrophied, weight 1¼ oz.; capsule thickened and adherent; surface red and granular; cortex greatly atrophied. Right kidney: much enlarged; capsule thin, not adherent; surface smooth; cortex broadened with a few punctate hæmorrhages; hæmorrhages in mucosa of pelvis. Bladder empty.

Microscopical findings.—Right kidney: increased vascularity; glomeruli normal; cloudy swelling in tubules. No leptospiræ found in Levaditi preparations.

Summary

(1) A hitherto unsuspected source of leptospiral infection is present in certain coal-mines in Northumberland and Durham. (2) Twelve cases of Weil's disease among miners are described with a mortality of 33 per cent. (3) There was a history of working in damp rat-infested seams in all except one case. (4) The diagnosis was confirmed by bacteriological examinations in nine cases. (5) Interesting features were very high blood-urea figures in three cases and a lymphocytosis in the cerebro-spinal fluid in two cases.

We wish to thank the honorary medical staff of the Royal Victoria Infirmary and the medical superintendent of the Newcastle General Hospital for permission to publish cases under their care; Dr. H. J. Slade of the bacteriological department of the Royal Victoria Infirmary and the staff of the Durham University College of Medicine bacteriological laboratory for carrying out guinea-pig inoculations; and Major H. C. Brown of the Wellcome Bureau who very kindly performed the agglutination reactions.

INTERNATIONAL PHYSIOLOGICAL CONGRESS

(Concluded from p. 445)

AFTER the official closing of the Congress in Moscow on the afternoon of August 17th the members did not immediately scatter. In the evening they were entertained to a banquet in the Kremlin by the members of the Soviet Government, headed by the President of the Council of People's Commissars, supported by many officers of the Red Army. An opportunity for sightseeing in the Kremlin was unfortunately not offered, and the glimpse afforded at the reception was somewhat tantalising. The hall of St. George in the Great Palace, where the banquet was held, was all of white marble with pillars set into the wall, and must have impressed most of the guests as the most splendid banqueting hall they had ever seen. Outside the great windows the moon showed up the green and golden clustered domes of the cathedrals of the Archangels, of the Assumption, and of the Annunciation.

On the next day many of the Congress members went to a great air display, while others preferred to spend their time in visiting scientific institutions, including especially the Institute of Animal Breeding and the Central Institute of Nutrition. In the former, demonstrations were given of the methods of artificial fertilisation of larger and smaller farm animals, which the Soviet workers have learned and adopted with success. Where the supply of pedigree sires is small and the geographical area to be covered enormous, such a procedure, with distribution by aeroplane, has obviously great advantages—provided that it can be made reasonably successful. Practical use was also being made of production of artificial heat at convenient times, by injection of œstrin, and of diagnosis of pregnancy, especially in mares, with the Aschheim-Zondek reaction.

The Central Institute of Nutrition in Moscow consists of laboratories and a clinic of 125 beds in a separate building. The laboratories are concerned with scientific studies which are mainly in connexion with practical problems of nutrition. Since in Moscow alone 2½ out of the 4½ million people are fed in public dining-rooms, with three hot meals a day, it is obvious that there is plenty to do, if nutrition is to be placed on a sound basis, qualitatively and quantitatively. Particular attention was being paid to the changes which foods undergo in the process of manufacture, to the designing of containers for the distribution of food, and to the devising of flavouring materials which could be prepared on the large scale and which would keep.

Dietary surveys throughout the U.S.S.R. are also undertaken, and Prof. Moltschanowa had recently returned from Tashkend in Central Asia with an incredible amount of luggage, the fruits of a dietary survey, accompanied by a study of the mineral balance and the basal metabolic rate of the people consuming the diets. All the materials collected had to be worked up in Moscow. In the vitamin department Dr. Jarussowa, under Prof. Lavrov, had been engaged on the practical problem of devising a cheap antiscorbutic which could be consumed by people engaged on construction work in labour camps in Siberia, where the ordinary forms of fresh food are difficult to obtain. A potent concentrate has been prepared from spruce needles, which is said to have met the requirement adequately.

In the clinic connected with the Institute of Nutrition patients were selected for purposes of investigation who were suitable for a treatment exclusively dietetic—particularly persons suffering from liver and kidney diseases, from acute rheumatism, from gastro-intestinal diseases, and from some forms of heart disease. Conditions such as gastric ulcer are treated as constitutional rather than local diseases, and the idea seems to be prevalent in the U.S.S.R. that drugs should be avoided wherever possible. The patients seemed to be very well cared for, but it was of course impossible in a single visit to judge of the success of the methods used. This last truth, indeed, applies to the formation of any opinion with regard to the state of social welfare in the whole Soviet Union. Only those who have made more than one visit are competent to report whether progress is being made or not, and it is on the making or not making of progress that a favourable or an unfavourable verdict must be based.

In judging the hospitality of the Government of the U.S.S.R. towards foreign scientists, however, every member of the Congress is an expert, and there is no doubt that the verdict would be completely unanimous. A more delightful welcome has never been offered.

MEDICINE AND THE LAW

Motorist's Consent to Medical Examination

SOME months ago a High Court judge invented a telling method of challenging the medical evidence adduced against motorists who are charged with driving a car while under the influence of drink. He impaled the witness upon the horns of a dilemma. The police surgeon had no right to examine the motorist without the latter's consent: a drunken man cannot give consent. Either, therefore, the motorist was sober because he gave a valid consent to be examined, or else, if he was drunk, his condition could not be described and the prosecution must fail for want of evidence. Alert advocates have naturally made use of this weapon in defence of motorists, for what it may be worth. Thus at the South Western Police-court last month the point was taken by Mr. Laurence Vine on behalf of Mr. R. M. Hutchinson, better known as Harry Tate, the comedian. Dr. R. Anderson, the divisional surgeon, was describing his examination of the accused when Mr. Vine objected that there was no legal right to examine a man who is under the influence of drink. The witness said he had asked the defendant's permission to examine him. "You must have thought," suggested Mr. Vine, "that he was in reasonable possession of his faculties or you would not have asked such an important question about his consent to the examination." The witness replied that he asked the question before he had come to any decision as to Hutchinson's condition. The case, which was remanded, presented no other feature of interest except that the magistrate queried whether it was quite a fair test to ask a man of 63 to stand on one leg—"some elderly people may not be able to stand on one leg, drunk or sober."

When Mr. Justice Rigby Swift first introduced to the public this forensic dilemma about medical examination, the Home Office and the Directorate of Public Prosecutions are believed to have been taken somewhat by surprise. Later the point was viewed with more equanimity. It was a better point under the earlier law when a motorist could be punished for being drunk while in charge of a car than under the present law (Section 15 of the Road Traffic Act, 1930) whereby it is an offence to be merely "under the influence of drink." Magistrates may often find themselves able to decide that a man was not too drunk to have consented to be examined and yet drunk enough to have imperfect control of a car. At common law a drunken person is not incapable of contracting. His contracts are voidable only if he was, at the time and to the other party's knowledge, unable to understand the effect of the transaction. In criminal cases the drunkard is said to obtain no privilege from his condition; he has voluntarily abandoned control of himself and, in Sir E. Coke's words, "what hurt or ill soever he doeth, his drunkennesse doth aggravate it." The law to-day is unlikely to tolerate an argument which would prevent a medical witness from describing the defendant's condition when that condition is the main element in the alleged offence. The accused would gain little if the police surgeon states "his condition was such that in my opinion he was unable to give consent to medical examination."

The Taking of Fingerprints

If medical examination without the examinee's consent can be regarded as a technical assault, it is akin to the taking of a person's fingerprints without authority. Last week some juvenile offenders were being dealt with by magistrates when a parent protested that his son's fingerprints had been taken, and asked (though without success) that they should be destroyed. It is nowadays forbidden to use the words "conviction" or "sentence" in connexion with a child or young person who is dealt with summarily (Section 59 of the Children and Young Persons Act, 1933), and, if we are no longer to brand juvenile offenders as criminals, the protest was natural. The police, however, may well wish to have some record (if proper power exists to take it) whereby they can check the activities of young persons who get into trouble. It is necessary to use every aid to detect the identity of an offender even if, when brought before the magistrates, the offender suffers no severe penalty. No authority has any power to take persons' fingerprints, unless they consent, without first having such persons committed to prison. It is not quite clear why the boys, in the recent case just mentioned, had been so treated. In prison the procedure is presumably governed by the Prison Rules of 1933. These prescribe that the name, age, height, weight, particular marks, and such other measurements and particulars as may be required are to be recorded when the prisoner is admitted to prison and from time to time afterwards in such manner as may be directed. He may also, "if required for purposes of justice," be photographed on reception and subsequently; but no copy is to be given to any unofficial person. In some countries the taking of fingerprints is allowed full scope for civil purposes; in England there is a fierce prejudice against the process for any but criminals. We do not object to having our births, baptisms, addresses, and marriages recorded but we find it degrading to have our fingerprints registered. Persons found wandering and suffering from supposed loss of memory cause endless trouble before they are satisfactorily identified; bodies cast up by the sea or found dead elsewhere remain mysteries; innocent persons are arrested and inconvenienced for want of easy proof of their bona fides. In all such cases anxiety and expense are caused because there is no universal system of registering fingerprints. Classification of skin impressions could index the whole human race. In England public opinion tolerates the system for the purpose of criminal records only.

Tetanus after Appendix Operation

An inquest was concluded at Rochester on August 29th upon the death of Miss Alma Leworthy from tetanus. The deceased, aged 32, had undergone an operation for appendicitis in St. Bartholomew's Hospital, Rochester. Dr. Schulenberg, resident surgical officer, described the results of his post-mortem examination. The operation wound, he said, was soundly healed. It was examined for pieces of catgut; only a piece of thread was found; this was kept for culture. Asked by the coroner as to the source of the tetanus germs, the witness stated that the germ must have entered the patient's body while she was in hospital, and the abdominal wound would be the site of infection. He could not say if it was due to the catgut. Instruments and catgut were sterilised; but this was an abdominal operation and tetanus might arise from the intestines. The tetanus germ was found in the intestines of a small proportion of people; it might lie dormant till it entered the system through a wound. The coroner read a report from the pathological department of the Ministry of Health. It stated that there was no evidence of *Bacillus tetani* in the samples of catgut sent by Dr. Schulenberg, but that cultures taken of tissue gave convincing evidence of the existence of such bacilli. The witness observed that the report merely proved that death was due to tetanus; it did not explain the source of infection. A theatre sister described to the coroner the process of sterilisation of catgut at the hospital, as it had been in operation for the last eight years. In summing up, the coroner referred to the possibility of the tetanus germs entering an abdominal operation wound from the intestines, no matter how careful the surgeon might be. He considered that the high reputation of the hospital had not been tarnished. The jury returned a verdict of death from misadventure and exonerated from blame all concerned in the case.

PANEL AND CONTRACT PRACTICE

Extension of Medical Benefit

It is generally agreed that medical benefit under the National Health Insurance Acts, although good so far as it goes, does not go far enough. From that point however two lines of thought diverge. The adherents to the one line of thought say, "let us extend medical benefit to the dependants of insured persons and thus make national health insurance an integral part of the general health services of the country." Those who take the other point of view say, "let us improve medical benefit itself and endeavour to provide specialist services, laboratory services and the like, to those persons who are insured and who are, therefore, paying for it." The National Association of Insurance Committees adheres to the latter view, and in conjunction with the National Conference of Friendly Societies has decided to call a conference for the purpose of discussing an extension of the services at present available to the existing body of insured persons. The medical profession will be represented at the conference, at which will be discussed the provision of expert medical advice and treatment and laboratory services to supplement and render more effective the general practitioner service for insured persons, in the form of an independent scheme organised under the general direction of the Minister of Health as an integral part of medical benefit.

A Revised Clause

The new Medical Benefit Consolidated Regulations are already in proof, and it is expected that they will be issued very shortly. One amendment in the terms of service, which form the first schedule to the regulations, will be of special interest to insurance practitioners. Under the revised Clause 7 (3) an insured person who, having failed to make the practitioner aware of his claim to be entitled to medical benefit, has incurred expenses either by way of payment or by receiving an account, may apply to the insurance committee for an adjustment of the matter. The committee, if satisfied of the applicant's title to benefit and of the bona fides of his application, may, if they think fit, either refund the amount charged and debit the doctor's account or require the withdrawal of the account rendered; in either event they must credit the practitioner with the remuneration to which he would have been entitled if the applicant had been attended by him as a temporary resident. Applications for consideration under this clause must be made by the insured persons within one month at present, and it is by no means in every case that insurance committees accede to the applications. Superior persons who cannot be bothered with the panel, and so on, until they have incurred expense or received an account meet, as a rule, with short shrift at the hands of committees. But there are more worthy cases—e.g., the man who has been out of work for a long time and whose title to sickness benefit has perhaps expired, and who may think (who can blame him?) that his title to medical benefit has also expired; or the woman who has been married and has been transferred to Class "K." It is proposed in future to extend the period of one month to three months, and to make the clause applicable to cases where a bona-fide mistake has been made by a doctor either in charging a fee or in rendering an account, irrespective of whether the patient is, or is not, on his list. Hitherto Clause 7 (3) has not applied in cases where the patient was on the doctor's list and, strictly speaking, in any case where a doctor had charged for treatment rendered to a patient whose name was in fact included in his list the case fell to be dealt with by the medical service subcommittee. Obviously there is here a divided responsibility. It is the applicant's duty to make it clear to the doctor that he is an insured person, but on the other hand the doctor has been supplied by the insurance committee with a list of his patients in the shape of forms of medical record. Cases have frequently arisen in which, there being no suggestion of bad faith on the part of a doctor, insurance committees have turned a blind eye to the potential breach of the terms of service and have adjusted the matter, with the consent of both parties, by debiting the doctor and refunding the amount paid to the insured person. Adherence to the letter of the regulations would have led to quite unnecessary hearings by service subcommittees. The revised clause will give them proper authority for dealing with genuine mistakes in another way, and it will be welcomed alike by doctors and by committees.

An Unsubstantiated Complaint

Practitioners may sometimes have to defend themselves against accusations which have little if any substance in fact, but this aspect of the case may not become apparent until after a protracted hearing, as in the following case recently investigated by the London medical service subcommittee.

An insured woman, 67 years of age, was given by her daughter a dose of furniture polish one evening in mistake for medicine. The doctor, who was already attending her for subacute pleurisy, paid a visit the following morning when the woman complained of severe headache. It was only after leaving the house that he met the daughter in the street and was told of the mishap. Thereupon he returned to the house and issued an order for the patient's admission to hospital, warning the relatives of the possibility of a sudden collapse due to poisoning. He gave instruction that the remainder of the polish should be taken to hospital with the patient in order that its nature might be ascertained. Later in the day the son called and told him that his mother would not go into hospital and that her relatives did not want her to go, adding that he understood the furniture polish was harmless. The doctor, mindful of the possibility of delayed collapse sometimes associated with camphor poisoning, insisted on the patient's removal to hospital, stating that if his instructions were not followed he would not provide further treatment. He did however instruct the son to report during the evening on the patient's condition. No report was made, but three days later the son called and asked the doctor why he had not visited the patient. The doctor reminded him of their conversation, and the following day he sent a note to facilitate the insured person's transference to another doctor, adding the name and address of a doctor with whom he had arranged for treatment to be provided, if desired, by the relatives.

The relatives complained that the doctor had improperly refused to provide treatment for the insured person and that in consequence it was necessary to obtain the services of another doctor. In the view of the medical service subcommittee (which was adopted by the insurance committee) there was no refusal to attend. The doctor saw the patient twice on the morning of Jan. 18th, and did the proper thing in the circumstances when he advised immediate removal to hospital and gave the necessary document to facilitate admission. By refusing to go the patient (and her relatives) took a very grave risk. The other doctor who was called in on Jan. 19th evidently found nothing urgent in the patient's condition as he did not call again on the next day. What the relatives could and should have done was to have gone back to the doctor and told him that the patient had not entered a hospital, and, if her condition necessitated it, asked him again to attend. As they did not do this the committee took the view that the expenditure incurred in obtaining other treatment was neither reasonably nor necessarily incurred and the doctor could not be held liable for it. Subsequently the doctor arranged for a deputy to attend on his behalf, if so desired, pending arrangements for the transfer of the insured person and he gave the necessary facilities for such transfer. The committee saw no reason to criticise his action.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

THE STUDENTS' OLYMPIAD

THE meeting to decide the high-school athletic championship of the world ended here on August 18th. Twenty-eight nations were represented, and in the final results Hungary was first (481 points), Germany second (465), England third (146), Czechoslovakia fourth (102), France fifth (101), and Japan sixth (88). The city of Budapest entertained the competitors at receptions, banquets, and excursions, and the arrangements made for their accommodation were admirable. As it was holiday time it was possible to find quarters for many of them at schools and colleges. Their food was strictly supervised, and as a result no digestive or gastric illness occurred, though the guests took full advantage of the abundance of varied and cheap fruits which were available. One case of enteric fever was reported but as the patient had a high temperature two days after he left Stockholm he must have been infected in Sweden. There was no dysentery and, apart from one fractured wrist, no serious accident.

TWO BUDAPEST DOCTORS FIGHT A DUEL

Two young doctors, both junior dressers in the surgical section of the New St. John's Hospital, disagreed on some professional matter just before preparing for an operation. The disagreement became heated, and finally the disputants so insulted one another that a challenge to a duel was issued and they fought with swords in a well-known Budapest fencing hall. The fight lasted about ten minutes and one of them received a deep cut on his forehead, penetrating to the periosteum, which required 17 stitches.

RESTRICTION OF SALE OF CAUSTIC POTASH

Caustic potash is used by every housewife in Hungary on washing-day and is sold by every grocer in the form of long sticks. This closely resembles the cheapest kind of sweet popular among poor children, and many accidents have thus been caused. During one fortnight no fewer than 18 children between the ages of two and five suffering from caustic poisoning were brought to the New St. John's Hospital. Many cases of suicide and attempted suicide also are due to caustic potash, for every servant girl deceived in love can get hold of it, and they are apt to disregard the fact that the death it brings is a terrible one. The number of such cases has long caused concern. A few years ago the Minister for the Interior issued an order regulating the sale of caustic potash, but this did not seem to remedy the evil. A new Act now come into force is much more strict. It decrees that caustic potash is to be regarded as a poison, and is to be indicated in the pharmacopœia with a cross. When caustic is sold it must have a label marked with a skull and another label on which it is stated that caustic potash is a deadly poison and is to be kept under lock and key, while especial care must be taken that it does not get into the hands of children. Anyone who sells caustic must call the attention of the customer to its dangers every time a purchase is made, even though the customer has already bought the article many times from him. Hitherto shopkeepers selling caustic without a licence or failing to call the customer's attention to its dangers have been guilty only of a misdemeanour. But now, if negligence in this respect leads to accident or suicide, he will be punished for a felony.

DRINK MORE WINE

The production of wine is one of Hungary's most important industries, but restrictions imposed by other countries have reduced exports to such an extent that it is threatened with disaster. The home consumption of wine, despite its low price, has also fallen. In order to give the industry a fillip it has been arranged that the authorities shall supply a daily ration of half a litre of wine to every soldier in the army. The soldiers are glad to promote the interests of the winegrowers in this way.

TAXATION OF THE CHILDLESS

In view of the falling birth-rate of the last ten years the ministerial council has accepted the draft of a Bill for the taxation of bachelors, married couples without children, and married couples with only one child. According to this scheme the income-tax for bachelors will be raised by 25 per cent., for childless couples by 15 per cent., and couples with one child by 10 per cent. Whether this will lead to an increase in the birth-rate is as yet problematical. But since the decrease in the birth-rate is due to the present economic depression it is probable that only a general improvement in the financial conditions and better prospects will make a change.

PARIS

(FROM OUR OWN CORRESPONDENT)

SIGNS OF THE TIMES

ECONOMY is the order of the day here, with increased taxation, decreased style of living, and a general post in the course of which we all do our best to encourage our neighbours to be honest. An example of such vicarious activity in the matter of income-tax has recently come to light. A surgeon attached to a hospital admitting paying patients discovered one day that the inspector of taxes had been scrutinising the entries made in the books of the hospital in order to ascertain from a new angle what were the fees the surgeon was charging his patients. As the books in question contained references to diagnoses, the enterprising inspector exposed himself to a conviction for the violation of professional secrecy—a subject on which French legislation is very emphatic. The incident is, therefore, not likely to recur; but is symptomatic of the present situation. It is proposed to save a quarter of a million francs a year in the budget of Paris—at the expense of the medical profession. This economy is to be effected by the discontinuation of medical certificates testifying to the birth of a child. The *Syndicat des Médecins de la Seine* has decided to reduce the fees charged by its members by 10 per cent. as a spontaneous gesture of solidarity and patriotism. With his rent reduced by 10 per cent. and with corresponding reductions in the cost of his gas, electricity, and coal, the doctor who forgoes a tithe of his professional income in a "gesture of spontaneous patriotism," gains as well as loses in this period of economic upheaval.

ANTIRABIC TREATMENT AT HOME

Dr. P. Remlinger and Dr. J. Bailly,[1] of the Pasteur Institute in Tangiers, whose bacteriological studies have brought them deserved prestige, have attacked the tradition of some 50 years' standing that everyone bitten by a rabid animal should be sent to a Pasteur Institute, however far away it may be, there to be treated for some 15 to 25 days, according to a mystic ritual. During the past ten years there have been signs of revolt against this centralisation of orthodoxy to which Italy, Russia, Portugal, India, and Japan have all conformed. Since 1925 Prof. Puntoni, of the Anti-rabic Institute in Rome, has been distributing a carbolised vaccine to a great number of antirabic dispensaries. His views as to the harmlessness and potency of the virus of rabies treated by carbolic acid have been confirmed in many quarters, and the statistics of decentralised vaccination with a dead vaccine are said to show that it is in no respect inferior to treatment with vaccines prepared by attenuation of the virus at a central Pasteur Institute.

THE HISTIDINE TREATMENT OF GASTRO-DUODENAL ULCERATION

Prof. Emile Aron, of the medical faculty of Tours, has for some time been studying the effect of daily injections of histidine on the experimental gastroduodenal ulceration in dogs. Since Jan. 1st, 1933, he has also treated some three score human patients in like manner and with results as encouraging as those recently published by Dr. E. Bulmer.[2] With regard to the rationale, Prof. Aron finds that histidine does not act merely by relieving pain, but also by changing the "anatomical evolution of the lesion." This explanation sounds a trifle vague, and there is more precision in the description given of the technique of the injections and of the results achieved. The latter are the more impressive because most of the patients were treated under ambulatory conditions, with few dietetic restrictions, and with only small doses of atropine to supplement the subcutaneous or intramuscular injections of histidine.

CENTENARY OF DR. MAGNAN

Dr. Valentin Magnan, who died on Sept. 27th, 1916, was born in 1835. To the present generation of psychiatrists in other countries than France he is now little more than a name. Yet, with only two or three exceptions, he did more for practical and clinical psychiatry than any other Frenchman. As a clinician, he was tireless in the detection and correlation of signs and symptoms of mental disease, and by defining certain morbid types he did much to promote both diagnosis and prognosis. The mental hospitals with which his name is associated are the Antiquaille of Lyon, the Bicêtre, the Salpêtrière, and the Sainte-Anne. He was curiously like Pinel in many respects—the same clinical acumen, the same kindly devotion to the happiness of each patient. Though Pinel had already done much to make the treatment of the insane more humane and had achieved immortality as "the man who broke the lunatics' chains," Magnan in his early days found much need for reform. Chains were dispensed with, but not isolation cells nor strait-jackets. Some 8 per cent. of the subjects of delirium tremens are supposed to have died from the effects of mechanical restraint. Magnan's substitute for this strait-jacket was the bed. He put his patients to bed as soon as possible and kept them there until his clinical examinations were completed and the patient had had all the rest the bed could give him. Magnan was, in fact, the apostle of passive restraint and rest in bed. Above all, he created and maintained the tradition that because an asylum happens to be a public institution, it must never be allowed to degenerate into an impersonal machine whose victims feel that human kindness has gone out of their lives.

CORRESPONDENCE

ADHESIVE STRAPPING AND THE PATCH-TEST

To the Editor of THE LANCET

SIR,—Since I adopted the methods of Mr. Frank Romer in 1923 I have used adhesive strapping for the support and immediate function of many thousands of injured joints and muscles, encountered among successive undergraduates in Cambridge. Naturally time and experience have led to modifications in actual technique—e.g., I now use an under-layer of Elastoplast, followed by "interlocking" strapping. The fact remains, however, that I can claim to have applied a vast amount of strapping to the human skin. The annotation in your issue of Aug. 17th (p. 382) rightly divides strapping dermatitis into (1) mechanical, and (2) allergic. It is mainly concerned with the latter variety, the ways of employing the "patch-test," and the possibility of "reaction delayed not only 24–48 hours . . . but for as long as 14 or even 24 days." It therefore appeals for "standard conditions" among different research workers.

Now such lengthy preliminaries may be possible before deciding upon the use of strapping in chronic "gravitational affections of the legs," but where a recent injury demands prompt decision and treatment it is impracticable to embark on prolonged tests. In face of this, it is happily my experience that sensitisation dermatitis is extremely rare in practice, and that its incidence is even less since the introduction of elastoplast. I would go so far as to say that it is almost negligible. With regard to the "mechanical" variety, and taking the ordinary sprained ankle for illustration, it is true that walking "from the word go" may incur trauma by pressure of the creasing on the skin over the antero-inferior aspect of the joint. This however is prevented by daily reapplication for the first few days, as the swelling recedes, and the formation of shifting creases thereby. Opportunity is thus incidentally afforded for inspection of the whole area, and for the early discovery of any allergic tendency.

It would therefore appear that neither the bogy of allergy, nor the academic interest of varied "patch-tests," is commensurate in importance with the enormous saving in sick-wastage after sports injuries, to be gained from the immediate employment of strapping, properly applied. As I have recently written (Camb. Univ. Med. Soc. Mag., June, 1935), "Unnecessary sick-wastage and lasting disabilities, to say nothing of blighted ambitions, result from delayed and obsolete treatment. It is insufficiently realised that, on a less dramatic scale, a severe muscular or ligamentous injury may be as much a surgical emergency as the 'acute abdomen.'"

I am, Sir, yours faithfully,

R. SALISBURY WOODS.

Cambridge, August 26th.

To the Editor of THE LANCET

SIR,—Your annotation raises the question of dermatitis due to adhesive plaster. Some years ago I carried out a small research on the same lines as Schwartz and Peck and came to the same conclusion—viz., that the resinous constituent of the plaster caused the trouble. This constituent is the main variable in the different makes of adhesive plaster, and explains the frequent experience of one make of plaster causing more dermatitis than another.

In my experience in the treatment of ulcers and phlebitis of the legs with Elastoplast, dermatitis takes one of four forms.

1. Prickly heat from retained perspiration in hot weather.
2. Circular patches of dry eczema in the upper part of the leg.
3. A severe eczematous process around the ulcer where it seems that the combined effect of the discharge and the plaster is too much for the skin.
4. An acute allergic process not only affecting the whole leg and causing blisters of the feet, but also producing severe urticaria of face, neck, and forearms. This dermatitis may develop on the first application of the plaster, or may appear after some time owing to sensitisation occurring.

Types 1 and 2 can in most cases be ignored, and the plaster applied more tightly, or in nervous patients the elastoplast applied over a gauze bandage or a thin silk stocking. In type 3 I cover the ulcer and the surrounding skin with strips of Ceraban and then apply elastoplast over this. In type 4 elastoplast must at once be stopped and ceraban used; if then dermatitis persists, ichthopaste bandages; and if it still persists, crude coal tar ointment is applied under the ichthopaste bandages. I have also noticed that all forms of eczema are more likely to develop when the bandages are not applied tightly and evenly.

It must be emphasised that this complication of the treatment of gravitational conditions of the legs is not really serious, and I much regret that some writers have gone so far as to recommend the return to Unna's plaster on account of a rarely occurring complication which can be easily overcome. The application of Unna's plaster is a messy and laborious method of treatment which does not appeal to the busy practitioner or work well in hospital out-patient departments, and it must not be forgotten that Unna's plaster also produces at times a very intractable eczema. After seven years of treating ulcers with elastoplast I remain very satisfied with the results, and I keep constantly under treatment a much larger number of cases than could possibly be handled by any other method.

In superficial phlebitis the good results have to be seen to be believed; the gain to patients in comfort and time, and the expense saved, are such that I do not think the method can be improved upon or should be abandoned because of an occasional case of eczema.—I am, Sir, yours faithfully,

A. DICKSON WRIGHT.

Wimpole-street, W., August 28th.

PROCTALGIA FUGAX

To the Editor of THE LANCET

SIR,—Dr. Thayson in his interesting article states that he has found no mention of the above condition in the Danish, English, French, and American text-books and monographs to which he has access. A careful and accurate description of a condition which appears to be identical with *proctalgia fugax* was published in the *Glasgow Medical Journal* of September, 1917, by Mr. Alex. MacLennan, under the title, "A Short Note on Rectal Crises of Non-tabetic Origin." This article is based upon a considerable experience, and Mr. MacLennan concludes that "the lesion is certainly a neurosis, although it affects persons not of a neurotic temperament and otherwise in sound health." He recommends the use of chloroform vaporoles ♏3 (B.W. & Co.) during the attack.

I have had two such cases under my care, both males. In the first the attacks began at the age of 16, and continued till he entered the Army at age 30. During his four years in the Army the attacks ceased entirely. On his return to civil life they recurred with extreme severity, and interfered seriously with his work as a tram-driver. Examination of the rectum under anæsthesia was negative. The attacks lessened in frequency and severity and disappeared some years ago. The second case was that of a man aged 37, married, with one child 10 years old. He had three attacks in two years. He indulged in coitus interruptus, and since this was stopped, a year ago, he has had no further attack.—I am, Sir, yours faithfully,

Bradford, August 22nd. PETER MCEWAN.

To the Editor of THE LANCET

SIR,—My attention was attracted by Dr. Thaysen's article to a case recently under my care.

The patient is a man, previously fit, who complains that he has lost weight for a few months. He also complains of easy fatiguability, anorexia, nausea, morning cough, and vomiting of mucus. During the last six to nine months he has had three or four attacks of pain just at the top of the anal canal. The pain he describes as gnawing or cramp-like, rising gradually to an unbearable crescendo. During the first attack, which lasted for an hour, he sought in all ways to obtain relief, by walking, defæcation, and the insertion of a finger in the rectum without amelioration or increase of pain. It was only with the adoption of a completely doubled-up squatting position with finger tips touching the floor that relief came. The position of defæcation did not apparently allow sufficient flexion for relief. The patient now aborts every attack in the manner described, so that no attack now lasts as long as the first.

Rectal inspection disclosed only a few very small piles, but on examination with the finger the muscular wall of the anal canal seemed to grasp the finger tightly, and when the finger tip touched the fibres of the levator ani surrounding it the patient said "That is the spot where I get the pain." It seems to me that a cramp of portions of the levator ani causes the symptoms (1) because the pain is analogous in character to muscular cramp elsewhere; (2) because of its tendency to spread and to involve the rest of the muscle, even "into the entire pelvic region"; (3) because it occurs, as in this case, during periods of fatigue; (4) because it is prone to arise in a muscle which has recently been excited—in Dr. Blyth's cases the symptoms followed masturbation; (5) because it appears when the patient is getting warm in bed, as happens with cramps in other parts; (6) because of its relief by stretching during the adoption of the squatting position.

I am, Sir, yours faithfully,

Ilford, Essex, August 28th. R. N. C. SMITH.

To the Editor of THE LANCET

SIR,—About 1904 when working in the pathological laboratory of a hospital the question of temporary pain in the rectum was raised, and at least five of those present were able to discuss the symptoms from personal experience. My brother and I were able to compare notes since both of us had had an attack of sufficient severity to cause loss of consciousness. Neither of us was able to attribute the attacks to any cause, nor were they more frequent when run down than when fresh from a holiday. In my own case about half the attacks followed defæcation before retiring; experience taught me that however pressing the desire to empty the bowel during an attack an attempt would aggravate the pain. The anal sphincter was not in spasm. Local heat was the only treatment which seemed to relieve.

Several of my patients seeking advice for some other trouble have told me that they suffered from this discomfort from time to time. It must be a fairly common complaint. Only three patients have sought my advice for it alone. One was a successful K.C., a very highly strung individual who had to cease appearing in court because he knew that rising to plead would bring on an attack. He could not believe that the pain was not due to a growth, and therefore he asked to be examined with a sigmoidoscope. This was arranged to be done under an anæsthetic at 4 P.M., and shortly before he said to me, "Is this not hard lines? For months I have had no appetite and just to-day at lunch when I was really hungry I was allowed only soup." The only female patient with the complaint had sought advice at many sources. Since the attacks were spoiling her life I advised treatment by suggestion. Although she toured Europe she did not succeed in finding any doctor who was able to hypnotise her.

The object of this letter is to seek information. Many of the subjects who have had these attacks have suffered from migraine. Migraine often ceases as age advances. In my own case the attacks have diminished in frequency and intensity pari passu with those of migraine; this suggests the possibility that it is a manifestation of that complaint. Many medical men have attacks of proctalgia fugax. May I ask them to inform you whether they have migraine too. I am, Sir, yours faithfully,

August 27th. M. C. P.F.

BACTERIOLOGY OF RHEUMATISM

To the Editor of THE LANCET

SIR,—I should be greatly obliged to Prof. Douglas Wilkinson if he would publish the reference to the paper in 1886 in which Mantle "reported the *growth* of a diplococcus from the blood and joint fluid of a child with acute rheumatism." The word "growth" I have put in italics. I knew Dr. Mantle personally, and always gathered from him that he described and illustrated a diplococcus in the blood and advanced the theory that the disease was of microbic origin; important points which were given due credit in "Researches on Rheumatism" (p. 94). We (Poynton and Paine) however thought that in 1899 we first "grew in pure culture," and so isolated the diplococcus in this country. It is my duty, whatever is thought of this diplococcus, to correct in public the statement inferred in our work that we were the first to isolate and grow the diplococcus in this country if 13 years before this Mantle had succeeded.

I am, Sir, yours faithfully,

Bath, August 24th. F. JOHN POYNTON.

CERTIFICATION OF DEATH

To the Editor of THE LANCET

SIR,—Dr. Percy Stocks concludes his analysis (published in your issue of August 17th) by referring to the disappointment of the General Register Office at the failure of the new death certificate to improve definition in certification.

The form of certificate is not beyond criticism, but I wish here to draw attention to one way in which the registrar's desire for accurate information is defeated. Any person, on payment of a small fee, may inspect the supposedly secret certificate at the Registrar's Office, and industrial insurance companies regularly require that death claims should be substantiated by the production of a copy. Frequently a working family is entirely dependent on insurance for the funeral expenses, and find that payment is withheld on the grounds that the certificate includes some conditions which may have existed before the policy was taken out. The fear of this is a constant cause of refusal of consent for autopsy. No medical examination is made before a proposal is accepted, a mere declaration of previous good health being required from persons who are almost wholly ignorant of medical terminology. A practitioner who knows that a morally justifiable claim may be legally defeated on such grounds will be sorely tempted to frame his certificate in such a way as to ensure justice at the expense of statistical accuracy.

A thorough inquiry into the conditions of so-called industrial insurance is, despite existing legislation, designed to protect insured persons from exploitation, highly necessary and long overdue. Benefits are quite disproportionate to the premiums required, overhead costs are scandalously high, and the profits made are considerable. I will give one instance from personal experience of the way in which the less scrupulous companies behave.

> A child's life was insured as a result of canvassing by an agent at a time when the child was temporarily at home "on holiday" from a residential school for children with rheumatic heart disease, a fact well known to the agent. Later, the child died during another attack of acute rheumatism, and the certificate was entered as "Acute rheumatic carditis with previous chronic rheumatic carditis." The insurance company refused payment until the parents consulting me I threated publicity.

Incidentally, I would be obliged if the registrar would indicate how such a death can be accurately fitted into the rigid "due to" clauses of the present certificate.

I am, Sir, yours faithfully,

DUNCAN LEYS.

Birmingham, August 20th.

THE DOSAGE OF ALKALI

To the Editor of THE LANCET

SIR,—In view of the facts published by Dr. Wilfrid Oakley in THE LANCET of July 27th (p. 187) under the heading of Alkalosis arising in Treatment of Peptic Ulcer, it is evident that the giving of alkali in the treatment of peptic ulceration needs close control. The formula of pulvis bismuthi compositus, which is indexed in the Extra Pharmacopœia of Martindale and Westcott (20th edition) under the heading of "MacLean's powder," is given as bismuth carbonate 2, sodium bicarbonate 1, magnesium carbonate (heavy) 2. The dose recommended for the first week is stated to be one teaspoonful six or seven times daily, with a double dose last thing at night, and extra powder during the night if the patient wakes. Thus one ounce of the powder may be given in 24 hours. A second formula (hospital formula) is given as bismuth carbonate 1, sodium bicarbonate 3, magnesium carbonate (heavy) 3, and creta preparata 3. One ounce of the former is equivalent to 47 grammes of alkali reckoned in terms of sodium bicarbonate, and one ounce of the latter (hospital formula) is equivalent to 40·6 grammes of sodium bicarbonate.

In Dr. Oakley's seven cases one that was fatal took an average daily quantity of 22·5 grammes over a period of four days, and another 38·6 grammes of sodium bicarbonate daily for fourteen days. Of the four cases that survived alkalosis the smallest daily intake was 23·4 grammes and the largest 54·8 grammes of sodium bicarbonate. It would seem therefore that the dose of pulvis bismuthi compositus is dangerously large, and that particularly in patients who are anæmic or vomiting anything approaching the dosage recommended should be given with caution.

I wish also to draw attention to Dr. Oakley's observation that five of his seven cases were given alkali in powder form. As he remarks, this allows of the possibility of much larger doses of alkali being taken than prescribed, because of the variation in the size and filling of the spoon used for measuring the dose of powder. On account of the inaccuracy of dosage when alkalis are prescribed in powder form it has always been my practice, and for 15 years my teaching in the out-patient department at St. Bartholomew's Hospital, to prescribe alkali in solution. The prescription that I use contains bismuth carbonate grs. 15, sodium bicarbonate grs. 10, heavy magnesium carbonate grs. 7½. It is given six times in 24 hours. Dr. Oakley tells me that its equivalent in sodium bicarbonate is 13 grammes. This quantity of alkali is the maximum daily intake, and as such is less than two-thirds of the minimum quantity that caused alkalosis in Dr. Oakley's series. During a long experience of the use of this prescription no patient has developed alkalosis while taking it, and it is my opinion that this quantity of alkali, combined with other treatment on well-established lines, is adequate. Dr. Oakley's observations make it clear how greatly the dosage of alkali prescribed for this complaint varies in the different wards of even the same hospital.

I am, Sir, yours faithfully,

GEOFFREY EVANS.

Mansfield-street, W., August 22nd.

SIGNIFICANCE OF PERSISTENT HIGH BLOOD PRESSURE

To the Editor of THE LANCET

SIR,—I am much interested to hear from Dr. Wauchope that she finds no contra-indication to the giving of insulin to diabetics with persistent hypertension. I shall certainly follow her advice in suitable cases. My contention that arterio-sclerotic hypertensives stand insulin badly does not rest on an isolated case. In addition to the one I quoted, I can recall that of an arterio-sclerotic man of 80 with diabetes mellitus complicated by cataract and retinitis who was definitely made worse by even 5-unit doses of insulin twice daily, and several similar experiences have been quoted to me by other doctors. Dr. Lawrence, I believe, goes so far as to say that he regards insulin as a substance toxic to arterio-sclerotic vessels, and I have heard Dr. Charles Miller express a similar view.

It seems to me possible that these cases fall into two groups. First, those with diabetes mellitus who later develop essential hypertension; secondly, those with essential hypertension who subsequently develop glycosuria. I suggest that Dr. Wauchope's cases belong to the first group and mine to the second. Unless (or until) a marked degree of arterio-sclerosis develops, insulin, I agree, should do nothing but good to the former. The diabetes which arises secondary to essential hypertension is, in my experience, relatively mild and responds readily to dieting without the use of insulin. The diet need not be a strictly diabetic one but should aim at reducing the patient's weight. With Dr. Wauchope's remarks about hypoglycæmia I also agree.

I am, Sir, yours faithfully,

L. N. JACKSON.

Crediton, August 27th.

TISSUE EXTRACTS IN THE TREATMENT OF CANCER

To the Editor of THE LANCET

SIR,—I have continued my observations on the treatment of cancer with connective tissue extracts [1] and am able to record further good results obtained in inoperable cases. The hypothesis on which the treatment is based is, briefly, that carcinoma arises through failure of a factor which normally inhibits the overgrowth of cells. This inhibitory factor, it is suggested, is secreted by the connective tissue (whence it is discharged into the lymph) and acts most powerfully in the area where it is produced. Treatment is designed to bring this substance into contact with the cancerous cells, wherever they may be, by its intravenous injection; and any effect it may have should apply to secondary deposits just as much as to the primary growth. Experimental work published by Waterman [2] seemed to have a definite bearing on this theory, and since my report two years ago I have made a clinical trial of the tissue extract he described, subject to the modification that it was prepared from an area and an animal corresponding to that of the primary growth in the patient. The extract obtained, unlike that used previously,[1] is free from coagulable protein and relatively stable, and its active life seems to be about twelve weeks as compared with 7–10 days for the previous extracts.

A fellow worker having informed me of the results of some animal experiments he had carried out in an investigation of the value of iodine therapy in cancerous conditions, I made a clinical test of his preparation and found that it tended to relieve pain and to cause some recession of growth. As there was no antagonism between the two lines of treatment I have employed them in combination.*

With one exception all the 17 cases treated were patients in a public assistance hospital. They were all very severe and far beyond help from surgery or radium. The primary focus showed many variations. In no case was I responsible for the diagnosis, nor were the cases subject to any selection. In 6 cases the imminence of death prevented any hope that indications as to the value of treatment might be secured; of the remaining 11 none failed to show some benefit from treatment. Pain was constantly relieved, and 3 of these patients are now leading almost normal lives.

A group of 3, the only cases of prostatic carcinoma, produced perhaps the most remarkable improvement. They were all patients with suprapubic drainage, and none had passed water per urethram for some time, the periods being nine, five, and three months. In all of them normal micturition was secured by treatment. I regard the following case, admittedly the best, as very striking:—

The patient was a man of 80. In May, 1934, suprapubic drainage had been established for retention of urine due to a carcinoma of the prostate which was described as + +. In July, 1934, the condition had been explored and found to be quite inoperable; the growth had invaded the bladder and nothing was attempted. In January, 1935, he was referred to me for treatment. A daily intramuscular injection of iodine was given and gradually increased from 0·002 to 0·006 mg. Intravenous injections of prostatic extract (1–2 c.cm.) were given at intervals of four days. Within six weeks normal micturition was restored and became regular, and after a further month the suprapubic tube was removed. Three weeks later, early in April, the suprapubic wound healed. The patient was discharged from hospital in July, 1935, and was then reported as having no difficulty in micturition.

Great improvement was also secured in a case of universal rodent ulcer in a woman of 80, the lesions on the face being almost completely healed when treatment was brought to an end. The following case is another that deserves notice:—

Mrs. A., aged 47. Carcinoma of the cervix. She had first noticed a vaginal discharge in December, 1933. I first saw her in October, 1934. She had then been bedridden for fourteen weeks, complaining of severe pain, especially in the left leg, and a very offensive and profuse vaginal discharge. The bladder was distended, reaching nearly to the umbilicus, and per vaginam it was impossible to introduce one finger beyond the obstruction caused by the growth. The cervix could not be reached. Catheterisation yielded 14 oz. of urine plus a further 10 oz. of mucus on associated aspiration.

Treatment was with daily intramuscular injections of iodine up to a dosage of 0·004 mg. and with intravenous uterine extract up to 2·0 c.cm. at intervals of four days. After four weeks the pain and discharge were sufficiently diminished to allow of the patient's getting up. After a further six weeks the bladder was normal in size, pain was quite gone, discharge was negligible, and normal micturition was the rule. Per vaginam four fingers could be introduced and the cervix was readily felt.

Although it is believed—and this view is supported by clinical evidence—that the action of the inhibitory agent is more or less specific to its own area, it does not seem to be entirely inert elsewhere.

I have a patient with a large inoperable carcinoma, of uncertain origin, on the left side of the pelvis. As the primary focus was obscure she was treated with iodine 0·002 mg. intramuscularly each day and intravenous breast extract 1·0 c.cm. at weekly intervals. She had very severe and intractable pain. The abdomen was very tense and there was free fluid in it. She had œdema of both legs and was bedridden. A little œdema now persists in one leg. The patient is doing some gardening and leading an almost normal life. The other leg is quite normal and there is no ascites. Her pain is gone. It is interesting to note that her tumour is only slightly smaller, as checked by an independent consultant.

An important point emerges here however—namely, that the extract appears to exercise its inhibitory effect upon the blood-forming mechanism in some degree. To counteract this, liver cannot be used owing to its carcinogenic property, and accordingly hog's stomach was employed (as Ventriculin, in 10 g. doses daily by mouth) to combat any anæmia that might arise.

Dosage must be governed by the requirements of the particular case. In this series the optimum doses seemed to be up to 0·006 mg. of iodine intramuscularly and up to 2·5 c.cm. of the tissue extract intravenously. As the extract is practically protein-free the dose interval is not of paramount importance, but a period of 4–10 days between injections appeared to be suitable. Within the range of these doses no toxic effects need be apprehended.

I do not suggest that the cancerous condition treated by these means cannot possibly recur, but it should be possible to deal with a recurrence by the measures which were effective against the original tumour. Nor must it be thought that any precipitate claim is being entered as to cure. Amelioration is the rule if the case be not too far advanced. The two factors that militate against improvement seem to be anæmia and a large bulk of growth. It is for the latter reason that the hopeful aspect of treatment in cases of carcinoma of the prostate is emphasised, even though they be inoperable; for here a relatively small bulk of neoplasm will produce urgent symptoms. I am not as yet in a position to apportion the relative values of tissue extract and iodine in treatment.

A FOREIGN BODY IN THE TONSIL

To the Editor of THE LANCET

SIR,—Four days ago I was asked to see a lady who complained of sore throat and thought she could see an ulcer on her left tonsil. On examining her I could see a grey-looking patch, covered with a little yellow exudation, in the upper pole of the left tonsil. It felt hard to the touch. With a pair of forceps I removed a small metallic mass the size of a pea and remarked "it looks like the stopping of a tooth." The patient then stated that in June she had lost a stopping and had been to her dentist, who laughingly had asked her if she had swallowed it. The case would appear to be worth recording for the following reasons: (1) That the stopping should have lodged in the tonsil and got buried in it. Presumably it must have happened while she was asleep. (2) That it should have remained there for over eight weeks. (3) That it should have caused so little local or general disturbance.

I am, Sir, yours faithfully,
W. JAMES SUSMAN.

Henley-on-Thames, August 24th.

PUBLIC HEALTH

Ministry of Health: a Jubilee Survey

THE sixteenth annual report[1] of the Ministry of Health, the last to be drawn up by Sir Arthur Robinson, follows the customary plan, with a special section dealing with public health services in London. In presenting it to the King the Minister, Sir Kingsley Wood, summarises the main developments during the last 25 years in regard to those services which now fall within his province. The creation in 1912 of the scheme of National Health Insurance takes pride of place, both chronologically and because of its importance. The vast expansion of the responsibilities of local authorities and the development of environmental health services (water-supply, housing, town-planning) and personal health services (tuberculosis, maternity and child welfare, general institutional provision, provision for the blind, mental treatment and mental deficiency) are then outlined. Paragraphs follow on public assistance, provision for postgraduate medical education, international health organisations, and advances in medical knowledge. In this connexion the Minister says that close and cordial relations must be maintained between his department and the Medical Research Council and also the medical staff of the public health service, "which has in the past played so great a part in the prevention of disease and must in the future also make a notable and increasing contribution to the general treatment of disease." Good relations, he adds, must also be maintained with the medical profession generally as the first line of defence against disease and disability. All will agree that the establishment and development of closer contacts between the State and the medical profession during the last 25 years are of good omen.

Deaths from Botulism in North London

At the final inquest held on August 23rd by the St. Pancras coroner, Mr. W. Bentley Purchase, the jury found that the three women died from botulism as the result of eating nut meat brawn, but that the man died from natural causes. He was the brother of one of the victims, and had eaten some of the same article of food, but Sir Bernard Spilsbury attributed his death to coronary artery disease. His death followed shortly after seeing his sister die in hospital. But there was, the coroner said, presumably a fourth death from botulism, that of a boy who partook of the same food in the house of one of the victims and had died later at his home outside London. Botulism was not at first suspected in his case, but after the autopsy it was regarded as the probable cause of death. The jury added a rider that under present regulations there was no neglect on the part of the manufacturers of the brawn. The coroner, endorsing this rider, remarked that in the future steps might have to be taken to avoid a recurrence. Dr. P. V. Pritchard, acting M.O.H. for St. Pancras, said that as far as the experimental evidence went it seemed that the infection came from an organism attached to some of the vegetables used in the brawn mixture, but which vegetable they had been unable to discover. For preparing this particular brawn peas and carrots had been freshly brought each morning from Covent Garden. It has been made for 29 years, and no previous case of botulism had been traced to it. In reply to a representative of the London Chamber of Commerce, Dr. Pritchard said he knew of no case of botulism which had occurred from food canned in this country or from canned food imported into this country from elsewhere. The deputy director of the Bristol food research station stated that botulism always existed as a danger, but could be combated by simple means which had been common knowledge in this country for at least twenty years. Britain produced from 150 to 200 million cans a year, and in reply to the coroner's question whether the *Bacillus botulinus* had ever successfully passed through the process and caused damage, he said there had been no instance in this country and none in America when those commercial processes had been carried out. All the British vegetable canners were, he said, using an absolutely safe process. Investigations by the Ministry of Health into the origin of the present cases are not yet completed.

Food Poisoning in East Lancashire

The number of cases of food poisoning reported in or near Nelson, Lancashire (see THE LANCET, July 20th, page 160), amounted in all to 174. Of the 7 deaths 3 occurred in Burnley and 4 in the Nelson area; 3 of the latter on July 4th, the fourth on July 22nd. In this case the illness began at the same time as in the other cases; after autopsy the cause of death was certified as toxic myocarditis attributable to food poisoning. Of the deaths in Burnley the first occurred on July 5th, and in this case there was direct evidence of the consumption of infected food in Nelson on July 1st. The second death occurred on July 16th in the Municipal Hospital, the patient having been removed there from the Nelson area. Bacteriological investigation following post-mortem examination showed *B. aertrycke* to be present, but a definite linking up of this case with the infected food was not established. The third death at Burnley (also in the Municipal Hospital) occurred on July 20th; this patient was removed to the hospital from Nelson and the history of his illness was coincident with the other cases of food poisoning in Nelson. In each of the last three fatal cases the medical evidence showed some preceding depression of health. In all seven a verdict of accidental death was returned.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 24TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1553; diphtheria, 840; enteric fever, 61; acute pneumonia (primary or influenzal), 425; puerperal fever, 43; puerperal pyrexia, 134; cerebro-spinal fever, 13; acute poliomyelitis, 35; acute polio-encephalitis, 3; encephalitis lethargica, 7; dysentery, 21; ophthalmia neonatorum, 84. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 30th was 2525, which included: Scarlet fever, 730; diphtheria, 887; measles, 30; whooping-cough, 416; puerperal fever, 19 mothers (plus 4 babies); encephalitis lethargica, 270; poliomyelitis, 13. At St. Margaret's Hospital there were 23 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 4 (0) from measles, 5 (1) from scarlet fever, 22 (4) from whooping-cough, 19 (3) from diphtheria, 51 (12) from diarrhœa and enteritis under two years, and 9 (0) from influenza. The figures in parentheses are those for London itself.

Deaths from diarrhœa and enteritis were scattered over 26 great towns, the highest numbers being Hull and Liverpool each 4, Gateshead and Sunderland each 3, no other great town more than 2. Birmingham and Newport each reported 3 fatal cases of whooping-cough, Sunderland 2.

The number of stillbirths notified during the week was 268 (corresponding to a rate of 41 per 1000 total births), including 29 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. A. G. Taylor to *President* for course; T. Madill to *Orion* as Squadron M.O.; and C. N. Ratcliffe to *Pembroke* for R.N. Hospital, Chatham.

Surg. Comdr. (Emergency List) G. H. S. Milln removed from Emergency List (non report).

Surg. Lt.-Comdr. M. Barton to be Surg. Comdr.

Surg. Lt.-Comdrs. G. Rorison to *Victory* for R.N.B., and J. Cussen to *Furious*.

Surg. Lts. W. J. M. Sadler to *St. Angelo* for R.N. Hospl., Malta; S. J. Wheeler to *President* for course; and G. S. Thoms to *Victory* for R.N.B.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. R. A. Condon and Surg. Lt. D. R. Hughes to *Victory*.

Proby. Surg. Lt. W. G. Campbell to be Surg. Lt.

Proby. Surg. Lts. (D.) A. C. Fuller and J. Bunyan to be Surg. Lts. (D).

F. J. S. Gowar entered as Proby Surg. Lt.

Proby Surg. Sub-Lt. S. E. Cooke to *Pembroke* for R.N. Hospital, Chatham.

Proby Surg. Sub-Lts. to be Surg. Sub-Lts.: J. B. W. Hayward, P. H. K. Gray, and W. H. Osborn.

ARMY MEDICAL SERVICES

Maj.-Gen. (Supern.) J. W. West, C.B., C.M.G., C.B.E., M.B., M.Ch., late R.A.M.C., having attained the age for retirement, is placed on ret. pay.

Lt.-Col. and Bt.-Col. J. M. Weddell, F.R.C.S., K.H.S., from R.A.M.C., to be Col.

R.A.M. Coll.—Maj.-Gen. (Supern.) J. W. West, C.B., C.M.G., C.B.E., M.B., M.Ch., late R.A.M.C., relinquishes the appt. of Professor of Mil. Surgery and Consulting Surg. to the Army.

Col. J. M. Weddell, F.R.C.S., K.H.S., late R.A.M.C., to be Professor of Mil. Surgery and Consulting Surg. to the Army.

ROYAL ARMY MEDICAL CORPS

Maj. T. O. Thompson to be Lt.-Col.

Maj. H. C. Godding, M.C., is restd. to the estabt.

Short Serv. Commissions.—Lt. (on prob.) D. N. Keys is restd. to the estabt.

SUPPLEMENTARY RESERVE OF OFFICERS

E. T. St. M. Brett to be Lt.

ARMY DENTAL CORPS

The undermentioned are granted temp. commissions in the rank of Lt.: J. H. Sherwen and C. W. Upton.

TERRITORIAL ARMY

Lts. F. S. M. Heggs and T. A. L. Davies to be Capts.

Supernumerary for service with the O.T.C.—Lt. R. W. Rattray resigns his commission.

W. I. C. Morris, M.B., F.R.C.S. Edin. (late Offr. Cadet C.Q.M.S., Edinburgh Univ. Contgt., Sen. Div., O.T.C.), to be Lt. for duty with the Med. Unit of that Contgt., July 2nd, 1935. (Substituted for the notification in the *Gazette* of July 19th, 1935.)

Capt. B. Reid resigns his commn.

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. F. H. Taylor, from Active List, to be Capt.

ROYAL AIR FORCE

Wing Comdrs. T. J. Thomas to R.A.F. Station, Calshot, for duty as Medical Officer.

Flight Lts. C. G. Harold to Medical Training Depôt, Halton, and G. O. Williams to Central Medical Establishment.

RESERVE OF AIR FORCE OFFICERS

L. V. McNabb is granted a commission as Flying Offr. in class DD.

INDIAN MEDICAL SERVICE

The undermentioned officers retire: Maj.-Gens. Sir R. McCarrison, Kt., C.I.E., K.H.P., and H. R. Nutt, M.D., F.R.C.S., K.H.S.

DEATHS IN THE SERVICES

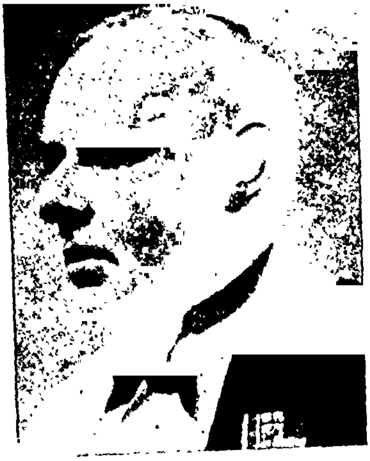
The death occurred on Sept. 1st of Lieut.-Col. James Dorgan, R.A.M.C. (retd.). He was born in County Cork and educated at Clongowes and Queen's College, Cork. He qualified as M.B. R.U.I. in 1898 and entered the R.A.M.C. two years later, becoming major in 1912 when he was stationed at Hong-Kong. He had taken the diplomas of D.P.H. and D.T.M. and early in the war had to deal with a large epidemic of cerebro-spinal fever which gave him the opportunity of investigating the carrier problem. This work was published in our columns (THE LANCET, 1919, ii., 97) when Lieut.-Colonel Dorgan was studying carrier problems in Mesopotamia. His death occurred at Southport where he was living in retirement.

ISOLATION HOSPITALS.—Cheshire county council has prepared a scheme to take over the isolation hospitals in the county which is to be divided into six areas for one hospital. The hospitals would be controlled by a standing committee composed of two-thirds of members of the county council and one-third members of local authorities.

OBITUARY

HUGH WILLIAM ACTON, C.I.E., M.R.C.S. Eng.

THE death of Colonel Acton, briefly announced in our columns last week, deprives the Indian Medical Service of one of its ornaments and tropical medicine of an earnest and successful investigator. It was said of him that he had the ability to look further through a brick wall than anyone else.



[Photograph by Valentine

COLONEL ACTON

Hugh William Acton was born in 1883 in Calcutta where his father owned the Caledonian printing press. He was sent to England for his education, studying medicine at the Middlesex Hospital from which he qualified in 1905. He was house physician there and clinical assistant at the Chelsea Hospital for Women before entering the Indian Medical Service, which he did in July, 1907. He was sent to the frontier to assist Captain J. Woods as medical officer of the 53rd Sikhs at Peshawar, but in 1910 he was given work more congenial to his temperament, becoming assistant director of the Pasteur Institute at Kasauli, then the principal centre for antirabic treatment in India. Still nominally in military employ he was sent to Mesopotamia in May, 1916, and on his release with the rank of major in 1921 he was appointed to the chair of tropical pathology and bacteriology in the newly founded school of tropical medicine at Calcutta. It was then that was revealed the versatility of the man, for during the next 12 years e occupied the chair of helminthology, took charge the department of dermatology, was director of e school for the larger part of the time, and throughout in charge of beds at the Carmichael Hospital. When invalided home from India two years ago it was hoped that he would soon return, but these hopes were disappointed.

The recent annual report by his deputy bears witness to Acton's ability as teacher and demonstrator. He had the gift of clear and precise exposition, with the touch of dogmatism desirable in the instruction of undergraduates, but always with a readiness to give chapter and verse for novel and stimulating views. He was an ideal administrator, knowing from inside what was to be expected from the various departments of the school, and in medical research he had few contemporary rivals. His ability to grasp the essentials of a problem, to map out the lines of investigation, and to coördinate the results were combined with a lively and inquiring mind. His work with Curjel and Dewey on the treatment of tertian fever when in charge of the malarial research laboratory at Dagshai was the first serious work on the action of cinchona alkaloids on malarial parasites, and was followed by further work at the National Institute of Medical Research in which he showed the relation in these alkaloids of chemical formula to optical and therapeutic activity. He demonstrated for instance that the efficacy of cinchona febrifuge depended on the presence of quinidine, and he was successful in tracking down the cause of the toxic effects when quinine is administered intravenously and intramuscularly. His book on the dysenteries of India (1928), written jointly with R. Knowles, sets out advances made in handling these plagues during and since the war. The study filled a real gap, for dysentery has not as yet been the subject of a research expedition such as those organised against kala-azar and plague. More recently his theory of entamœba carriers led to a lively discussion at the Royal Society of Tropical Medicine; Acton held the view that there were two classes of carriers, one with lesions and one without, the former common in India and the tropics, the latter in the temperate zone. This is only to mention a few directions in which his investigations gave practical results; they also covered snake venom, lathyrism, epidemic dropsy, and many aspects of protozoology. His legacy to the school of a department of *mycology* is a reminder of how Acton helped to introduce *order* into one of the most confused subjects *in tropical* medicine.

Sir John Megaw writes: "From the outset Acton's interests lay chiefly in research and at an early stage in his career he collaborated with Colonel Knowles in a brilliant piece of work on snakes and snake venom. This investigation was only the beginning of a long and happy association between Acton and Knowles who remained firm friends as well as colleagues during their long stay at the Calcutta school. Acton's numerous publications testify to his ability as a versatile and original worker, but they do not by any means tell the whole story of his influence on medical research in India. Acton's brain was remarkably prolific in ideas, but most of these were communicated to his colleagues and assistants—to the great benefit of their research work. He was a natural leader of men, and commanded the admiration of his associates to such an extent that their unquestioning acceptance of his views was almost a handicap in his work. His premature death is a heavy blow to his former colleagues and assistants as well as to a large circle of other personal friends."

Colonel Acton married in 1911 May Louise Jacobs and leaves a widow and two sons, one of whom is a medical student.

GEORGE HERBERT MORRISON, M.B. Edin.

Dr. G. H. Morrison, whose death from injuries on August 23rd we annc unced last week, was elder son of the late G. H. Morrison, sometime moderator of the United Free Church of Scotland, and was born in Glasgow in 1898. He received his early education at Glasgow Academy, and as on a cycling tour in Germany when war broke out in August, 1914. He was able *to* reach fri nds in Mecklenburg-Schwerin, at whose house had acted as tutor during the summer vacation, an after the internment regulations came *into force* he w s sent *to* the civilian camp at Ruhleben. There he remained until January, 1918, when after a serious illness he was exchanged and sent home. He was thus 20 ears old when he began to study medicine at Edinburgh University, where his ability and wit made notable as a debater at the *Royal* Medical Societ *and* as editor of the *Student*, the undergraduate weekly. On qualifying in 1923 he joined the editorial staff of THE LANCET for two years; then for a time he returned to clinical work, gaining experience by resident posts at the National Temperance Hospital, and as clinical assistant at the Royal Edinburgh Mental Hospital. After a period of general practice he was appointed medical adviser to Bayer Products Ltd. and editor of "Clinical Excerpts," and in these capacities did much to bring the results of German medical and pharmacological research before the medical profession in this country. Morrison was ready and successful in friendship, and among his wide acquaintance had a well-deserved reputation as a maker of pungent and amusing phrases. His verses were published in *Country Life* and elsewhere, and he was the founder of the King James VI. Society, a flourishing dining-club of Scottish university men. He leaves a widow and a young son.

ANDREW FULLER, L.R.C.P. Edin.

Dr. Andrew Fuller, who died at Perranporth, Cornwall, at the age of 76, was for many years medical inspector for poor-law services under the Local Government Board and Ministry of Health. Born at Codsall in 1859, the son of William M. Fuller, one of the organisers of the Y.M.C.A., Andrew Fuller was educated at Wolverhampton Grammar School and Birmingham University, taking his medical course partly at Queen's College and partly at Edinburgh, from which he qualified in 1882. He was then resident medical assistant at the General Hospital, Birmingham, before entering general practice at Bugbrooke, Northants, which he gave up in 1893 to accept the post at the Local Government Board. Here he was in charge of the care, feeding, and training of pauper children, and of the provision of trained nursing staff for the poor-law service. He was responsible for many improvements in dietary and initiated the systematic medical examination of children in the poor-law schools. He was one of the principal witnesses before the Royal Commission (1909) on the Poor Law, and was associated with Morant in an abortive scheme for coördinating the voluntary and poor-law hospitals. In large measure he deserves credit for the improvement in the character of the hospitals before they became municipalised. During the war Dr. Fuller examined for compensation the victims of air raids, and just before his retirement he was examining the blind for the Home Office. On leaving the public service in 1921 he bought a practice at Perranporth, in which he was joined by Dr. Andrew R. Fuller. Dr. Fuller married Emily Beatrice Lois, daughter of Charles Berry. Another of their sons is Dr. C. B. S. Fuller of Winchester. Mrs. Fuller is a justice of the peace for Cornwall.

Dr. SEAN O'DEA, who died on August 27th, was county medical officer of health for Donegal. A native of County Clare, he qualified M.B. N.U.I. in 1923, and served for a time as a medical officer in the army of the Irish Free State. After taking the D.P.H. in 1926 he spent some time at public health work in England, and five years ago was appointed the first medical officer for Donegal. He had much pioneer work to undertake, but succeeded in laying the foundations of a sound administrative system. In October last he married Dr. Attracta Halpenny, pathologist to the Richmond Hospital, Dublin, and much sympathy is felt for her by a large circle of friends.

MEDICAL NEWS

Society of Apothecaries of London

At recent examinations the following candidates were successful :—

Surgery.—H. N. Davis, Univ. of Oxf. and St. Bart.'s Hosp. ; H. Firman, Univ. of Manch. ; N. R. James, London Hosp. ; E. E. Le Feuvre, St. Mary's Hosp. ; R. A. McMillan, Middlesex Hosp. ; F. R. Neubert, Univ. of Liverp. ; S. E. Osborne, Guy's Hosp. ; and J. E. G. Wright, Queen's, Univ. of Belf., and Westminster Hosp.

Medicine.—E. L. Burgess, King's Coll. Hosp. ; J. A. Carter, Univ. of Camb. and London Hosp. ; E. M. Craggs, Middlesex Hosp. ; H. Firman, Univ. of Manch. ; R. G. Joyce, Welsh National School of Medicine ; H. N. Levitt, Guy's Hosp. ; and F. R. Neubert, Univ. of Liverp.

Forensic Medicine.—E. M. Craggs, Middlesex Hosp. ; H. Firman, Univ. of Manch. ; H. W. John, St. Mary's Hosp. ; and F. R. Neubert, Univ. of Liverp.

Midwifery.—H. N. Davis, Univ. of Oxf. and St. Bart.'s Hosp. ; J. E. Garson, Univ. of Madras and West London Hosp. ; A. Morgan, Univ. of Manch. ; M. A. Partridge, Guy's Hosp. ; and S. Roberts, Univ. of Bristol.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery : E. L. Burgess, J. A. Carter, H. N. Davis, J. E. Garson, R. G. Joyce, H. N. Levitt, S. E. Osborne, S. Roberts, and J. E. G. Wright.

University of Glasgow

Dr. Duncan Blair, professor of anatomy and dean of the medical school at King's College, University of London, has been appointed regius professor of anatomy in the University in succession to Prof. T. H. Bryce, who has resigned.

Duncan MacCallum Blair was born in 1896 and educated at Woodside School, Glasgow, and Glasgow University. From 1915 to 1917 he broke into his medical studies to serve as surgeon sub-lieutenant with the R.N.V.R. and returned to Glasgow to graduate M.B. with honours in 1919. In the same year he became demonstrator of anatomy in the University, later proceeding to London, where he held the John Hunter lectureship in applied anatomy at St. George's Hospital medical school until 1927, when he was appointed to his present post. In 1923 Dr. Blair was awarded the Symington prize. He is the author of the section on arthrology in the 6th edition of Cunningham's Text-book of Anatomy, and has of recent years devoted much attention to the study of neurohistology by means of infra-red photography.

University of Birmingham

In connexion with the opening of the session in October, it has been arranged to hold a series of post-graduate lectures at the General, Queen's, and Children's Hospitals, for old students of the school on Friday and Saturday, Oct. 11th and 12th. Sir Walter Langdon-Brown will give an address on Friday in the medical theatre, Edmund-street, and the annual dinner will be held at the Grand Hotel at 8.15 on the same evening. Further particulars may be had on application to the dean.

London School of Dermatology

The Chesterfield lectures, which constitute a systematic course in dermatology, will be given at 5 P.M. during October and November, and January and February. An examination will be held at the end of the course in March and the Chesterfield medal will be awarded. There will be out-patient clinics daily. Medical practitioners will be welcome as occasional visitors on presentation of their cards. Further particulars may be had from the dean of the school, St. John's Hospital for Diseases of the Skin, Leicester-square, London, W.C.2.

Auxiliary Courses for D.P.H.

A three months' course of lectures and demonstrations on clinical practice and in hospital administration for candidates for the D.P.H. will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W., by Dr. A. Joe, the medical superintendent, on Mondays and Wednesdays at 9.30 A.M. and alternate Saturdays at a time to be arranged, beginning on Monday, Sept. 30th. A similar course will be given at the Brook Hospital, Shooter's Hill, Woolwich, S.E., at the same times by Dr. J. V. Armstrong, the medical superintendent, beginning on Monday, Oct. 7th. Applications should be made to the medical officer of health, London County Council, Public Health Department (Special Hospitals), The County Hall, S.E.1.

Dr. A. M. W. Rae, senior medical officer, has been appointed a member of the executive council of the Gambia and an official member of the legislative council.

Dr. H. Harold Scott, assistant director of the Bureau of Hygiene and Tropical Disease, has been appointed director in succession to Sir Arthur Bagshawe, who has retired.

Typhoid Fever in Belfast

The public health committee of Belfast was summoned at the week-end to consider an outbreak of typhoid fever in the Greencastle area of the city. Forty-one cases have been reported, and it is believed that the epidemic is caused by milk, most of the cases having occurred on a particular milk round.

Coventry and Warwickshire Hospital

The board of management of this hospital has decided to begin at once with the first two sections of their extension scheme at an estimated cost of £86,000. This will provide for 69 and 54 beds for patients and 69 beds for nurses.

Hospitals in Newcastle

The Newcastle-upon-Tyne corporation has undertaken to spend £70,000 on extensions to the hospitals under its jurisdiction. Some institutions in the city are full to overflowing, while others have difficulty in filling beds. It has been suggested that a number of the smaller hospitals should be closed and a large new hospital erected.

C.S.M.M.G. Congress

Several medical men are to address the members' congress of the Chartered Society of Massage and Medical Gymnastics to be held at Harrogate from Sept. 18th to 21st. Dr. W. Edgecombe will speak on the Spa Treatment of Rheumatism, Mr. R. Broomhead, F.R.C.S., will give a lantern lecture on Some American Orthopædic Clinics, Dr. F. W. Eurich will speak on Functional Disorders and Malingering, Dr. W. H. Maxwell Telling on Some Points in the Diagnosis and Treatment of Fibrositis, Dr. W. J. Turrell on Short Wave Therapy, Mr. C. Gordon Erwin will give a lantern lecture on Bone Regeneration, and Mr. Basil Hughes will speak on Surgical Developments in connexion with the Sympathetic Nervous System. The founders' lecture will be delivered by Prof. H. H. Woollard, M.D., on Nerves and Vessels of the Skin. All the lectures will be given in the spa rooms, and the annual dinner will be held at the Grand Hotel on the Friday evening.

Fellowship of Medicine and Post-Graduate Medical Association

A post-graduate course in medicine and surgery for men only will be held at the Westminster Hospital from Sept. 16th to 28th. Other courses during September include a course in chest diseases at the Brompton Hospital (Sept. 23rd to 28th); a special M.R.C.P. class at the Brompton Hospital (twice weekly at 5 P.M., from Sept. 10th to Oct. 4th); a week-end course in ophthalmology at the Royal Westminster Ophthalmic Hospital (Sept. 28th and 29th); a course in proctology at the Gordon Hospital (Sept. 30th to Oct. 5th); evening clinical and pathological class for M.R.C.P. candidates at the National Temperance Hospital (Tuesdays and Thursdays at 8 P.M., Sept. 10th to 26th); and a course on the interpretation of X rays at the Medical Society of London lecture room (Sept. 30th to Oct. 4th, at 5 P.M.). Further courses to be given are dermatology at St. John's Hospital (Sept. 30th to Oct. 31st, afternoons); anatomy and physiology at the Infants Hospital (Mondays, Wednesdays, and Fridays at 8 P.M., from Oct. 7th to Nov. 29th); endocrinology at the National Temperance Hospital (Tuesdays and Thursdays at 8.30 P.M., Oct. 8th to 24th); gynæcology at the Medical Society of London (4 P.M. once weekly, Oct. 10th to Nov. 7th); and fevers at the Park Hospital (Oct. 5th and 6th). Detailed syllabuses can be obtained from the secretary of the Fellowship, 1, Wimpole-street, W. 1. Courses are open only to members.

Out-patients at Ipswich

The East Suffolk and Ipswich Hospital is to have its out-patients' department extended, and an attempt is being made to eliminate the attendance of chronic cases. It is hoped that the development of the appointment system will prevent much waste of time. This system has already been started in the casualty department where each patient is handed a card for subsequent attendances. During an experimental period no patient has had to wait longer than ten minutes.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDIC[illegible] 1, Wimpole-street, W.

MON. [illegible] Sept. 14th.—INFANTS [illegible] .W. Afternoon post-graduate course in infants' diseases.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues. and Thurs., 8 P.M.: Clinical and pathological class.—ROYAL CHEST HOSPITAL, City-road, E.C. Mon., Wed., and Fri., 8 P.M.: Class in heart and lung diseases.

SOCIETIES

PADDINGTON MEDICAL SOCIETY.

TUESDAY, Sept. 10th.—9 P.M. (Great Western Royal Hotel, Paddington), Mr. A. Dickson Wright: Sclerosing Injection Treatment in General Practice.

Appointments

JOHNSON, P. DUNBAR, M.R.C.S. Eng., has been appointed Hon. Anæsthetist to the Buchanan Hospital, St. Leonards-on-Sea.

LANYON, C. B., M.D. Lond., Senior Resident Medical Officer at the Queen's Hospital for Children, London.

SLOT, GERALD, M.D., M.R.C.P. Lond., D.P.H., Hon. Physician to the Buchanan Hospital, St. Leonards-on-Sea.

Medical Referee under the Workmen's Compensation Act, 1925: JAMES LAW FALCONER, M.B., F.R.C.S., of Bolton, for Bolton (Circuit No. 5) and Wigan (Circuit No. 6) County Court Districts.

Births, Marriages, and Deaths

BIRTHS

ANDERSON.—On August 26th, at Glasgow, the wife of Frank E. Anderson, M.B. St. And., Sudan Medical Service, of a son.

BLAUVELT.—On August 24th, at Neville-street, S.W., the wife of Hugh O. Blauvelt, F.R.C.S. Eng., of a daughter.

COLES.—On August [illegible] W., the wife of Bennett Coles, [illegible] of a son.

EVERETT.—On Aug[illegible] the wife of A. D. Everett, F.R.C.S. Eng., of a son.

PAUL.—On August 28th, at Welbeck-street, W., the wife of Saville Paul, M.R.C.S. Eng., of Kingsbury, N.W., of a daughter.

WELDON.—On August 23rd, at a nursing-home, Wexford, the wife of Surg.-Lt. Comdr. S. G. Weldon, M.B. Dub., Royal Navy, of a son.

WILLIAMSON.—On August 27th, at Hythe, the wife of S. T. Williamson, M.R.C.S. Eng., of a daughter.

MARRIAGES

TURNE[illegible]—On August 28th, at St. Augustine's, Ki[illegible] gman Turner, M.R.C.S. Eng., to [illegible] Mr. and Mrs. Arthur Couldrey of Bloomsbury.

DEATHS

MACDONALD.—On August 25th, Alderman George Godfrey Macdonald, M.D. Glasg., J.P., at Crich, near Matlock, aged 74.

MORTON.—On August 26th, at a nursing-home, Shadforth [illegible] M.D. Durh., M.R.C.S. Eng., of Henfield, Sussex [illegible] physician, Croydon General Hospital.

REID.—On Sept. 1st, at St. Helens, James Reid, M.B. Edin.

TAGGART.—On August 29th, 1935, following an accident at her residence "Peel Moat House," Heaton Moor, Stockport, Alice Emily, the dearly loved wife of Dr. J. Scott Taggart, aged 62 years.

WILLS.—On Sept. 1st, at Canterbury, Reginald Graham Wills, M.D. Aberd., aged 71.

WORRALL.—On August 25th, Edward S. Worrall, M.R.C.S. Eng., of Crouch Hill, N.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE MEASUREMENT OF ULTRA-VIOLET RADIATION IN DAYLIGHT

By J. S. Owens, M.D., A.M.I.C.E.

SUPERINTENDENT OF OBSERVATIONS ON ATMOSPHERIC POLLUTION, DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

The growing appreciation by physiologists of the value of ultra-violet radiation and the need for some simple means of measurement has prompted me to devise the apparatus described below. The principle upon which it is based has been tried before in different forms, and usually involves the use of an optical wedge. This admits light to a sensitised paper above which is an opaque plate having a row of small holes, and the amount of light reaching the paper through these holes is graduated by the superimposed wedge or its equivalent. We should thus get, with a bright illumination, a greater number of spots on the paper than with a faint illumination, and the number of spots becomes a measure of the amount of light falling on the apparatus. There are, however, serious difficulties in finding an optical wedge suited for use with ultra-violet light, and several methods which have been tried have failed owing to this. A gelatin wedge could be made which would fulfil the purpose, but unfortunately it is not permanent and varies in its transmission with humidity and so on, while it is not easy to make a number of wedges exactly similar.

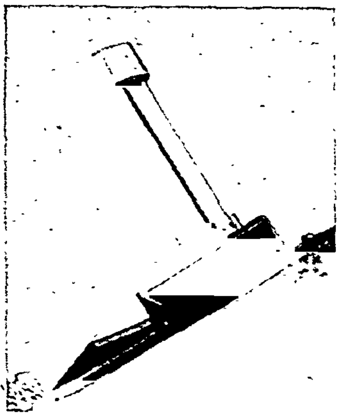


FIG. 1.—Apparatus mounted at an angle of 45°.

THE APPARATUS

The apparatus now described consists of a series of tubes, about ½ in. bore and 6 in. long. These are dead black inside and are arranged in a series of concentric circles. The tubes terminate at the bottom in a plate having a small hole about 3/16 in. diameter in the axis of each. All these holes are the same diameter, and an arrangement similar to an ordinary printing frame permits a piece of sensitised paper to be held close against this perforated plate. The upper ends of these tubes or cells terminate in 13 holes of different diameter, ranging from about 10 mm. down to 0·7 mm.—i.e., from 200 to 1 in area. Over these is placed a piece of ultra-violet glass, such as Chance's No. 14, which transmits nearly all the ultra-violet rays between 3000 and 4000 A.U.

When this apparatus is exposed to daylight, the sensitised paper at the bottom of each cell receives an amount of light which is proportional to the area of the top hole, since all the tubes or cells are the same length. The light received is also inversely proportional to the square of the height of the cell, but this does not affect the present description, since the cells are all the same height. It provides, however, a useful means of adjusting the dimensions, so that the scale of sensitiveness may cover all probable conditions. It is known that the ultra-violet light which reaches the earth is not much, if anything, under 3000 A.U. owing to absorption by the atmosphere, hence there is no advantage in attempting to record wave-lengths below this. The apparatus may be mounted in a vertical position, pointing at the zenith; in this country it does not receive direct sunlight in this position. It is probably better, however, to mount it at an angle of 45° pointing north, as shown in Fig. 1, when comparable results for any country could be obtained.

It is designed for a whole day's exposure, and the scale is such that the brightest and longest day just gives a visible spot under the smallest hole, or perhaps the second smallest hole, while the darkest and shortest day gives a spot under the largest or some smaller hole. After exposure for 24 hours the number of visible spots is noted, not their intensity or darkness, and this number, referred to a scale, gives a measure of the intensity of ultra-violet radiation from the sky.

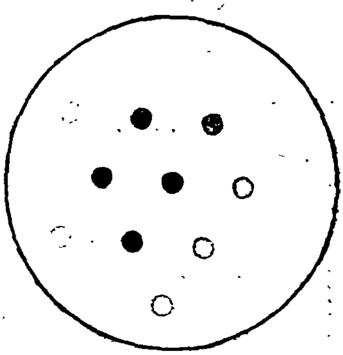

FIG. 2.—Sample record.

A = Cell number. B = Diameter of opening in mm. C = Scale reading based on cell showing just visible spot (paper not fixed).

A	B	C
1	10	1·00
2	9	1·23
3	8	1·56
4	7	2·04
5	6	2·78
6	5	4·00
7	4	6·25
8	3	11·10
9	2·5	16·00
10	2	25·00
11	1·4	51·00
12	1	100·00
13	0·7	204·00

The unit is an arbitrary one—i.e., the amount of ultra-violet light required to give a just visible spot under the cell having the largest top opening. We have, in effect, an optical wedge without any material wedge to vary, the quantity of light received being determined by dimensions alone. No calibration is required, and hence it is easy to make a number of instruments exactly similar. This is important when the instrument is used to compare the amount of ultra-violet radiation received at different places—e.g., in the centre of a smoky city and at the seaside.

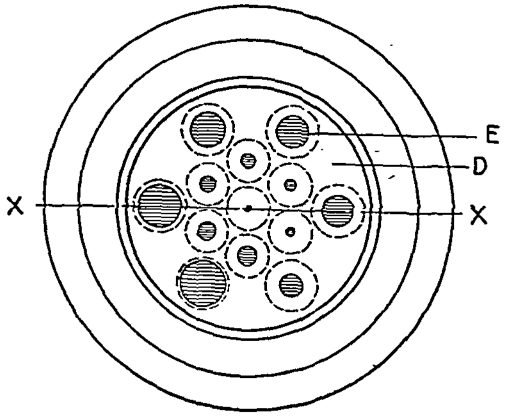

FIG. 3.—General construction of a shorter model: plan with the glass removed.

The sort of record obtained from the instrument is shown in Fig. 2 in which there are 10 spots visible. Reference to the Table gives the amount of ultra-violet radiation as 25. The sensitised paper used is Kodak Kodatone, and I find it preferable to read the record without fixing, which introduces a complication owing to fading, so that the amount of light recorded is only about one-third of that before fixing.

Figs. 3, 4, and 5 show the general construction of the apparatus, but the model is a shorter one than that shown in Fig. 1, and the scale and unit are different. It was found to be too sensitive, hence the length of cells was increased. This shows the simple way in which the sensitivity can be adjusted when fixing the most suitable range for a standard instrument.

THE THEORETICAL BASIS

The basic assumptions in this apparatus are that a paper of sufficiently uniform sensitiveness can be obtained, and that the effect of ultra-violet radiation upon this paper is in proportion to the intensity multiplied by the time of exposure. This last requirement involved checking the effect of what is known by photographers as "reciprocity," or proving that the effect of a uniform light was proportional to the time of exposure. Experiments showed that such an assumption might be made without introducing any important error.

The principle may be summarised in a few words thus. If the sensitised paper requires a definite amount of light to produce a just visible spot, it follows that for the same exposure to different light intensities the area of hole admitting light to the cell under which a just visible spot appears will be inversely as the illumination. Conversely, and since we wish to measure the intensity of the illumination, if we know the area of hole under which a just visible spot appears, after standard exposure, the intensity of illumination will be inversely as the area of this hole. For example, if in one case there is just enough light to make a visible spot under a hole of 50 units area, while in another there is enough to make a spot under a hole of 25 units area, the intensity in the latter case will be double that in the former.

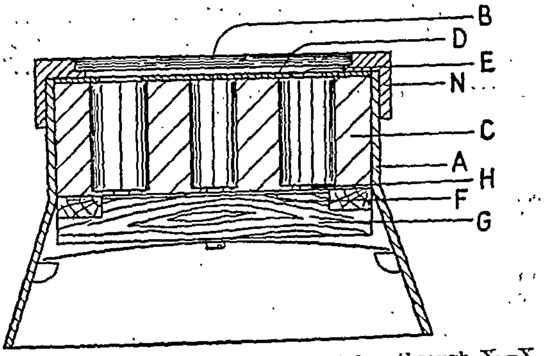

FIG. 4.—Vertical section of the same, taken through X—X in Fig. 3.

A, outer case; B, ultra-violet glass; C, block in which cells are formed; D, top plate showing holes of different diameter; E, hole in top plate over a cell; F, recess for sensitised paper; G, removable pad, as in printing frame; H, hole at bottom of a cell; N, cap for holding ultra-violet glass.

The instrument itself is robust and weatherproof and can be left out in all conditions of weather, the record paper being changed and read each day. It was felt desirable to exclude the effect of direct sunlight and aim at measuring skylight only. Any attempt to include light from the whole sky is subject to the drawback that the result would be governed partly by the area of sky visible from the point of exposure; such an apparatus could not be used amongst buildings where much of the sky is cut off. Experiments made to bring out this point showed that near an obstacle such as a house the light received under an opal dome fell off rapidly. For example, at 10 ft. from a house the reading was 12·5 units, while at 40 ft. it was 17·5. Similarly, near a tree, the reading was 28 units at 10 ft. away, while at 20 ft. it was 37, and at 50 ft. 42. These units are candle power received on the photoelectric cell of a Holophane Edgcumbe auto-photometer, placed under an opal bowl 17 cm. in diameter.

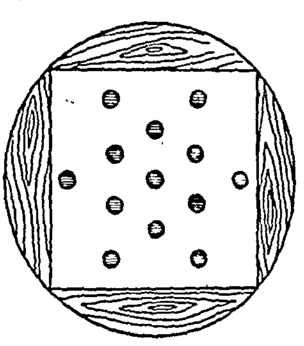

FIG. 5.—Bottom view of block C showing holes H and recess F.

Direct sunlight can be included, if desired, in an instrument exposed to the zenith, by using a diffusing or ground surface on the ultra-violet glass. This will not of course give the whole of the sunshine, but only a fixed proportion. Similarly, a certain amount is lost by reflection from the glass surfaces, but if the proportion so lost is constant for all instruments, it would not affect comparative figures and would be taken account of in any calibration made to find the absolute value of the unit of the apparatus. Such a complication however seemed unnecessary, an arbitrary unit being just as good as an absolute one for the purpose in hand.

An interesting anomaly indicated by observations with this instrument is that the ultra-violet radiation received from the sky is often actually increased by the presence of clouds, which catch and reflect the light from the sun.

RICHARD LOWER AND JOHN MAYOW

Dr. J. F. Fulton, Sterling professor of physiology in the School of Medicine of Yale University, has compiled, with pertinent and learned comment, bibliographies of the writings of the two famous Oxford physiologists, Richard Lower and John Mayow, who flourished in the latter half of the seventeenth century. The work reaches us as a reprint from the proceedings of the Oxford Bibliographical Society, and Dr. Fulton, who has already published through the same medium a bibliography of the works of Robert Boyle, promises to give the same valuable attention to Willis, Hooke, and others who played a prominent part in Oxford science during the Restoration. Oxford scholars and their contemporaries in the seventeenth century were greedy of knowledge, and it emerges from Dr. Fulton's studies that both Lower and Mayow were appreciated in their time, their work being discussed both during their lives and after they had died. Dr. Fulton finds, in accord with the view already expressed by Prof. T. S. Patterson of Glasgow, that Mayow was rather an enthusiastic student, summarising uncritical views held by others and contributing little himself, while Lower was an independent and painstaking investigator.

Lower is well known as the champion of the great Thomas Willis, whose assistant he was. But his treatise on the motion of the heart and the colour of the blood was an original work, as was his proof that the venous blood becomes red on passing through the lungs by virtue of being brought into contact with the air; this was the chief glory of his scientific career, though not his only contribution to learning. The treatise "De Corde" appeared in 1669, was published simultaneously in London and Amsterdam, and between its first issue and 1749 was reissued at least 12 times, while in 1932 it was republished at Oxford. To the second edition of "De Corde" there is an appendix on the origin of catarrh, and Dr. Fulton notes that the references in other literature to this work are usually to the form appended to the "De Corde," while there is evidence that several separate editions of the tractate were published. Lower's other well-known work entitled "Bromographia" is mainly an essay on the use of infusions of barley in medicine. This work appears also to have run through many editions, as issued from various continental, chiefly German, centres, but presumably met with no success in London. The bibliography closes with notes on the many references to Lower and his work occurring in scientific literature or in biographies, and adds an extraordinary elegy dedicated to him. They could certainly in the seventeenth century spread the adulation thickly, for the elegy closes as follows:—

> "And Reader, now wouldst thou his Equal know,
> Go follow him, for there's none left below;
> Go, follow to that Blessed Place Above,
> Where all your Admiration will be Love."

Mayow, whose name sounds the more familiar of the two, owes his fame to his "Tractatus Quinque" which was published after Lower had written "De Corde" and also after the famous experiments of Boyle, Hooke, and others on the respiration had appeared. There seems little doubt that much of Mayow's reputation has been due to the work of others. But Prof. Patterson, while allowing that much of the work on respiration attributed to Mayow was not original, still finds things in the "Tractatus Quinque" which had not been previously described. He points out that Mayow did in an ingenious manner show that what we call hydrogen and nitric oxide expand in the same kind of way as air: that is to say, obey Boyle's Law. And Dr. Fulton finds that Mayow cannot be adequately visualised unless one makes allowances for his youth. When still in his teens he was fired by the new scientific spirit which was abroad in Oxford, and he has left a creditable record of what was going on about him.

It is good to note the close and learned interest which is now being taken in the history of medicine, for undoubtedly the course of medical thought is often directed usefully by knowledge of the theories and exploits, successes and failures of past leaders.

A PILGRIMAGE TO MENTAL HOSPITALS

THIS story of a laywoman's pilgrimage through the mental hospitals of France, Belgium, and Holland[1] provides a useful sidelight on environmental conditions. In the mental hospitals of Belgium visited, most of which are connected with religious nursing orders, Miss Hankin was particularly impressed by the devotion of the nursing sisters and by the attitude of friendliness and affection obtaining between patients and nurses. She noted that confession appeared to play a valuable part as a means of psychotherapy and that many of the priests were trained in human psychology. In Holland, a Lutheran country, where much of the nursing is done by deaconesses, she was also favourably impressed and in both countries, with the notable exception of one institution, she finds much to praise in the hospital conditions. In France, on the other hand, she found both the nursing and the facilities for occupying the patients and developing their individual interests far less satisfactory. It would clearly be unfair to judge of the conditions in any of the three countries from such a brief and limited investigation. It is, however, of interest to observe that Miss Hankin, who has nursed in mental hospitals in England, although not in recent years, notes differences in the attitude adopted to the patients by the nurses, in the provision of suitable occupation, and in the prevalence of red tape. In these respects the foreign hospitals appear to score. In two of the hospitals visited a recovery-rate of 60 per cent. is claimed; whereas in this country this rate is generally considered not to exceed 35 per cent. It would be interesting to know to what extent the figures were based on similar classifications. Miss Hankin was particularly impressed by the colony at Gheel and her regret that we have no parallel in this country is shared by many. She notes also that in certain hospitals where the best results are claimed there is a very high proportion of both nurses and doctors to patients.

NEW PREPARATIONS

MANDELIC ACID (BOOTS).—We have received from Messrs. Boots Pure Drug Company Limited, Nottingham, a sample of their mandelic acid for use in the treatment of urinary infections. This is a crystalline powder readily soluble in water, alcohol, and ether, has a melting point of 118° to 120° C., and is represented by the formula CH(OH).COOH. Two years ago (THE LANCET, 1933, i., 855) Mr. A. T. Fuller, Ph.D., described work performed at the Bernhard Baron Memorial Research Laboratories, Queen Charlotte's Hospital, on the ketogenic diet and the nature of the bactericidal agent concerned. The present use of mandelic acid in the treatment of chronic infections of the urinary tract follows this work of Dr. Fuller and that of Dr. M. L. Rosenheim (THE LANCET, 1935, i., 1032) who found mandelic acid to be a valuable agent in cases of urinary infection unassociated with urinary obstruction. Since Dr. Rosenheim's article appeared Messrs. Boots have received medical evidence from several sources confirming the findings disclosed in Dr. Rosenheim's paper, the urine of the patients being rendered sterile and the improvement in conditions following in a satisfactory manner. It is admitted that for the present the treatment may have to be repeated on occasion, as in some cases it has been found that on discontinuance the urine becomes non-sterile, when the symptoms reappear. The dosage employed has been 12 g. of mandelic acid per day, and the fluid intake should be limited to two pints and the acidity of the urine increased by the administration of ammonium chloride. The standard mixture used in the treatment of cases at University College Hospital contains 3 g. of mandelic acid per ounce just neutralised by sodium bicarbonate and flavoured with lemon. One ounce of this mixture is given four times a day, while 8 cachets, each containing 1 g. of ammonium chloride, are also given during the day. A useful leaflet on the whole subject is supplied by the manufacturers, which includes the warning that careful supervision of the patient is required, lest the drug should act as a renal irritant. The preparation is non-toxic in therapeutic doses.

ERGOMETRINE.—The note published in THE LANCET on August 10th, 1935, p. 353, referring to this preparation is stated to give the impression that Messrs. Allen and Hanburys Ltd. issued ergometrine some time before the drug was issued by British Drug Houses Ltd. British Drug Houses Ltd. recall that on the publication of a paper which appeared in the *British Medical Journal* on March 16th, 1935, Ergometrine B.D.H. was placed upon the market. This fact was announced in a letter published in THE LANCET on April 13th, 1935, from Mr. C. A. Hill, managing director of British Drug Houses Ltd. British Drug Houses Ltd. find that the note under "New Preparations" of August 10th last gives the impression that not only were they not pioneers but were late in the field. In that note Mr. Hill's letter of April 13th ought to have been referred to.

THE MANUFACTURE OF RUBBER BULBS.—The manufacture of rubber bulbs is now meeting with a great variety of needs. In surgical work both thick-necked and thin-necked bulbs are required, for example, in different varieties of ear and nose spray. Nozzles assume different shapes and for convenience some of the bulbs may be made with a flat bottom. The length of the neck may also vary according to needs. We have received from Messrs. David

---

[1] Doors of Hope. By Mabel Hankin. London: John Bale, Sons and Danielsson Ltd. 1935. Pp. 59. 2s. 6d

Moseley and Sons, Ltd., Ardwick, an interesting catalogue of the bulbs which they have on the market, and it may be noted that such a detail as the internal diameter of the neck can be arranged in accordance with requirements.

"THE LOCOMOTIVE GOD."—Miss Clara Leiser, 7, Park-avenue, New York City, writes that she is preparing an authorised biographical and critical study of Prof. William Ellery Leonard and his work. She hopes that psychologists, psychiatrists, or neurologists who have been in communication with him, have met him personally, or have definite opinions concerning his work—"The Locomotive God," published in America in 1927—will assist her and promises to return promptly anything that may be sent to her.

PROSTIGMIN AT REDUCED COST.—Attention has been called in our correspondence columns to the troublesome fact that the present price of this drug places it beyond the reach of the hospital class of patient except for short periods. Messrs. Hoffmann-La Roche inform us that Prostigmin is now available for the treatment of myasthenia cases in a more economical packing. This consists of 5 c.cm. rubber-capped phials of a concentrated solution, each cubic centimetre being equivalent to 2·5 mg. of prostigmin substance. 1 c.cm. of this concentrated solution is therefore equal in potency to 5 ordinary ampoules.

Princess Louise, Kensington, Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.
[illegible] *Maternity Hospital, Marylebone-road, N.W.*—[illegible] rate of £100. Res. Anæsthetist and [illegible] rate of £90. Asst. Res. M.O. At [illegible] Obstet. Surgeon to Out-patients, and [illegible] natal Dept.
[illegible] *Hospital.*—Res. H.P., Res. Cas. O., [illegible] Blagrave Branch Hospital. Each at [illegible]
[illegible] H.S. £150.
[illegible] *ic Hospital, Gt. Portland-street, W.*—[illegible] Country Branch). Each at rate of £150.
Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.
St. Leonards-on-Sea. [illegible] Anæsthetist.
St. Peter's Hospital for [illegible] *Covent Garden, W.C.*—H.S. At rate of [illegible]
St. Thomas's Hospital, S.E.—Surgeon. Also Surgeon to Out-patients.
Salford Royal Hospital.—H.P., two H.S.'s. Also Cas. H.S. Each at rate of £125.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Sheffield Royal Hospital.—Res. Ophth. H.S. Also Res. Asst. Cas. O. At rate of £120 and £80 respectively.
Sheffield Royal Infirmary.—Second Asst. Cas. O. At rate of £80.
Sidcup, Queen Mary's Hospital.—Asst. M.O. £350.
Southampton, Isolation Hospital and Sanatorium.—Jun. Res. M.O. £200.
[illegible] *Royal South Hants and Southampton Hospital.*—
[illegible] *pital.*—H.P. £120.
[illegible] *Hospital for Children.*—Res. Asst. M.O. At rate of £200.
University College Hospital, Gower-street, W.C.—Tuberculosis Officer. £300.
Wakefield, Menston Mental Hospital.—Fifth Asst. M.O. £350.
Warrington Infirmary and Dispensary.—Third Resident. At rate of £150.
West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Asst. Surgeon.
West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each at rate of £100.
Westminster Hospital, Broad Sanctuary, S.W.—"Wander" Scholar. £250.
Wigan, Royal Albert Edward Infirmary.—H.S. At rate of £150.
Willesden General Hospital, [illegible] *N.W.*—Res. Officer. At rate of £100. Also [illegible] M.O. £500.
Wokingham, Berks, Pinewo [illegible] *ooler's Hill,*
Woolwich and District War [illegible] *S.E.*—Res. M.O. £175.
York Dispensary.—Res. M.O. £175.
Zetland County Council.—M.O. and Public Vaccinator. £80.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Sunderland (Durham) (latest date for receipt of applications Sept. 10th) and at Markinch (Fife) (applications before Sept. 17th).

PERFORATION OF THE ŒSOPHAGUS BY SWALLOWED FOREIGN BODIES

BY JOHN E. G. MCGIBBON, M.B. Lond., D.L.O.
HON. LARYNGOLOGIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL

With Radiological Notes by

J. H. MATHER, B.Sc., M.B. Liverp., D.M.R.E.
HON. RADIOLOGIST TO THE HOSPITAL

WRITING in this journal last year Scott-Brown [1] drew attention to the frequency of perforations of the œsophagus by carcinoma, and there is no doubt that neoplasm is the most common cause of such lesions. Perforation by swallowed foreign bodies would probably rank second in frequency, although it is possible that many cases pass unrecognised, as the diagnosis is not always easy and spontaneous recovery may occur. Nevertheless, all such accidents are fraught with danger and any one may end in tragedy.

The three following cases have been observed recently.

CASE 1.—Female, aged 32. On Nov. 29th, 1932, while eating stewed rabbit, she thought a bone had stuck in her throat. She complained of dysphagia and pain on attempting to swallow, but on examination in hospital four hours later no abnormality was found. X ray examination showed a "hitch in passage of opaque paste middle-third of œsophagus—? foreign body in this region." Œsophagoscopy revealed no foreign body, but a small wound of the posterior œsophageal wall 8½ inches from the incisor teeth was visible. The presence of a perforation was not suspected, and the patient was discharged *next day still complaining* of pain on swallowing. The pain persisted after discharge, until she died unexpectedly a week later. Following her discharge from hospital she had been in the care of her *own* family doctor, who had observed no abnormal physical signs except a slightly irregularly elevated temperature. Autopsy showed a purulent infection of the entire retro-œsophageal and retro-pharnygeal spaces. No foreign body was found.

CASE 2.—Male, aged 26. After eating fish on June 17th, 1934, he felt a pain in his throat as if a bone were lodged there. He experienced pain but no difficulty on swallowing. He came to hospital on June 22nd when nothing abnormal was found on examination. X ray report was as follows: "This patient has a large accumulation of gas (air) in his mediastinum pointing to perforation of his pharynx or œsophagus. The upper portion of the œsophagus is displaced laterally. No 'hold-up' of test food." Œsophagoscopy showed a small wound of the posterior œsophageal wall 8 inches from the incisor teeth. The patient was detained in hospital for ten days, during which time he complained of slight dysphagia; but at no time was his temperature raised or his pulse-rate increased. He was last radiographed on July 9th, 1934, when the report was: "Small amount of air still present."

CASE 3.—Female, aged 22. Was eating cod on Nov. 28th, 1934, when she felt a bone stick in her throat. On admission to hospital on Dec. 1st examination showed no abnormality. X ray report: "The œsophagus is displaced forwards and to the left, by a swelling (post-œsophageal) level to 1st to 4th D.V. ? Abscess ? air in mediastinum." Œsophagoscopy showed that at the level of the first dorsal vertebra there was an acute œsophagitis which extended downwards for 2½ inches. No foreign body was seen, nor was any wound of the œsophageal mucosa visible. She was kept under observation in hospital for 14 days, during which time the air was gradually absorbed; and whilst an in-patient she exhibited no rise of temperature or increased pulse-rate.

Wright [2] recently reported three somewhat similar cases. One of his patients died of purulent mediastinitis and empyema; one developed a large mediastinal abscess which pointed and was drained above the clavicle; and one made a spontaneous recovery.

Foreign body perforations may occur either through the cervical or the thoracic portion of the œsophagus. Naturally, owing to the relative inaccessibility of the viscus and its intimate relationship to other important organs, the prognosis is graver, and the patient's chances of recovery are more remote, when the lesion is in the latter situation.

The perforation may be caused by the foreign body itself, by the patient's efforts to rid himself of the intruder, or by faulty or careless technique with instruments. Orton [3] has stated that perforating foreign bodies may be classified as those that perforate at once and those that perforate by erosion. Sharp fragments of bones, fish-bones, pins, and sharp pieces of metal cause immediate perforations. Perforation due to ulceration and erosion is usually due to prolonged sojourn of a foreign body in the œsophagus. It is recognised that insoluble organic matter, such as bone with adherent meat, will cause ulceration more rapidly than inorganic objects such as coins, and that the mortality is higher in cases of immediate than in cases of delayed perforation.

The vulnerability of the œsophagus is well known, and it is probable that a large number of perforations are completed by the patient's own efforts—e.g., straining, vomiting and hawking, pushing fingers and spoons down the pharynx, swallowing hard crusts, &c.—but I can find only one example recorded—viz., Berry's [4] account of a case in which a woman perforated her own œsophagus with a corset stiffener in her efforts to remove a foreign body, with fatal results. Instrumental perforations are probably becoming less common as the dangers of the coin-catcher and probang are more generally recognised. Injuries with the œsophagoscope, however, do occur and Friedenwald and Morrison [5] have recorded a series of such cases, all of which ended fatally.

Anatomy of the Region

The majority of perforations take place into the cellular spaces surrounding the œsophagus, and it will be advisable briefly to describe these.

Throughout the greater part of its course from the pharynx to the diaphragm the œsophagus is contained within a definite fascial space. This space has been called by Furstenberg [6] the "visceral space" (Figs. I. and II. and Fig. III. 8). Anteriorly it is limited by the pretracheal fascia and pericardium; laterally by the carotid sheaths of the cervical fascia and mediastinal pleuræ; and posteriorly by the bucco-pharyngeal fascia and its prolongation downwards on the posterior surface of the œsophagus.

Posteriorly to the pharynx and œsophagus is the so-called "retrovisceral" space (*Fig. I. 4, Fig. III. 9*). This is made up of the retro-pharyngeal and retro-œsophageal spaces. It is bounded anteriorly by the bucco-pharyngeal fascia and its mediastinal prolongation, and the vertical part of the diaphragm; laterally by the carotid sheaths and the mediastinal pleuræ; and posteriorly by the prevertebral fascia and the anterior common ligament of the lower thoracic vertebræ.

The areolar tissue of these spaces is of loose texture, and Lambert and Berry[7] have shown that its processes dip in between the leaves of the pulmonary ligaments, and follow the bronchial tree as far as the tertiary bronchi (Fig. II. a). In their opinion inflammatory involvement of these prolongations gives rise to many of the so-called "root-shadows." It is also in continuity with the areolar tissue outside the pleura—the endothoracic fascia (Fig. II. b). Bernard and Mallet-Guy[8] have demonstrated that the adherence of the parietal pleura to the ribs is strongest at the line of costovertebral articulation, the adherence being much less over the intercostal spaces. Extension of inflammation along this endothoracic path gives rise to characteristic shadows with well-defined but irregularly toothed borders, which appear to widen the mediastinal shadow by X ray examination.

The anatomical continuity of these cellular spaces and of their contained viscera and blood-vessels without the interposition of any fascial barriers allows of definite pathways up and down. Their density, however, is not equal throughout, and von Hacker[9] has pointed out that this is greater in the lower part in as much as inflammatory exudates of the upper portion have no great tendency to spread downwards, whereas they readily migrate upwards towards the neck.

Lerche[10] injected a suspension of barium in buttermilk into the groove between the trachea and œsophagus; with moderate force this was found to extend laterally along the œsophagus and trachea to a few centimetres below the bifurcation where it entered the retro-œsophageal region; and there is boundless clinical and other experimental evidence to prove that the continuity of these spaces is a very real and important one.

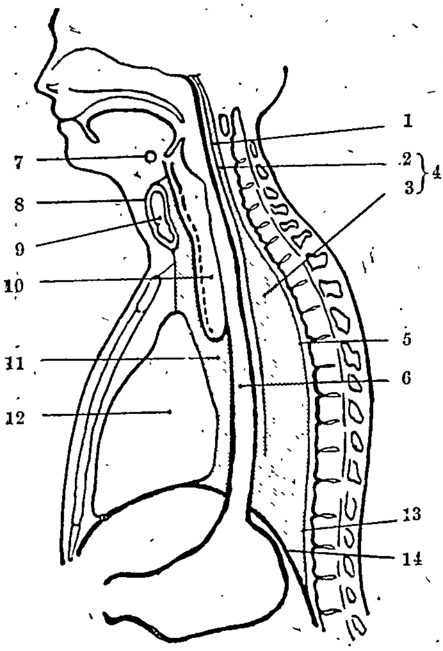

FIG. I.—Diagram of para-œsophageal spaces. (1) Bucco-pharyngeal fascia. (2) Retro-pharyngeal space. (3) Retro-œsophageal space. (4) [illegible] (5) Pre-vertebral fas[illegible] 7) Hyoid bone. (8) P[illegible] Thyroid gland. (10) Trachea. (11) Visceral space. (12) Pericardial sac. (13) Anterior common ligament. (14) Diaphragm.

These cellular spaces are shown diagramatically as the shaded areas in Figs. I.–III. They include the retro-pharyngeal and the retro-œsophageal spaces, the visceral compartment of the deep cervical fascia, a portion of the superior and the entire posterior mediastina; and for the purposes of these notes they will be referred to collectively as the para-œsophageal spaces.

The more important structures contained within, or in relation to, these spaces are the trachea and its bifurcation, the pleuræ and lungs, the aorta, the carotid arteries, internal jugular veins, the azygos veins, thoracic duct, and the pericardium.

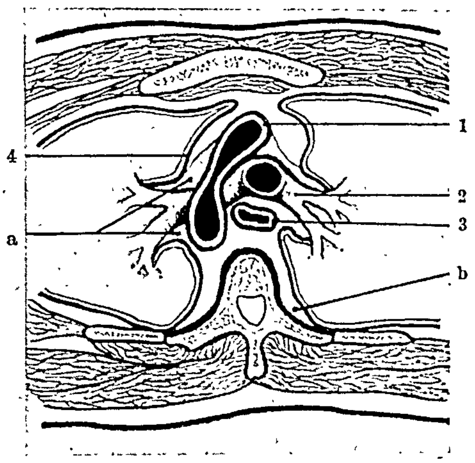

FIG. II.—Diagram of para-œsophageal spaces at level of IVth and Vth dorsal vertebræ. (1) Aortic arch. (2) Right bronchus. (3) Œsophagus. (4) Pleura. (*a*) Tissue extending into pulmonary ligament and hilum. (*b*) Endothoracic fascia.

Symptoms and Signs

Symptoms usually predominate over signs after impaction of a foreign body in the œsophagus, and patients are well aware that "something is stuck in the throat." They complain of pain and dysphagia, which may vary from slight difficulty to complete obstruction. Occasionally such patients may regurgitate or hawk up blood-streaked sputum. Wright[2] has stressed the importance of local tenderness on pressure over the trachea. Tucker[11] considers that it is pathognomonic of the presence of a foreign body in the upper œsophagus if by moving the trachea or larynx towards the point of maximum tenderness, as indicated by the patient, there is a marked increase of pain at this point.

If perforation has occurred, increasing pain is the dominant symptom; but, unless perforation is followed by the escape of air or of infection into the para-œsophageal spaces, it may give rise to no symptoms or signs other than those enumerated above. Lederer and Fishman[12] published an account of a female patient who swallowed over one hundred pins, two hairpins, and five safety-pins, three of which were opened. She manifested no signs or symptoms and voided all the foreign bodies per rectum, yet it is safe to assume that at least one of these sharp bodies perforated the œsophageal wall. This absence of symptoms may be misleading, and Brown[13] has reported two cases of symptomless perforation of the œsophagus, in both of which the patient died subsequently from septic pulmonary complications.

Air may escape through the perforation, giving rise to emphysema. This may occur suddenly owing to straining efforts, or as Seiffert[14] has pointed out it may be brought about gradually by the combined actions of inspiration and a valvular perforation—and not by swallowing air. If the leakage is in the cervical region, it is often accompanied by subcutaneous emphysema, which may be very extensive, reaching down on to the thoracic wall and up into the eyelids and scalp. If it is in the thoracic region there will be a collection of air or gas in the para-œsophageal spaces, which will displace the œsophagus and cause dysphagia. This happened in two of the cases reported above and the X ray appearances are shown in Fig. IV. Uncomplicated para-œsophageal emphysema appears to be a rela-

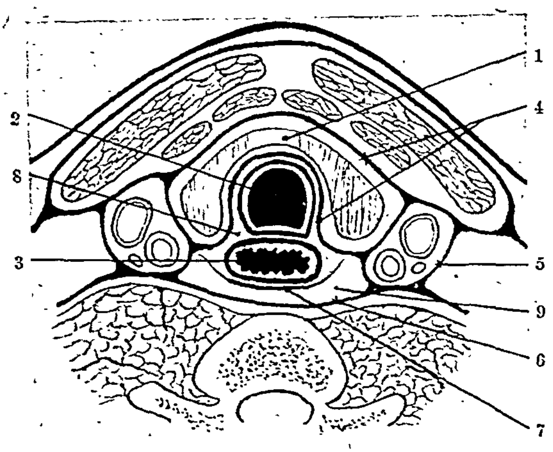

FIG. III.—Para-œsophageal spaces at level of VIIth cervical vertebræ. (1) Thyroid gland. (2) Trachea. (3) Œsophagus. (4) Pretracheal fascia. (5) Carotid sheath. (6) Prevertebral fascia. (7) Œsophageal prolongation of bucco-pharyngeal fascia. (8) Visceral space. (9) Retrovisceral space.

tively benign lesion, although Chevalier Jackson[15] states that it "may prove fatal whether infection follow the leaking air or not." In such cases there are no signs of constitutional disturbance and the only symptoms are dysphagia and pain. It is conceivable, however, that with a massive para-œsophageal collection of air the cardiac and respiratory functions might become considerably embarrassed.

Infection following Perforation

If infection follows a perforation, signs of constitutional disturbance will be manifest and the patient's symptoms become more obvious. Increasing dysphagia with more severe pain, aggravated by attempts to swallow, and a rising temperature and pulse-rate are indications of para-œsophageal infection. Infection usually proceeds to suppuration unless it accompanies gross trauma, when death may ensue before there is time for pus formation.

Infection may be limited and give rise to a localised abscess. This is more likely with a delayed perforation than with an immediate one. In the former case a local peri-œsophageal protective barrier is formed which walls off the abscess cavity from the general para-œsophageal spaces. An abscess so formed may drain into the œsophagus with or without the foreign body in situ. Many observers (Kramer,[16] Tucker,[17] Imperatori,[18] Carmody,[19] Wright,[2]) have recorded cases of para-œsophageal abscess with recovery after endoscopic drainage. Cases have been described in which the entire foreign body had passed through the œsophageal wall and was later recovered from the abscess cavity. In cases in which the abscess cavity becomes shut off from the œsophageal lumen, in the cervical region, the head and neck may be held stiffly towards the affected side and signs of deep pus will become manifest. If drainage is not established the pus may track down into the thoracic portion of the para-œsophageal space.

A localised abscess resulting from a thoracic perforation may track up into the cervical region. Wright,[2] Lerche,[10] and Maclay[20] have reported cases of large para-œsophageal abscess, the two former were opened in the neck and the last in the second right intercostal space, and all recovered. More rarely the abscess may rupture into some portion of the respiratory tract. If this happens, tracheal or bronchial fistulæ may form or pyopneumothorax, pneumonia, pulmonary abscess, or bronchiectasis develop with their train of symptoms. Ballin and Saltzstein[21] report one personal case and quote six others of "transpleural œsophageal fistulæ." These were probably due to extrinsic causes rather than to foreign bodies, but all the patients recovered; and Chaubarrère[22] has recorded a similar case with spontaneous recovery. Orton[3] has reported a case which recovered—the only one out of a series of six—following aspiration of pus from the pleural cavity one month after the perforation.

These localised para-œsophageal lesions after resolution may give rise to fibrous stricture of the œsophagus.

The infection may lead to a generalised cellulitis of the para-œsophageal spaces. It has been stated that this cellulitis may resolve spontaneously and von Eicken[23] has quoted eight cases in which it subsided in this manner. In two other cases recorded, however, following spontaneous resolution, infective thrombo-phlebitis of the internal jugular vein in one (Mosher[24]), and a similar lesion of the azygos vein in the second (Kramer[16]) caused death. Usually a diffuse cellulitis goes on to extensive suppuration throughout the spaces, which always leads to death by septicæmia.

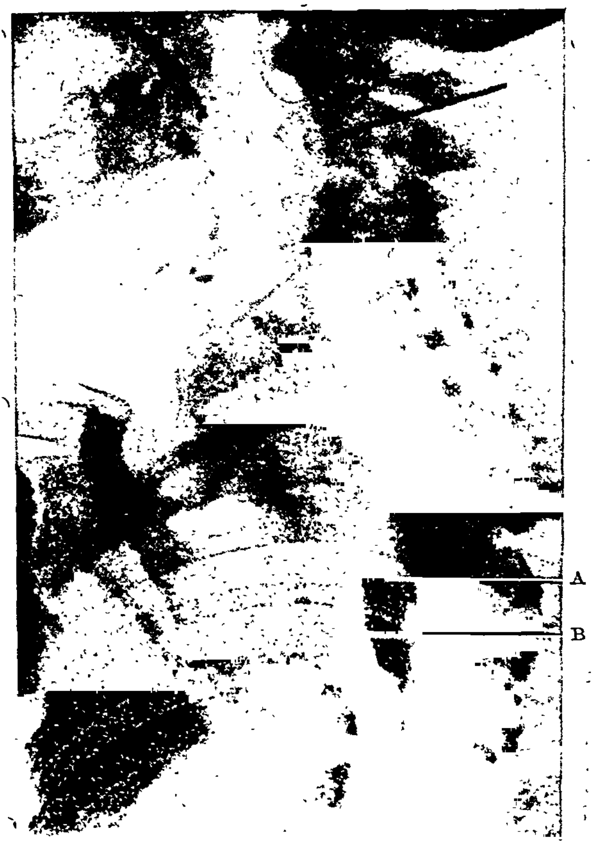

FIG. IV.—A. Localised collection of air in the thoracic para-œsophageal space, displacing forward B, the barium-filled œsophagus.

Fulminating cases appear to be rare except in instrumental perforations, which are usually gross injuries frequently involving the respiratory tract, and accompanied by profound shock. Lyman Richards[25] has concisely and graphically described the results of this accident: "Inside of four hours there is the tragic syndrome of grunting respiration, a tender abdomen, a high fever, and a rapid pulse, which to my mind portends an almost unavoidable tragedy." The foreign body itself may perforate directly into the respiratory tract causing signs and symptoms as described above.

Direct perforation into the aorta or big blood-vessels has been described. Thus Beal,[26] Linn,[27] Doria,[28] and Swain[29] have reported cases of direct perforation by swallowed foreign bodies into the aorta—all of them fatal. Secondary hæmorrhage from the aorta or big vessels may result either from an abscess of the para-œsophageal spaces with subsequent erosion of the vessel wall, or from the prolonged pressure of a smooth rounded object against the vessel. Ter-Oganesjan[30] has collected records of over fifty cases of hæmorrhage from the big vessels, and he reports five of his own.

Diagnosis

Œsophagoscopic diagnosis, except in eroded perforations, is inferential only. A foreign body may be seen actually piercing the œsophageal mucosa, or an abrasion or small punctured wound may be visible. It is, however, often impossible to form an opinion as to whether the entire thickness of the wall has been penetrated. With ulcerated wounds, a view of escaping pus or foul-smelling gas is pathognomonic of perforation. Often the causal relationship of a swallowed foreign body can be presumed only, as it may not be found by œsophagoscopy, or indeed even if the case comes to autopsy. It is wise, therefore, to regard any wound of the mucosa with suspicion and to keep the patient under observation for a few days and to make frequent X ray examinations.

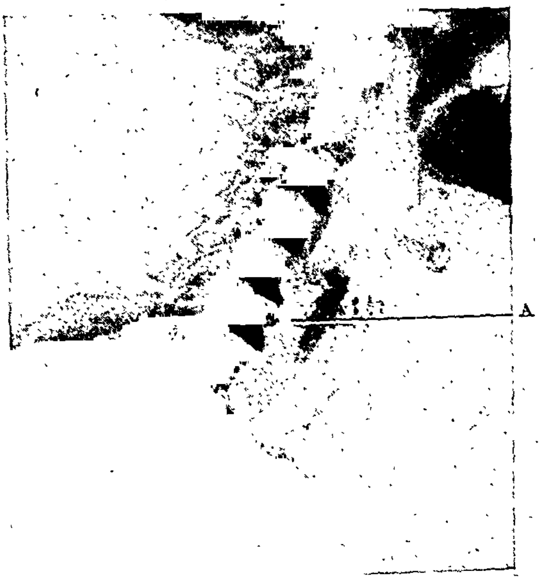

FIG. V.—A. Widening of the post-tracheal space following injury by an upper œsophageal perforation.

At present radiography is our most valuable means of diagnosis. Pancoast[31] has written that "it may be safely stated that abscess of the posterior upper food passage can in most instances be diagnosed roentgenologically before the usual clinical conclusions have been reached or the exact conclusions even suspected, . . ."; and this certainly holds good for perforations by foreign bodies. Thurstan Holland[32] in 1918 formulated a technique for the radiological diagnosis of the presence of non-opaque foreign bodies in the œsophagus. Barium sulphate paste of the consistency of thick cream is given to the patient and its passage through the pharynx and œsophagus watched under the fluorescent screen. The presence of a foreign body or an abrasion of the œsophageal mucosa may be suspected if one or more of the following points are noted: (a) "Hold-up" of opaque material. (b) "Hitch" of opaque material, usually associated with some regurgitation. (c) Retention of a trace of opaque material for 10–30 minutes after swallowing. (d) Retention of a trace of opaque material after swallowing water. (e) Division of the swallowed opaque food into two streams which reunite lower down. This occurs when a flat object lies across the lumen of the œsophagus. (f) "Hold-up" of a small piece of cotton-wool impregnated with barium sulphate paste.

If perforation of the wall has occurred in addition to the above, one or more of the following signs may be observed:—

(a) The presence of gas or air in the para-œsophageal spaces. Iglauer and Ransohoff[33] first drew attention to the X ray appearances of a bubble of air surrounding the point of a perforating foreign body in the cervical region; and the former[34] later stressed the diagnostic importance of the radiological appearance of air in the thoracic region. Such a collection of air in the thoracic para-œsophageal space is illustrated in Fig. IV. (Case 3).

(b) Displacement of the œsophagus. Fig. IV. shows forward displacement of the œsophagus; lateral displacement was also shown in the antero-posterior view of this patient (not reproduced).

(c) Increase of depth of the space between the bodies of the cervical vertebræ and the trachea. Hay[35] has published a table defining the limits of the normality of the width of this space for different ages. Fig. V. illustrates a widening of the post-tracheal space in a patient with a perforating foreign body of the post-cricoid region. This plate is of interest, also, as it shows "lipping" of the bodies of the lower cervical vertebræ—a factor which may have been contributory to the impaction of the foreign body.

(d) In the thoracic region by the presence of a tumour, probably sausage-shaped, in the para-œsophageal space. Since these notes were written Lawson Whale[36] has reported the post-mortem findings in a case of mediastinal abscess of unknown ætiology, and it is interesting to note that Dr. H. H. Sanguinetti describes this abscess as "shaped like a small curved sausage." Cases have been recorded in which opaque material has been observed to completely or partially fill a para-œsophageal abscess cavity.

(e) Widening of the mediastinal shadow in the antero-posterior view—as mentioned above this is probably due to inflammatory involvement of the endothoracic fascia.

(f) The passage of opaque material from the œsophagus into the tracheo-bronchial system or other part of the respiratory system.

(g) If a small quantity of lipiodol is swallowed the shadow of a streak of oil seen outside the œsophagus is proof positive of an œsophageal perforation (Iglauer[34]).

Prognosis and Treatment

It is impossible to estimate the frequency of foreign body perforations as numerous cases remain undiagnosed, but there is a wealth of evidence to prove the gravity of this accident.

Myerson[37] has reported seven cases of perforation of the cervical œsophagus of which four died; and one thoracic perforation which recovered. Lederer and Fishman[12] report two definite and one presumptive cases of perforations—all with recovery. King[38] reports six cases, four cervical and two thoracic, all of which recovered.

Orton[3] reports six cases of para-œsophageal infection, five of which died. Wright[2] records three cases with one death, and the present paper three cases with one death.

Considering the œsophageal foreign body cases collectively, the mortality-rate varies very much. Schlemmer[39] reported 529 cases which had been treated in the period 1909–1919 with 15 deaths. Killian[40] reported 389 cases for the period 1900–1922 with 70 deaths. This high mortality is due probably to inclusion of the earlier years when endoscopic removal was in its infancy and comparatively unknown. Jackson[41] reported 204 cases for a period up to 1923 with 3 deaths. Iglauer and Ransohoff[33] from their investigations concluded that serious complications occur in about 3–2 per cent. of cases of foreign bodies in the œsophagus.
